Case presentation: A 47-year-old patient, diagnosed with Systemic Lupus Erythematosus (SLE) since 2016, was referred to the neurologist complaining of mild dysarthria, which began in 2017. The condition, however, progressively worsened over the years, accompanied by difficulty walking due to weakness in the lower limbs, insomnia and a mood disorder. Since 2019, she has also reported a frontal, throbbing, vertex headache with associated nausea, with episodes around 2 to 3 times a week and partial relief with dipyrone. He also had an episode of loss of consciousness preceded by tremors in the right eyelid in 2021. On physical examination, there was decreased tactile sensitivity in the left upper limb and left hemiface, as well as a gait with a broad base and a staggering gait in the left lower limb. Computed tomography (CT) of the skull showed gross calcifications affecting the frontal, occipital parietal and temporal lobes, as well as the thalamus, striatum, globus pallidus, cerebellum and midbrain. Brain MRI confirmed the CT scan findings. **Discussion:** Fahr's syndrome is a rare secondary condition of intracranial calcification, marked by its neurodegenerative nature, and is often underestimated and underdiagnosed. The patient in question had neurological symptoms, including motor deficits, headache, dysarthria, as well as psychiatric disorders such as mood disturbances. Among the main causes of this syndrome - unlike the primary form, which is hereditary - are hypoparathyroidism, as well as infections such as cytomegalovirus and HIV. The patient in this case had no similar family history, and all possible secondary causes were ruled out. It is therefore assumed that these calcifications were caused by SLE. CT is the preferred method for locating and assessing the extent of cerebral calcifications, which are identified as hyperdense lesions. The pathogenesis of these findings is unclear and there are no confirmed hypotheses, but possibly the calcifications result from repeated episodes of venous inflammation with focal immunological demyelination. A likely mechanism could be the extravasation of proteins from venous vessels with neurotoxic and pro-calcification properties. Treatment is based on symptoms and the underlying cause, and the prognosis is variable, with a tendency for symptoms and calcification to worsen. **Final comments:** We report this case considering the rarity of symptomatic Fahr's syndrome in a patient with SLE. The underlying mechanism of calcification in this context is not known, but it is suggested that it is due to ongoing venous inflammation. This report highlights the importance of considering Fahr's syndrome as a possible explanation for neurological manifestations in patients with SLE. This approach, in addition to broadening the diagnostic spectrum, improves understanding of the neuropsychiatric manifestations associated with SLE, allowing for more comprehensive and precise clinical management.

Diffuse brain involvement in lymphomatoid granulomatosis

Marco Antônio Delazeri[1], Gustavo Henrique Tomasi[2], William Alves Martins[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil. [2]Hospital São Vicente de Paulo, Curitiba PR, Brazil.

Correspondence: Marco Antônio Delazeri; Email: marco.delazeri@outlook.com.

Case presentation: A 34-year-old immunocompetent woman had history at lung lymphomatoid granulomatosis (LYG) associated with Epstein-Barr virus (EBV), diagnosed in 2010 after a lung segmentectomy, treated with cyclophosphamide and methylprednisolone over a period of six months. At that time, she was carefully investigated with imaging tests in order to rule out LYG at other sites. Brain magnetic resonance imaging (MRI) findings showed infiltration of cranial nerves and meningeal enhancement, remitting after treatment. Five years later she seemed apathic and had suicidal ideation, also presenting disperceptive episodes. She was admitted in a psychiatric facility for a few days, after which she left home. For the next seven days, she progressed with slurred speech, ataxia, left hemiparesis, and motor ocular paralysis. Neurologycal exam showed left-side weakness, left cranial nerve paresis, horizontal nystagmus, left hypoesthesia and right internuclear paralysis. Cerebrospinal fluid was normal. MRI is described in Fig 1. It was started pulse therapy with methylprednisolone for seven days, with no clinical improvement. Hematologists considered this clinical condition as a progression of the LYG and patient received systemic chemotherapy (CHOP scheme from March 2015 at June 2015) and intratechal chemotheraphy. She showed clinical improvement of symptoms after chemotherapy with reduction of lesions in MRI and currently remains neurologically stable with no CNS recurrence. **Discussion:** Lymphomatoid granulomatosis (LYG) is a rare B-cell lymphoproliferative disorder, normally associated with Epstein-Barr Virus (EBV), that involves especially the lungs, but may affect skin and central nervous system (CNS) during its course. Nonetheless, primary CNS-LYG may represent a lymphoproliferative disorder with low-grade T cell malignancy, contrary to systemic LYG, which is composed of EBV-positive B cells. CNS-LYG has a variable spectrum of lesions at MR imaging. In a study, multiple focal lesions that involve the white matter, the deep gray matter, or the brainstem represent the most common abnormalities, but the hyperintensity on the T2-weighted MRI was not specific to this condition. The punctate and/or linear enhancement in these lesions appears to be a characteristic finding of lymphomatoid granulomatosis in the brain. This enhancement is related to the perivascular and vascular wall infiltration by pleomorphic and lymphoid cells, what was previously shown in biopsy specimens of the brains. Lesion morphology is a nodular infiltrate with polymorphous mononuclear cell, vascular infiltration and often necrosis permeated with CD20-positive B-lymphocytes in a background of CD3-positive small T lymphocytes and scattered admixed plasma cells and histiocytes. **Final comments:** There is scarce knowledge about LYG progressing to CNS and, therefore, the pathophysiology and phenotype are not well defined. Our case highlights its presentation and response to proper treatment.

Diffuse cortical laminar necrosis in dengue encephalitis and status epilepticus: rare complications of a common disease in a climate crisis scenario

Leticia Bassani Devens[1], Giuseppe Dick Bonato[1], William Alves Martins[1]

[1]Hospital São Lucas, Departamento de Neurologia, Porto Alegre RS, Brazil.

Correspondence: Leticia Bassani Devens; Email: leticiabassanidevens@gmail.com.

Case presentation: We present a 72 year-old woman transferred to our tertiary hospital after 5 days of headache, diarrhea and high fever followed by 4 days of continuous conscious level impairment. Dengue infection was diagnosed after NS1 antigen positive test. A first episode of generalized seizure led to tracheal intubation and transference to ICU. Medical history included well controlled hypertension, diabetes and hypothyroidism. At arrival in our tertiary hospital, she had no arousal to stimuli and preserved brainstem reflexes. Brain CT scan was uneventful, and first CSF analysis showed 26 leucocytes/mm3 with neutrophilic predominance, 102mg/dl proteins, 3,2mg/dl lactate, and normal glucose ratio. Search for acid-fast bacilli and neoplastic cells, bacterial and fungal cultures and HSV PCR were negative. CSF results led to initiation of ampicillin, ceftriaxone and acyclovir. EEG showed severe cortical encephalopathy with frequent sharp waves in anterior quadrants compatible with clinical seizures. Despite levetiracetam and continuous IV midazolam introduction, continuous video-EEG revealed severe encephalopathy and frequent bilateral temporal focal non-clinical seizures. Propofol sedation was added and levetiracem increased. Subsequent EEG showed severe background suppression without further epileptic activity. Brain MRI had diffuse pachymeningeal enhancement and thickening, slight cortical signal increase, restricted diffusion and enhancement compatible with laminar necrosis. After 12 days of adjustments (levetiracetam 3g/day, clobazam 10mg/day, phenytoin 200mg/day, carbamazepine 1200mg/day), and no more epileptic events, propofol was tapered. Serum dengue IgM was positive, and CSF PCR negative. Minimal clinical improvement prompted empirical methylprednisolone 1g/day for 5 days without change in clinical status. New brain MRI after 16 days showed signal alteration and diffuse enhancement in cortex and temporal amygdalae. She was able to receive domiciliary care after traqueostomy and diet adjustment, being discharged with mRS 5/6. **Discussion:** Although patient showed negative CSF dengue PCR, this clinical case is compatible with dengue encephalitis. Dengue infection is highly prevalent in Brazil, and its Southern region was under a severe outbreak when this patient developed symptoms. Although not commonly recognized, dengue is regarded as the second most common cause of infectious encephalitis in countries where it is endemic. Pathogenesis is not fully understood, and dengue virus neurotropism is still questioned. **Final comments:** Dengue encephalitis is challenging: no specific treatment is available, and support measures are advised. Using video-EEG to determine epileptic control and safe sedation tapering prevents further continuous epileptic activity damaged. New treatments options are warranted, especially due to current environmental changes that lead to dengue vectors increase, turning a rare manifestation into a likely complication.

Digital analysis of immunostaining and tissue distribution of the R132H mutant form of isocitrate dehydrogenase 1 in diffuse low or high-grade adult astrocytomas

João Vitor Gerdulli Tamanini[1], Arethusa de Souza[1], Guilherme Rossi Assis-Mendonça[1], Enrico Ghizoni[1], Helder Tedeschi[1], Mateus Dal Fabbro[1], Leandro Luiz Lopes de Freitas[1], Marcus Matsushita[2], Roger Frigério Castilho[1], Fabio Rogerio[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.
[2]Faculdade de Medicina Franco Montoro, Cachoeira de Cima SP, Brazil

Correspondence: João Vitor Gerdulli Tamanini; Email: jvgtamanini@yahoo.com.br.

Background: Diffuse gliomas are common primary tumors of the central nervous system. The current diagnosis of such lesions, which include astrocytomas, depends on molecular features, including the presence of mutation in the enzyme isocitrate dehydrogenase(IDH). The wild isoforms of IDH-1(cytosolic) and 2(mitochondrial) convert isocitrate into α-ketoglutarate(αCG), promoting the reduction of NADP+ to NADPH. Both αCG and NADPH are antioxidants. The most common mutant form of IDH1(R132H) has a gain of function in which αCG is converted into D2-hydroxyglutarate, an oncogenic compound that consumes NADPH. Thus, a functional relationship is observed between IDH1, IDH2 and IDH1R132H. **Objective:** To perform neuropathological characterization of diffuse astrocytomas in adults as well as to investigate the immunostaining and possible alteration in tissue distribution of IDH1, IDH2 and IDH1R132H, considering the presence of the R132H mutation and histological grade. **Methods:** We evaluated 25 surgical specimens from adults with diffuse gliomas, which were molecularly and immunophenotypically characterized as astrocytomas of low- or high-grade (2 (n=10) or 4 (n=15), respectively), according to the World Health Organization current criteria. We also analyzed the immunostaining pattern of IDH1, IDH2 and IDH1R132H, as well as their tissue distribution (mean % of positivity assessed by using ImageJ® software), considering the R132H mutation and the lesion histological grade. **Results:** Regarding age at diagnosis(< or ≥55 years) and R132H immunopositivity, the lesions were classified as: astrocytoma, IDH-mutant, grade 2 (5/25); astrocytoma, not otherwise specified (NOS), grade 2 (5/25); glioblastoma, IDH-wildtype, grade 4 (9/25) or astrocytoma, NOS, grade 4 (6/25). IDH1, IDH2 and IDH1R132H showed a diffuse cytoplasmic staining pattern, regardless of grade. When comparing low- and high-grade lesions, the tissue distribution of IDH1 was lower in the former (14.20±1.70% and 16.40±1.60%, respectively; p=0.0051), no difference being observed for IDH2 (15.10±1.80% and 14.90±2.0%; p=0.6773) and R132H (5.20±5.60% and 1.80±4.80%; p=0.1234). Specifically, low-grade lesions with (5/10) or without (5/10) the mutation showed no differences regarding tissue distribution of IDH1 (14.40±2.30% and 14.10±0.90%, respectively; p=0.2963) or IDH2(15.60±1.0% and 14.70±2.40%; p=0.8345). Irrespective of the histological grade, there was correlation neither between tissue expressions of R132H and IDH1 nor between R132H and IDH2. **Conclusion:** In the present series, IDH1R132H was more frequent in grade 2 than in grade 4 lesions. Furthermore, our data suggest that (1) such mutation does not interfere with tissue expression of wild-type IDH1 and IDH2, and (2) the wild-type IDH1 allele would ensure protein synthesis at physiological levels.

[2]Universidade Federal de São Paulo, São Paulo SP, Brazil.
[3]Beneficência Portuguesa, São Paulo SP, Brazil.

Correspondence: Millene Rodrigues Camilo; Email: millene.camilo@gmail.com.

Background: Accurate syndromic and topographic diagnosis in Vascular Neurology is crucial for appropriate clinical management and therapeutic interventions. However, significant gaps in medical training hinder precise diagnoses. Educational digital tools may bridge these gaps, but few have undergone rigorous scientific validation. **Objective:** To validate the LouiS digital tool for syndromic and topographic diagnosis in Vascular Neurology. **Methods:** Vascular neurologists developed algorithms based on literature review and consensus. An independent programmer created the LouiS interface. A cross-sectional study was conducted where residents, fellows, professors, and neurology students, randomized into two groups, used the tool or not to diagnose 40 hypothetical cases. Diagnostic accuracy and user satisfaction were evaluated. Data were treated ethically and confidentially. User satisfaction was assessed in terms of time spent, quality of questions, ease of use, and platform friendliness. **Results:** LouiS tool is expected to increase diagnostic accuracy and user satisfaction, proving its educational efficacy in Vascular Neurology. The app has already been created and is available at https://louis-stroke.com/. The tool encompasses 171 symptoms, 98 syndromes, 170 images, and 4629 diagnostic possibilities, aiming to improve diagnostic precision and user experience. **Conclusion:** LouiS has the potential to significantly improve diagnostic accuracy in Vascular Neurology, addressing critical educational gaps. There are no direct risks or benefits to participants.

Directional deep brain stimulation in the management of Parkinson's disease: efficacy and constraints - an analytical appraisal

Mayara Tszesnioski Maçaneiro[1], Ana Clara Azevedo[1], Bruna Maurício Poerner[1], Milena Dangui da Silva[1], Andrei Koerbel[1]

[1]Universidade da Região de Joinville, Joinville SC, Brazil.

Correspondence: Mayara Tszesnioski Maçaneiro; Email: mayaratm.tsz@gmail.com.

Background: Deep brain stimulation (DBS) is a widely employed treatment for Parkinson's disease. However, conventional DBS utilizing ring-shaped leads can often result in undesirable side effects by stimulating nearby brain structures, thus limiting its effectiveness. To address this issue, a novel DBS electrode was developed to allow for directional stimulation, avoiding neighboring structures. **Objective:** This literature review aims to analyze the disparities between conventional and directional DBS and discuss the benefits and limitations associated with this innovative electrode design, focusing on the stimulation-induced side effects it can or cannot mitigate. **Methods:** A comprehensive search was conducted in MEDLINE/PubMed, ScienceDirect, and EBSCO databases using the Boolean search criteria: "Deep brain stimulation" AND "Parkinson" AND "Directional." Following the application of inclusion and exclusion criteria, the selected articles were downloaded for full-text reading. Subsequently, the results were organized and analyzed to compose this article. **Results:** Numerous studies have demonstrated that directional DBS effectively reduces side effects associated with brain stimulation, prevents the stimulation of non-targeted structures, and expands the therapeutic window, among other advantages. However, it has been observed that directional DBS may be more challenging to program and requires higher energy consumption. Furthermore, there is a lack of standardization among different manufacturers of directional DBS electrodes. Various stimulation-induced side effects, including dysarthria, dyskinesia, paresthesias, and symptoms of pyramidal tract activation, have been shown to be mitigated with the use of directional DBS. Moreover, directional electrodes offer a wider therapeutic window and a reduced incidence of undesired effects, requiring the same or lower minimum current for symptom relief compared to conventional DBS. **Conclusion:** The utilization of directional leads in DBS offers numerous advantages over conventional electrodes without significant drawbacks for patients undergoing directional DBS therapy.

Discontinuation of disease-modifying drugs in older patients with multiple sclerosis: an observational study

Camila Lopes Figueiredo[1], Marcelle Sanjuan Ganem Prado[1], Maria Clara Motta Barbosa Valente[1], Leticia Machado Dumont[1], Rafael Chaves Claudino de Queiroga[1], Cicero Rodrigues Veloso[1], Filipe Brito Ferraz da Silveira[1], Eliana Tomomi Shimabukuro da Cunha[1]

[1]Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Camila Lopes Figueiredo; Email: camila04_lopes@hotmail.com.

Objective: To evaluate the discontinuation of disease-modifying drugs (DMTs) in patients with multiple sclerosis (MS) aged 55 years or older. **Methods:** A retrospective observational study of 42 MS patients aged 55 years or older, followed at the demyelinating disease outpatient clinic of the Santa Casa de Misericórdia de São Paulo Hospital, Brazil, for at least 2 years, with clinical and radiological stability of the disease. Data was collected between March and April 2024. **Results:** Of the 42 patients, 33.3% (14) discontinued DMTs, 64.3% (9) due to disease stability, 7.1% (1) due to adverse effects, 7.1% (1) due to lack of medication, 14.3% (2) by their own decision, and 7.1% (1) due to other causes. The remaining 66.6% (28) remained on DMTs, the main ones being Beta-interferon, Dimethyl Fumarate, and Natalizumab. **Conclusion:** Patients who discontinued DMTs for any reason maintained stable disease, with no new radiological activity or worsening of EDSS. DMT discontinuation did not appear to influence clinical outcomes, corroborating the perception of the limited effect of immunomodulation in older patients. Keywords: Multiple sclerosis, disease-modifying drugs, discontinuation, older patients, clinical outcomes.

Disease burden and outcomes in adult patients with Duchenne muscular dystrophy

Clara Gontijo Camelo[1], Raquel Diógenes Alencar[1], Mariana Cunha Artilheiro[1], Cristiane de Araujo Martins Moreno[1], Joemir Jábson da Conceição Brito[1], Karlla Danielle Ferreira Lima[1], Maria Bernadete Dutra de Resende[1], Marcos Antônio Veloso de Albuquerque[1], Umbertina Conti Reed[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Clara Gontijo Camelo; Email: claragc@gmail.com.

Background: Duchenne muscular dystrophy (DMD) is an inherited X-linked recessive neuromuscular disorder caused by variants in the DMD gene, resulting in the absence of the structural protein dystrophin. This condition leads to progressive limb-girdle muscle weakness, loss of ambulation (LOA) by the ages of 10 to 14 years, dilated cardiomyopathy, and respiratory insufficiency. Over the past 30 years, the natural history of individuals with DMD has evolved significantly due to implementing standards of care (SoC), including ventilatory support, glucocorticoid treatment, proactive cardiac intervention, and multidisciplinary care. However, the disease burden and outcomes for adult patients with DMD remain inadequately described. **Objective:** This study aims to describe the disease outcomes and burden in adult patients with DMD followed by a specialized care service. **Methods:** A retrospective cross-sectional study was conducted by reviewing medical records. Inclusion criteria were: (1) patients who lost ambulation before the age of 13 years (clinical diagnosis of Duchenne); (2) patients who lost ambulation by the age of 16 years at the latest (intermediate clinical presentation) but had loss-of-function variants (out-of-frame and nonsense); (3) patients older than 18 years old; (4) patients using steroids: prednisolone or Deflazacort, but with variable doses. **Results:** Thirty patients were included in the study. Eighteen out of thirty patients (60%) had deletions, six out of thirty had duplications (20%), and six out of thirty (20%) had point mutations in the DMD gene. The current average age of the patients is 22.5 years (SD: ±3.9; range: 18-33 years). On average, the patients used corticosteroid therapy for 12.8 years (SD: ±4.9; range: 5-24 years). The average age of LOA was 12 years (SD: ±2.2 years; range: 7-15 years). Twenty patients (66.6%) had cardiomyopathy with an ejection fraction (EF) of less than 50%, and sixteen out of thirty patients (53.3%) required more than one heart medication. Eleven patients (36.6%) used nocturnal non-invasive ventilation, with three out of thirty patients (10%) requiring daytime non-invasive ventilation. Five patients (16.6%) had been hospitalized for pneumonia at least once. Eight patients (26.6%) experienced dysphagia, necessitating adjustments to the consistency of their diet. Seventeen patients (56.6%) had osteoporosis, and nine (30%) had fractures, with three (10%) experiencing more than one fracture. **Conclusion:** DMD is a disease with a high burden, and adult care is complex, requiring a multidisciplinary team. Special attention should be given to the cardiac, respiratory, and nutritional aspects and the development of osteopenia due to the long-term use of corticosteroids and hypomotility.

https://doi.org/10.5327/CBN240562

Disorders of nerves, nerve roots and plexuses in Brazil: an epidemiological analysis over the last 5 years

Matheus Prado dos Santos[1], Rafael Hendrick Freitas de Paula[1], Luan Nascimento Pereira de Amorim[1], Fernando Silva Galvão[2], Daniel Lucas Araujo Ramos[2], Paola Carolina Santos Foinkinos[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil. [2]Universidade Federal do Pará, Belém PA, Brazil.

Correspondence: Matheus Prado dos Santos; Email: imatheusprado@gmail.com.

Background: Disorders involving nerves, nerve roots, and nerve plexuses are significant in the context of public health due to their high prevalence in the Brazilian population and their impact on the quality of life of affected individuals. These conditions can range from difficult-to-control pain to loss or reduced functionality in the affected region. In this context, it is necessary to analyze and discuss hospitalizations and deaths related to nerve, root, and nerve plexus disorders in Brazil. **Objective:** To analyze the epidemiological profile of disorders of the nerves, nerve roots, and nerve plexuses in Brazil from 2019 to 2023. **Methods:** This is an ecological, cross-sectional, descriptive, and analytical study with a quantitative approach, carried out by collecting secondary data from the Department of Informatics of the Unified Health System (DATASUS) from 2019 to 2023. The following variables were analyzed: number of authorizations for hospital admissions, average cost per admission, mortality rate, nature of care, number of admissions, and number of deaths. **Results:** From 2019 to 2023, there were 148,553 hospitalizations for nerve and nerve root disorders in Brazil, with an approximate annual average of 29,710 hospitalizations. According to region, during this period, there were 4,176 hospitalizations in the North (2.81%), 19,917 in the Northeast (13.40%), 67,589 in the Southeast (45.49%), 45,777 in the South (30.81%), and 11,094 in the Midwest (7.46%). The number of hospitalizations per year was 30,858 in 2019 (20.77%), 18,422 in 2020 (12.40%), 21,245 in 2021 (14.30%), 35,901 in 2022 (24.16%), and 42,127 in 2023 (28.35%). The average cost per hospitalization was 1,078.21 reais in the North, 932.15 reais in the Northeast, 621.03 reais in the Southeast, 664.76 reais in the South, and 553.56 reais in the Midwest. The mortality rate was 1.72 in the North, 0.35 in the Northeast, 0.88 in the Southeast, 0.15 in the South, and 0.14 in the Midwest. Regarding the type of care, 115,171 hospitalizations were elective, and 33,382 were emergencies. In terms of admissions by gender, there were 36,833 male patients (24.8%) and 111,720 female patients (75.20%). Finally, the number of deaths by gender was 458 in males (56%) and 359 in females (44%), totaling 817 deaths. **Conclusion:** During the study period, the North region, despite having the lowest number of hospitalizations, had the highest average cost per hospitalization and the highest mortality rate. This highlights the need for improvements in health services in the North of Brazil, showing a significant contrast when compared to the Southeast. It is therefore essential that health professionals are well-informed about the epidemiological profile of individuals affected by disorders of the nerves, nerve roots, and nerve plexuses in Brazil.

https://doi.org/10.5327/CBN240563

Dissection of the common carotid artery and anatomical variant of anterior cerebral artery leading to ischemia in multiple cerebral vascular territories

João Vitor Assumpção Silva[1], Giovanni Caniçali Simões[1], André Luiz de Rezende[1], Marcele Schettini de Almeida[1], Sônia Maria César Azevedo[1]

[1]Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo SP, Brazil.

Correspondence: João Vitor Assumpção Silva; Email: joaosilva7890@hotmail.com.

Case presentation: A 67-year-old man, previously diabetic, presented to the emergency department with sudden onset of complete right hemiplegia and anesthesia, global aphasia, and a National Institute of Health and Stroke Scale (NIHSS) score of 18, within the time frame for potential chemical thrombolysis. Immediate CT scan of the head showed no signs of recent hemorrhage or ischemia. Cardiological investigations with ECG and TTE revealed no significant abnormalities. Further MRI imaging revealed ischemic areas in the left middle cerebral artery territory, correlating with the patient's deficits, along with small areas of recent ischemia in both medial frontal lobes. MRA identified kinking, and thread-like flow of the left internal carotid artery (ICA) (1.8 cm distal to the carotid bulb), consistent with vessel dissection, and an eccentric thrombus causing stenosis in the mid-third of the left internal carotid artery (2.7 cm above the kinking). Additionally, we found a hypoplasia of the A1 segment with both anterior cerebral arteries (ACA) originating from the left ICA, explaining the bilateral frontal ischemias. We decided for treatment with dual antiplatelet therapy based on the service's experience in treating cervical vessel dissection-associated strokes. After just 4 days of hospitalization, the patient's NIHSS score improved to 3, with mild right paresis and hypoesthesia, and complete recovery of language. **Discussion:** Cervical artery dissection (CeAD) represents an uncommon cause of stroke, estimated at 2.6 to 3 cases per year. This condition is predominantly spontaneous or related to minor trauma. CeAD is responsible for about 25% of strokes in patients under 50 years old. Typically, CeAD occurs due to rupture of the vessel's intimal layer and formation of a mural thrombus. Both dual antiplatelet therapy and anticoagulation can be used for secondary prevention of CeAD-related strokes, but consensus on the optimal approach is still needed. The absence and hypoplasia of the A1 segment are among the most characterized and studied variations of the ACA. These anomalies of the ACA have a prevalence between 9% and 10%. This alteration results in the medial frontal lobes of both hemispheres being primarily irrigated by the carotid circulation from only one side. Consequently, ischemic events in these cases can present with bilateral frontal infarcts, as observed in our patient, leading to disabling deficits. **Final comments:** Stroke caused by carotid artery dissection and those related to anatomical variants of ACA are unusual. The case presented demonstrates the occurrence of both in a single patient, which adds interest for study. It is imperative for neurologists to be vigilant for such variations, especially when encountering strokes with atypical presentations. There is still no definitive consensus for secondary prevention of CeAD-related strokes, and case reports like this one are crucial for ongoing discussions among specialists.

Disseminated cryptococcosis in immunocompetent patients: a therapeutic challenge

Valeska Forza Julio[1], Waldemar Carlos Barros de Algemiro[1], Juliana Bruneli Secchin Algemiro[1], Yasmin Oliveira Gil de Almeida[1], Ramana Scardua Jonas[1], Thiago Caetano Valladão de Azeredo[1], Ricardo Coelho Miranda[1], Marcos Paulo Travaglia[1], Thais Oppenheimer Pitanga de Rezende[1]

[1]Hospital Evangélico de Cachoeiro do Itapemirim, Cachoeiro de Itapimirim ES, Brazil.

Correspondence: Valeska Forza Julio; Email: valeskafj@hotmail.com.

Cryptococcosis is a fungal disease caused by the inoculation of Cryptococcus sp, primarily affecting the lungs and brain of immunocompromised individuals. Although uncommon, it can also occur in immunocompetent individuals, as will be discussed in the following study. The case involves a young patient, 32 years old, with no comorbidities, who was referred to the emergency room due to a severe, medication-refractory holocranial headache, associated with intractable nausea and vomiting, and drowsiness. The patient reported the onset of pain about two months ago with progressive worsening. Upon neurological examination at admission, the patient presented with drowsiness, mental confusion, generalized weakness, hyperreflexia of the lower limbs with a bilateral triple flexion plantar response, Hoffmann's sign on the right, no alteration in superficial or deep sensitivity, and absence of meningeal signs. Cranial magnetic resonance imaging revealed countless supra and infratentorial cystic lesions. The diagnosis of disseminated cryptococcosis was made through cerebrospinal fluid puncture, skin biopsy, and lung biopsy. Specific treatment was initiated 10 days after admission (following fungal culture growth on the slide) with amphotericin B and fluconazole 1,200 mg/day. Currently, the patient remains hospitalized under the care of the medical team.

Case presentation: Male, 41 years old, with Sézary syndrome (a variant of Non-Hodgkin Lymphoma), currently on Interferon, Prednisone, and Doxepin, manifesting retro-orbital headache and paravertebral lumbar pain, associated with anuria and global paresis predominantly in the lower limbs. Symptoms began 5 days prior, and presented reduction in the level of consciousness since the previous day. Physical examination revealed xerostomia, drowsiness and confusion, dysdiadochokinesia, intention tremor, proportional paraparesis in the lower limbs (4/5), and patellar hyporeflexia. Cranial computed tomography (CT) scan with any particularities, and cerebrospinal fluid (CSF) showed xanthochromia, high red blood cell concentration, and lymphocytic pleocytosis, leading to the hypothesis of meningitis and encephalitis. The patient was empirically treated with Ceftriaxone, later switched to Tazocin, and Acyclovir. Two days later, with progressive deterioration in the level of consciousness, the patient was transferred to the intensive care unit, remaining drowsy, without effective communication, and with global hyporeflexia, experiencing a single seizure. Developed respiratory failure 5 days after, requiring endotracheal intubation. A new CSF analysis revealed the presence of malignant cells, suggesting neoplastic dissemination, and a cranial magnetic resonance imaging (MRI) showed diffuse leptomeningeal enhancement and thickening of the cranium, cervical, and dorsal spine. In light of this suspicion, the oncology team was contacted to repatriate the patient to the institution where he was undergoing treatment. **Discussion:** Sézary syndrome (SS) is a chronic lymphoproliferative disorder, part of the group of cutaneous T-cell lymphomas. Its rare, most commonly characterized by skin lesions, scaly eruptions, and pruritus. Although uncommon, metastasis can occur, and particularly, the central nervous system is a rare site for such dissemination. Diagnosis and investigation of SS are primarily through blood tests and skin lesion biopsies. Staging is based on the assessment of skin involvement and whether there is lymph node or visceral involvement. SS can be treated with a wide range of chemotherapeutic, immunotherapeutic, and biological modifying agents, which may or may not be combined with skin-directed therapy, including topical agents, phototherapy, and radiotherapy. **Final comments:** The SS subtype itself is a rare manifestation of T-cell lymphomas, and its leptomeningeal dissemination is a peculiar finding. Therefore, recognizing symptoms caused by CNS metastasis can be challenging, making it essential to remain vigilant for possible lymphoma metastasis and maintain a multidisciplinary follow-up beyond treatment, aiming to prolong patient survival despite the unfavorable prognosis when neurological involvement is present. If necessary, therapy using agents that penetrate the CNS can be pursued for a more lasting remission.

Correspondence: Samia Talise El Horr de Moraes; Email: samiatalise1@gmail.com.

Distal hereditary motor neuropathies (dHMNs) form a clinically and genetically heterogeneous group of disorders, characterized by muscle weakness and atrophy predominantly in the distal parts of the limbs due to the progressive degeneration of motor neurons in the spinal cord. This disease is caused by mutations in the HSJ1 (DNAJB2) gene, which encodes a co-chaperone member of the heat shock protein family. To describe a new phenotype of a rare recessive distal hereditary motor neuropathy with HSJ1 chaperone mutation, we present a case of a 45-year-old male patient who developed a progressive gait disorder with lower limb weakness, bradykinesia, followed by gait ataxia and falls since the age of 30. The family history revealed three affected relatives: a sister with cerebellar ataxia and peripheral neuropathy, a maternal cousin with early-onset parkinsonism, and a maternal uncle diagnosed with spinal muscular atrophy. Neurological examination showed asymmetric tetraparesis with muscle atrophy, predominantly in the lower limbs, associated with global areflexia, bradykinesia, muscle rigidity with cogwheeling, resting tremor (right hand), postural instability, and cerebellar gait ataxia. Extensive work-up revealed increased CSF protein, EMG signs of peripheral axonal motor neuropathy, muscle biopsy findings of denervation, and peripheral nerve biopsy showing hypertrophic neuritis. Brain and spinal cord MRI were normal. Tests for FRDA (Friedreich's ataxia), EAOH, SCAR1 (ataxia and ocular apraxia types 1 and 2), POLG, SCA (types 1, 2, 3, 6, 7, 8, 10, 12, 14, and 17), PARK2, and SMN1 genes were negative. Whole-exome sequencing demonstrated the presence of a homozygous mutation in the DNAJB2 gene (DNAJ/HSP40 homolog, subfamily B, member) (Chr2: 220.146.784, Variant: c.352+1G>A (IVS5+1G>A)). The same homozygous DNAJB2 mutation has been associated with a rare lower motor neuron disease, characterized by distal hereditary motor neuropathy, previously described in a Jewish family from Morocco. Gess et al. have shown that other DNAJB2 mutations are the cause of Charcot-Marie-Tooth disease type 2 (CMT2). In this Brazilian case report, we describe a new phenotype of this disease, which includes movement disorders, parkinsonism, and cerebellar ataxia.

Distinct patterns of CNS damage along the spectrum of ATXN2-related disorders

Paulo Schneider Wolmer[1], Fabricio Castro de Borba[1], Thiago Junqueira Ribeiro de Rezende[1], Marcondes Cavalcante França Junior[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Paulo Schneider Wolmer; Email: paulowolmer@gmail.com.

Background: ATXN2 is located on cromossome 12 and encodes the transcription factor ataxin-2. There is a polymorphic CAG-rich region within ATXN2 coding region that encodes a polyglutamine tract in ataxin-2. The normal (CAG) length is <27 repeats. When the CAG repeat falls between 27 - 34 repeats, it is a proven risk factor for ALS (ALS-ATXN2); and when it presents with >34 repeats, it causes spinocerebellar ataxia type 2 (SCA2). The huge phenotypic differences between these 2 allelic conditions related to ATXN2 is not yet understood. **Objective:** To characterize and compare central nervous system structural signature in ALS-ATXN2, SCA2, sporadic ALS (sALS) and matched controls. **Methods:** To accomplish that, we first selected four age-and-sex matched groups: controls (n=34), sALS (n=17), ALS-ATXN2 (n=16) and SCA2 (n=17). Then we used automated segmentation tools to calculate the volumes of different CNS structures from T1-weighted MRI images of the patients: FastSurfer for cerebral cortex, deep brain nuclei and brainstem; CerebNet for cerebellum; and SCT (SpinalCord Toolbox) for the cross-sectional area of the first 4 cervical spinal cord levels. And lastly, we compared the mean volumes and areas of the structures between the groups. **Results:** In comparison to healthy controls, we found that: (1) sALS group presented only bilateral precentral gyrus thinning; (2) ATXN2-ALS group presented cervical spinal cord, medulla and midbrain atrophy; and (3) SCA2 presented spinal cord, the whole brainstem (medulla, pons, midbrain and superior cerebellar peduncle), the whole cerebellum (both white and grey matter structures) and deep brain nuclei (thalamus, caudate, putamen, pallidum, hippocampus, amygdala, accumbens area and ventral diencephalon) atrophy as well as cerebral cortex thinning (precentral, bilaterally; paracentral and parsopercularis in the left hemisphere and superior temporal gyrus in the right hemisphere). Direct comparison between sALS and ATXN2-ALS groups revealed no significant difference. All the significant results presented an FDR-adjusted p-value < 0.05 and effect-size >0.6. **Conclusion:** We have shown that (1) sALS, ATXN2-ALS and SCA2 have different structural CNS signatures; (2) ATXN2-ALS is characterized by predominant brainstem and spinal cord damage with relative cortical sparing; (3) in ATXN2-related disorders, the length of the repeat expansion drives the pattern of CNS abnormalities. Additional studies should be made to understand the biological bases of such structural differences.

Distribution of antiepileptic drugs by specialized component of pharmaceutical assistance (ceaf): a time series analysis

Lucas Abreu Dias[1], Pedro Henrique de Vilhena[1], Alisson Rafael de Oliveira Pereira[1], Gabriel Augusto Nava Taveira[1]

[1]Universidade Federal de Lavras, Lavras MG, Brazil.

Correspondence: Pedro Henrique de Vilhena; Email: phdvilhena@gmail.com.

Background: Most of the hard outcomes in epilepsy can be avoided by controlling seizures with the continued use of antiepileptic drugs (AEDs). Some of these medications are distributed through the Specialized Component of Pharmaceutical Assistance (CEAF). Most states currently offer 8 drugs for the treatment of epilepsy: Primidone (PRM), Clobazam (CLB), Vigabatrin (VGB), Ethosuximide (ESM), Gabapentin (GBP), Lamotrigine (LTG), Topiramate (TPM) and Levetiracetam (LEV). **Objective:** To analyze the distribution of AEDs made available by CEAF and identify drugs with the highest tendency to be prescribed for each type of crisis. **Methods:** A retrospective study was conducted using data recorded in the SIA available by DATASUS regarding AEDs distributed by the CEAF since its creation in 2009. The analysis was performed using regression for each drug according to the subdivision into groups for the best indication of each AED: Drugs with action on generalized crises (LGT and PMS), focal (GBP and LEV), absence (ESM), and refractory (PRM, CBZ, GBV). **Results:** Over the 14 years of CEAF activity, the most distributed AED was LTG (33%), followed by GBP (30%), and TPM (23%). Except for VGB (APC: -20.6; CI95%: -32.6 to -7.2; p<0.005), all drugs showed an increasing distribution trend at the end of the study period. Although LEV was identified as the AED with the highest trend, more samples are needed to achieve statistical significance (APC: 729%; p=0.15). Considering the groups, LTG was the main choice for generalized crises (60%), with a change in trend in 2017 (APC 14.2; 95%CI: 10.6 to 25.7; p<0.001). ESM was the only drug evaluated in the absence group, with a trend change in 2012 (APC:

15; 95%CI: 10.6 to 19.5; p<0.001). Although LTG also has an effect on this type of crisis, it was placed in the group of generalized crises because of its higher prevalence. In the focal seizure group, the most widely distributed drug was GBP, with two points of change: 2012 (APC: 51.7; 95%CI 42.7 to 66.5; p<0.001) and 2016 (APC 19.4; CI95%: 14.8 to 23; p<0.001). It is important to highlight that LEV was included in the program only in 2016, and that GBP has a wide distribution because it is also effective in the treatment of neuropathic pain. In the refractoriness group, VGB and PRM maintained their stationery trends, whereas CBZ was the most distributed drug, with trend modification in 2012 (APC: 15.8; 95%CI: 12.5 to 18.1; p<0.001), although it is important to note that CBZ is also prescribed as a pure anxiolytic. **Conclusion:** Although there is an overlap of drug indications in the context of type of epilepsy, when separating groups according to their main indication, we found that LTG is the most distributed AED. LTG was also the most frequent option for generalized seizures, while ESM was the most prescribed for absence seizures, GBP among AEDs for focal seizures, and CBZ in the refractoriness group. Except for VGB, all the drugs showed an increasing distribution trend.

DNMT1 mutation cerebellar ataxia in rare expression in a Brazilian family: a report of 2 cases

Emanuelle Campos Amaral[1], Danilo Lemes Reis[1], David Franca Ferreira Cruz[1], Maria Esther Lima Rios Evangelista[2], Fernanda Almeida Carvalho[1], Manuela Brandao Ferreira Teles[1], Eduarda Kei-lan Tavares Pierre[1], Diogo Rabelo de Lima[1], Fernando Luiz Westphal Filho[2], Marcus Vinicius Della Coletta[1]

[1]Universidade do Estado do Amazonas, Manaus AM, Brazil.
[2]Universidade Federal do Amazonas, Manaus AM, Brazil.

Correspondence: Emanuelle Campos Amaral; Email: eca.med22@uea.edu.br.

Case presentation: M.L.M.S., a 59-year-old female, Italian descendent, hypertensive and diabetic, has been under neurological care for 12 years. 5 years ago, A positive genetic test revealed a heterozygous mutation in exon 21 of the DNMT1 gene (NM_001130823.1:c.1709C>T [p.Ala570Val]). She clinically presents with cerebellar ataxia, deafness, and narcolepsy. Magnetic resonance imaging shows a T2 hypointense signal in the globus pallidus bilaterally, as well as in the gray matter nuclei of the midbrain, and diffuse brain atrophy. Polysomnography demonstrates a multiple sleep latency test with a sleep onset time of less than 8 minutes, associated with 3 sleep-onset REM periods. On physical examination, she exhibited Babinski sign and bradykinesia on the left side, postural and resting tremor (predominantly on the left), and hyperactive deep tendon reflexes (+++/4). N.M., a 63-year-old male, italian descendent, diabetic, with a positive genetic test confirming a heterozygous mutation in the DNMT1 gene (NM_001130823.3:c.1709C>T [p.Ala570Val]). He underwent testing following the diagnosis of his sister, M.L.M.S. He has a similar clinical presentation, with deafness, narcolepsy, and cognitive impairment. Magnetic resonance imaging revealed no abnormalities. **Discussion:** DNMT1 is a widely expressed DNA methyltransferase maintaining methylation patterns in development, and mediating transcriptional repression by direct binding to HDAC. Despite international reports of de novo mutations, in Brazil there is only one report on the mutation that occurs in this patient. Cerebellar ataxia associated with deafness and narcolepsy has an autosomal dominant genetic character and a hereditary inheritance pattern. When with the Ala570Val mutation, it has late symptomatic expression (between 30 and 40 years), with dementia associated with the final process of pathological development. Associated with the same clinical picture, there are the Val606Phe and Gly605Ala variants, where the first has earlier symptoms. Regarding the patient's genealogy, only the cases presented have a positive genetic test, the other family members, even with deafness or movement disorders, tested negative for the variant. Furthermore, one M.L.M.S patient was using carbamazepine 200mg, prolopa HBS 100/25 and fluoxetine 20mg with the aim of reducing symptoms. **Final comments:** Given the above, the impact of genetic variation on the development of the disease is clear, as well as the existence of its hereditary pattern and its impact on human development. Furthermore, the need to establish a correct diagnosis is evident to define an objective prognosis and ensure the individual's minimum well-being.

Do not neglect sudden paresthesia: a case report of cheiro-oral syndrome

Samia Talise El Horr de Moraes[1], Camila Emi Fujiwara Murakami[1], Caroline Link[1], Valmir Vicente Filho[1], Carolina Mibielli de Souza[1], Catarina Dantas Corrêa[1], Isabelle Pastor Bandeira[1], Cesar Minoru Toita Koga[1], Alana Bacelar Limeira Sales[1], Caio Cesar Diniz Disserol[1]

[1]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Alana Bacelar Limeira Sales; Email: alanabls@hotmail.com.

A 59 years old man was admitted in a stroke protocol with a history of sudden paresthesia in the left upper and lower lips and ipsilateral upper limb, as well as dysarthria. He had a previous medical history of hypertension, diabetes, and dyslipidemia. At admission, his vital signs were stable, and no other abnormality in the physical exam was identified. Head CT was performed and showed a small hyperdensity of less than 1 milliliter in the right thalamus. He had not been taking his medications for 40 days before the admission. Thus, after head and neck CT angiography and brain MRI with no suspicion of another etiology, it was concluded that it was an intracerebral hemorrhage due to uncontrolled hypertension. This case excels in exemplifying the commonly neglected cheiro-oral syndrome (COS), which is considered a pure sensory thalamic lacunar syndrome with symptoms that affect the face, hand and/or foot. Although classically associated with thalamic ischemic lesions, there are descriptions of hemorrhagic strokes and multiple different affected regions, including the brainstem, internal capsule, operculum, cortex, corona radiata and thalamus. Whilst a mild clinical stroke presentation with potential misleading diagnosis, early recognition and diagnosis is essential to institute adequate early treatment and secondary prophylaxis. Physicians should be aware of COS and consider a low threshold for investigation, considering the potential severity of its etiologies.

Do Parkinson's disease subtypes impact an individual's ability during the functional task of boarding a bus?

Renan Alexandre Mregalote[1], Eveline Gonçalves Maki[1], Andressa Leticia Miri[1], Patrícia Gonçalves Broto[1], Amanda Lima Nogueira dos Anjos[1], Guilherme Lopes Barbosa da Silva[1], Larissa Laskovski[1], Suhaila Mahmoud Smaili[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.

Correspondence: Eveline Gonçalves Maki; Email: eveline.goncalves@uel.br.

Background: Parkinson's disease (PD) is a neurodegenerative, chronic, and progressive condition. Its clinical spectrum is broad, with both motor and non-motor symptoms affecting the functional independence of the population that suffers from it. Due to the heterogeneous nature of its symptoms, classifying PD into subtypes based on predominant symptoms may help understand if (and how) these subtypes impact the performance of functional tasks and locomotion, such as boarding a bus. **Objective:** To compare and assess the correlation between upper limb strength and ground reaction force during the task of boarding a bus prototype, as well as to investigate the impact of cognition and the fear of falling during the task, according to the PD clinical subtypes. **Methods:** A cross-sectional study involving 30 individuals with idiopathic PD divided into the rigid-akinetic (RA: n=19) and tremor-dominant (TD: n=11) subgroups, based on the Unified Parkinson's Disease Rating Scale. These individuals underwent cognitive assessment using the Mini-Mental State Examination, fear of falling assessment using the Falls Efficacy Scale-International, grip and pull strength analysis using dynamometry, ground reaction force analysis using a force platform, and the time taken to board a bus, both in single-task (ST) and dual-task (DT) conditions. A comparative analysis between disease subtypes and a correlation analysis between variables were conducted, with significance set at p<0.05. The study was approved by the Research Ethics Committee (CAAE: 23272819.8.0000.5231). **Results:** There were no significant differences in the clinical characteristics and the variables analyzed for boarding the bus between the RA and TD subgroups. Correlation analysis revealed correlations between cognitive function and grip strength during ST (rho=0.759; p<0.001) and DT (rho=0.707; p=0.001), as well as pull strength during ST (rho=0.691; p=0.001) and DT (rho=0.703; p=0.001). Additionally, correlations were found between having the fear of falling and the time taken to board the bus during ST (rho=0.662; p=0.002) and DT (rho=0.606; p=0.006), as well as maximum grip strength (r=-0.475; p=0.04) and maximum pull strength (r=-0.479; p=0.038). **Conclusion:** There were no differences between PD clinical subtypes in performing the task of boarding a bus. The findings revealed that worse cognitive function was associated with poorer upper limb strength, particularly in the RA subtype. Furthermore, greater fear of falling was associated with lower maximum upper limb strength and longer boarding task execution time. These findings underscore the importance of considering not only motor manifestations but also cognitive factors in performing functional tasks, regardless of PD subtype.

Do sleep distubances impact the qualrity of life and cognition similarly in men and women with Parkinson's disease?

Rogério José de Souza[1], Amanda dos Santos Siqueira[1], Luísa Vigiani Cassiano[1], Nathalia de Oliveira Franco[1], Suhaila Mahmoud Smaili[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.

Correspondence: Rogério José de Souza; Email: rogerio.jose.souza@uel.br.

Background: Much research has been conducted on the influence of sex-related differences on Parkinson's disease (PD). While men are approximately 1.5 to 2 times more likely to develop the disease and exhibit more tremors, rigidity, cognitive decline, and autonomic dysfunctions, women report more postural instability, depression, anxiety, and pain. Despite sleep disturbances being very prevalent in patients with PD, little is known about the differences when it comes to the quality of sleep experienced between men and women and the impact of the differences if any on their quality of life and cognition. **Objective:** To compare the quality of sleep between men and women with PD and to assess its correlation with the

quality of life and cognition according to sex-related differences. **Methods:** This is a cross-sectional study composed of 73 individuals (50 men and 23 women) diagnosed with idiopathic PD, at a mild to moderate stage, and without cognitive deficits. Quality of sleep was assessed using the Parkinson's Disease Sleep Scale (PDSS-2), the Pittsburgh Quality of sleep Index (PSQI), and the Epworth Sleepiness Scale (ESS). Individuals scoring above 5 on the PSQI were classified as having "poor sleep." Cognition and quality of life were evaluated using the Montreal Cognitive Assessment (MoCA) and the Parkinson's Disease Quality of Life Scale (PDQ-39), respectively. A significance level of 5% was adopted for the analyses. The study was approved by the Research Ethics Committee (CAAE: 54383021.8.0000.5231). **Results:** Regarding sleep classification, 72% of men and 52.2% of women were classified as having poor sleep quality. There was no difference in the total scores of the sleep scales between men and women. The only difference detected was that men had worse scores in the daytime dysfunction domain of the PSQI (p=0.015). In the correlation analysis between sleep and quality of life, there was a moderate correlation between the total PDSS-2 and PDQ-39 in both groups (Men: r=0.66; p< 0.001 - Women: r=0.61; p=0.002), and between the PSQI and PDQ-39 only in men (r=0.46; p=0.001). Concerning daytime sleepiness and the quality of life, there was a moderate correlation between the ESS and PDQ-39 in women (r=0.51; p=0.013) and a weak correlation in men (r=0.37; p=0.007). Regarding cognition, a moderate correlation was observed between the total PDSS-2 and the naming domain of the MoCA in men (r=-0.47; p<0.001) and the total PSQI with the abstraction domain in women (r=0.64; p=0.001). **Conclusion:** In this study, a difference was observed in the daytime dysfunction domain, with men scoring worse compared to women, indicating the impact of sleep on daily functionality. Additionally, men and women with better quality of sleep exhibited signs of a better quality of life. Finally, regarding cognition, men with better quality sleep performed better in the naming domain, while women with better quality sleep performed better in the abstraction domain.

Does antidepressant use interfere with multiple sclerosis patient's outcome?

Mariana Martins Dantas Santos[1], Renata lameira Oliveira[2], Paulo Matheus Casal de Souza[2], Cintia Ramari[3], Carlos Bernardo Tauil[4]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.
[2]Escola Superior de Ciências da Saúde, Brasília DF, Brazil.
[3]University of Hasselt, Faculty of Rehabilitation Sciences, REVAL, Belgium.
[4]Universidade de Brasília, Brasília DF, Brazil.

Correspondence: Mariana Martins Dantas Santos; Email: marianadantassantos@gmail.com.

Background: Depression is commonly associated with multiple sclerosis (MS), affecting between 15-50% of these patients. This co occurrence highlights a potential shared pathophysiology between these two conditions, characterized by inflammatory processes, structural abnormalities, and functional and genetic impairs. Recently, the correlation between depression and MS has gained increased significance, with emerging research indicating that antidepressant treatments may also potentially enhance disease-modifying effects in MS. Which is shown by a reduction of the frequency of MS flare-ups and the recurrence of symptoms, highlighting an important approach for the management of this disease. **Objective:** To assess the prevalence of MS patients using both disease-modifying therapies (DMTs) and antidepressants, and outcomes of MS patients who use antidepressants and those who do not. **Methods:** Data from 241 individuals using DMTs sourced from the Collaborative Latin American Database for Multiple Sclerosis (BRANDO) was analyzed. Outcomes included marital and employment status, sleep disturbances, sphincter control, sexual dysfunction, Expanded Disability Status Scale (EDSS), Nine Hole Peg Test - NHPT, walking capacity (Timed 25-Foot Walk Test - T25FWT), cognitive processing speed (Symbol Digit Modality Test - SDMT), and fatigue (Modified Fatigue Impact Scale - MFIS). Depression and anxiety were assessed by the Beck Depression and Anxiety Inventory (BDI and BAI) and Hospital Anxiety and Depression Scale (HADS-A and HADS-D). Chi-Square and Independent T-tests compared antidepressant users and non-users. **Results:** Out of the 241 patients, 129 (53%) used both antidepressants and DMTs. Data analysis revealed that these individuals had significantly higher EDSS scores (p=0.03), more prevalent sleep disturbances (p=0.013), and higher fatigue levels (MFIS) (p<0.001) compared to non-users of antidepressants. No significant differences were found in demographic outcomes or motor and cognitive functions. Depressive symptoms were significantly higher in the antidepressant user group. **Conclusion:** While recent studies suggest that antidepressants may have a beneficial effect on MS symptoms, our sample revealed that MS patients using antidepressants presented greater disability. However, this analysis could be biased by issues such as the characteristics of the population, potential side effects of these medications, and the timing of evaluations. Therefore, given the frequent co-occurrence of MS and depression, it is crucial to survey the long-term outcomes of these patients. Considering this, longitudinal studies should be performed.

Does COVID-19 impact the modulation of the cardiac autonomic nervous system in patients with systemic arterial hypertension?

Pedro Igor Lustosa Roriz[1], Heitor Fernandes Silveira Cavalini[1], Ádrya Aryelle Ferreira[1], Camila Almeida Sá[1], Joice de Souza Batista[1], Matheus Sobral Silveira[1], Edelvita Fernanda Duarte Cunha[1], Leandro Campos de Brito[2] , Victor Ribeiro Neves[1]

[1]Universidade de Pernambuco, Petrolina PE, Brazil.
[2]Oregon Health & Science University, Portland, OR, USA.

Correspondence: Pedro Igor Lustosa Roriz; Email: pedroilroriz@gmail.com.

Background: Systemic arterial hypertension (SAH) when associated with COVID-19 increases the risk of morbidity and mortality. Heart rate variability (HRV) is considered an important predictor of clinical outcomes. An adequate HRV reflects good integrity of the autonomic nervous system. **Objective:** To evaluate the cardiac autonomic nervous system through HRV in hypertensive patients infected or not with COVID-19. **Methods:** This is an observational and cross-sectional study. Hypertensive patients, over 18 years of age, of both sexes, with or without a diagnosis of COVID-19 were included and grouped into: Group 1 (G1) - hypertensive patients diagnosed with COVID-19; and Group 2 (G2) - hypertensive patients without a diagnosis of COVID-19. All participants underwent a resting electrocardiogram. Recording of electrocardiogram RR intervals was performed in the supine position for 10 minutes. The time series of 256 points with greater stability was used to obtain HRV indices, acquired using linear (time and frequency domain) and non-linear (Symbolic and Entropy analysis) methods. Thirty-three patients were included in the study. **Results:** G1 was predominantly composed of white individuals (47.1%), male individuals (58.8%), sedentary (58.8%) and without associated diseases (52.9%). G2 was predominantly composed of black individuals (50%), male individuals (50%), sedentary individuals (62.5%) and patients with associated diseases (56.2%), especially diabetes and osteoarthritis. There was no statistical difference between the groups for these variables. Regarding the symptoms presented by hypertensive patients with COVID-19, we highlight headache, fever, cough, runny nose and dyspnea, which affected more than 30% of patients in G1. Regarding HRV indices in the supine position, there was no statistical difference between the groups. **Conclusion:** According to the data presented, it is suggested that COVID-19 does not affect the modulation of the cardiac autonomic neural system in hypertensive patients who presented mild symptoms of the disease.

Background: Ginkgo Biloba (EGb) leaf was used in treating cerebrovascular diseases due to its neuroprotective effects in Chinese Traditional Medicine. However, the potential benefits of Ginkgo Biloba extracts (GBE) in patients with moderate to low acute ischemic stroke (AIS) are still controversial. **Objective:** Therefore, we aimed to conduct an updated meta-analysis to compare GBE to other pharmacological interventions in stroke therapy. **Methods:** We systematically searched PubMed, Embase, and Cochrane for randomized clinical trials comparing GBE to placebo or standard treatment. The primary outcome of interest was functional outcome based on mRS 0-1 scale. Secondary outcomes were: functional outcome based on mRS 0-2 scale, change on MoCA total score and all-cause mortality. Comparative analysis with odds ratio (RR) and mean difference (MD) with 95% confidence intervals (CI) were used, and p-value <0.05 was considered significant. **Results:** Six randomized controlled trials (RCTs) comprising 8361 patients were included in this meta-analysis. Three RCTs, encompassing 4,840 patients, reported data for excellent functional outcome (mRS 0-1). GBE was associated with an improvement in functional outcomes compared to the control group, with a low heterogeneity in the results (RR: 1.17; 95% CI 1.11-1.24; p<0.001; I^2=0%). Regarding cognitive outcome, MoCA total score was reported by three studies involving 3,698 patients. MoCA total score was overall higher in the experimental group after GBE therapy (MD: 0.77; 95% CI 0.12-1.42; p=0.02; I^2=54%). All-cause mortality was reported by three studies, including 4,837 patients. GBE did not improve mortality rate compared to the control group (RR: 0.63; 95% CI 0.09-4.52; p>0.05; I^2=85%). **Conclusion:** GBE significantly improved post-AIS functional and cognitive outcomes based on mRS 0-1 scale and MoCA total

score, respectively, with no significant impact on overall mortality in these patients. In summary, our findings suggest that GBE alone has a positive impact in patients with AIS with low NIHSS. Larger randomized controlled trials outside of China are needed to adequately assess the efficacy and safety of GBE for AIS in different populations with bigger sample sizes.

Correspondence: Leonardo Cruz de Souza; Email: leocruzsouza@hotmail.com.

Background: The distinction between progressive supranuclear palsy (PSP) and behavioural variant frontotemporal dementia (bvFTD) is a clinical challenge, due to overlapping clinical, cognitive and behavioural features. Midbrain atrophy is observed in PSP, but the diagnostic value of patterns of midbrain atrophy to differentiate bvFTD from PSP has not been explored so far. **Objective:** To investigate whether quantitative and qualitative measures of midbrain atrophy contribute to the clinical differentiation between PSP and FTD. **Methods:** We included the following groups of participants: healthy controls (n=19; 6 male/13 female; mean age=63.1 years-old), PSP-Richardson' syndrome (n=20; 10 male/10 female; mean age=67.6 years-old), bvFTD (n=19; 11 male/8 female; mean age=66.5 years-old) and Parkinson's disease (PD; n=12; 7 male/5 female; mean age=61.9 years-old). Participants underwent 3T brain MRI. Quantitative and qualitative measures (Hummingbird sign rating scale [HBS-RS], global midbrain atrophy [GMA] and midbrain to pons ratio) were calculated with Radiante software. Brainstem measures were extracted with FreeSurfer. Raters were blind to the clinical diagnosis. **Results:** Groups did not differ in terms of age and sex distribution. Disease duration did not differ between PSP and bvFTD patients. Compared to controls, PSP and bvFTD had lower HBS-RS and GMA scores. Patients with PSP had significantly lower midbrain measures than PD. The HBS-RS, the GMA, the midbrain/pons ratio and the brainstem volumes distinguished PSP from FTD with 73%, 67%, 75% and 82% accuracies, respectively. Imaging measures did not correlate with clinical parameters within groups. **Conclusion:** In this multimodal neuroimaging investigation, both quantitative and qualitative measures of midbrain atrophy provided modest accuracy to distinguish PSP from FTD, thus reinforcing the complex interface between both diseases.

Background: Drop attacks represent a severe expression of epilepsy, with frequent sudden falls, leading to significant injuries and morbidity. Such seizures are thought to arise from sudden bilateral motor cortex synchronization. One strategy for such seizures is to section the callosal fibers in an attempt to render synchronized discharges. A recently new surgical strategy is to section the posterior half of the corpus callosum, therefore sparing frontal fibers. However, no study has analyzed if section of the posterior corpus callosum indeed leads to diminished secondary synchronization. **Objective:** To study the rate of epileptic discharges and, especially, bilateral secondary synchronization. **Methods:** From 2014 to 2018, 12 patients with refractory epilepsy who underwent Posterior callosotomy at the Porto Alegre Epilepsy Surgery Program were analyzed. All had been previously discussed in a multidisciplinary conference and underwent high resolution MRI and prolonged Video-EEG (pre and post-callosotomy). Post-surgical Video-EEG lasted for at least 24 hours. We analyzed pre and post-callosotomy EEG according to the following variables: frequency of number/rate of synchronized discharges in 24 hours, regionalization of discharges, morphology of discharges, as well as frequency and morphology of electrographic and clinical seizures. In addition, we analyzed changes in the background rhythms. **Results:** Mean age at surgery was 18.8 ± 12.2 years and eight patients were female. Secondary bilateral synchrony (SBS) decreased from 2122±3.897.75 to 2±298.75 (p=0.002; Wilcoxon). Generalized EEG seizures significantly reduced post-surgically (62±177 x 1±7.5; p=0.002, Wilcoxon). Tonic seizures during sleep and rate of burst suppression also decreased (p=0.01 and 0.028, respectively). There was no significant change in relation to localization of discharges, morphology or background rhythms. **Conclusion:** Posterior callosotomy is a highly effective surgical treatment for drop attacks and greatly improves electroencephalographic patterns post-surgically. As demonstrated by our study, post-surgical EEG showed significantly less synchronized discharges and generalized EEG seizures. Further studies may analyze if such changes in epileptogenicity lead to improve cognition and a switch from pathogenic to healthy networks dynamics.

Correspondence: Sara Garcia Amaro dos Reis; Email: saragarcia.reis13@gmail.com.

Background: Postural instability and gait disturbances are among the most disabling symptoms in Parkinson's disease (PD), leading to a negative impact on quality of life and daily activities, with a significant increase in the risk and occurrence of falls in individuals with PD. **Objective:** To correlate postural control with kinematic parameters of gait in individuals with PD. **Methods:** This is a cross-sectional study, including 24 individuals diagnosed with idiopathic PD, in mild to moderate stages, without cognitive deficits, and attending a specialized neurofunctional physiotherapy outpatient clinic. Kinematic gait assessment was performed using a 3D motion analysis system (Optitrack), under conditions of single-task and dual-task gait. The parameters analyzed in one gait cycle were: step length and width, cadence, maximum and minimum ankle angles, vertical and medio-lateral center of mass amplitude, and gait speed. Postural control was assessed using the Mini Balance Evaluation Systems Test (Mini-BESTest). Correlations between the variables obtained in the kinematic assessment and the Mini-BESTest were analyzed. The significance level adopted was 5%. The study was approved by the Research Ethics Committee (CAAE: 72474923.3.0000.5231). **Results:** Moderate correlations were found between the total Mini-BESTest score and the variables of normal gait: step length 1 (r=0.41; p=0.04), step length 2 (r=0.42; p=0.03), and average speed (r=0.41; p=0.04), as well as the variables of dual-task gait: step length 1 (r=0.41; p=0.04) and maximum ankle amplitude (r=0.45; p=0.02). Detailed analysis by domains of the Mini-BESTest revealed a moderate correlation of the "anticipatory adjustments" domain with step width 1 in normal gait (r=-0.53; p<0.01). For the "reactive postural control" domain, there was a moderate correlation with maximum ankle amplitude in normal gait (r=0.54 and p<0.01) and with maximum ankle amplitude in dual-task gait (r=0.45; p=0.02). The "sensory orientation" domain showed a moderate correlation with step length 1 in normal gait (r=0.45; p=0.02) and step length 2 in dual-task gait (r=0.41; p=0.04). Finally, there was a moderate correlation between the "dynamic gait" domain and the variables in normal gait: step length 1 (r=0.47; p=0.02), step length 2 (r=0.42; p=0.03), and minimum ankle amplitude (r=-0.54; p=0.01). **Conclusion:** Individuals with PD with worse postural control presented worse kinematic parameters of gait, especially step length and speed in normal gait, as well as step length and maximum ankle amplitude in dual-task gait. Understanding that postural instability alters gait patterns in individuals with PD assists in the search for effective methods in the rehabilitation of these outcomes.

Does the upper limb strength exerted to board a bus correlate to gait in individuals with Parkinson's disease?

Larissa Floripes de Souza Merética[1], Andressa Leticia Miri[1], Patrícia Gonçalves Broto[1], Hayslenne Andressa Gonçalves de Oliveira Araújo[1], Maria Eduarda Brandão Bueno[1], Guilherme Lopes Barbosa da Silva[1], Larissa Laskovski[1], Suhaila Mahmoud Smaili[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.

Correspondence: Larissa Laskovski Dal Molin; Email: larilask@gmail.com.

Background: Parkinson's disease (PD) is characterized by motor symptoms that affect mobility, transfers, balance, gait, and posture. Gait, in particular, is marked by increased cadence, reduced speed, shorter steps and stride length, a longer double support phase, and asymmetry of the upper and lower limbs. In patients with PD, the upper limb functionality is impaired by reduced muscle strength, altered manual dexterity, and deficits in motor coordination during bimanual activities. These dysfunctions limit functional mobility and result in restrictions when it comes to social participation as well as difficulties in performing daily tasks. Public transportation plays a significant role in urban mobility, and thus adequate infrastructure to ensure better accessibility and safety is crucial so as to avoid socially excluding this population. **Objective:** To correlate upper limb strength during the functional task of boarding a bus to gait in individuals with PD. **Methods:** This cross-sectional study included 24 participants. Data on disease staging and progression was collected using the Hoehn & Yahr and the Unified Parkinson's Disease

Rating Scales, respectively. Additionally, the following were administered: 1) a semi-structured questionnaire with clinical, sociodemographic, anthropometric questions and the frequency in which public transportation is used; 2) a cognitive state assessment using the Mini-Mental State Examination; 3) a fear of falling assessment using the Falls Efficacy Scale; 4) an upper limb grip and pull strength evaluated using two dynamometers attached to the handrails of a prototype bus similar to those used in the city of Londrina, Parana, measuring variables like maximum voluntary contraction, grip, and pull strength; and 5) a kinematic gait evaluation using a 3D motion analysis system, collecting variables such as step length, step width, cadence, and gait speed. Data analysis involved Pearson correlation testing with statistical significance set at $p<0.05$. The study was approved by the Research Ethics Committee (CAAE: 23272819.8.0000.5231). **Results:** A moderate and statistically significant correlation was observed between the maximum voluntary left-hand grip strength and the step length ($p\leq0.011$; $r=0.511$). In the functional task of boarding the bus, there was a moderate and significant correlation between the left-hand's grip strength and gait cadence ($p=0.009$; $r=0.523$) as well as between the right-hand's pull strength and the step width ($p=0.040$; $r=0.422$). **Conclusion:** The greater the maximum left-hand grip strength, the longer the step length and the higher the gait cadence. This result brings research closer to clinical practice, highlighting the importance of a thorough evaluation and upper limb training to ensure greater independence for individuals with PD.

Don't close your eyes for this diagnosis: prevalence and characteristics of Jeavons' syndrome in an epilepsy monitoring unit in Southern Brazil

Leticia Bassani Devens[1], Glauco Kody Nagata[1], Pedro Simões dos Santos Pilau[2], Andressa de Oliveira Felício[2], Maria Paula de Carli Hanel[2], Stella Duarte Pinto[2], Natália Balbinot Zanin[2], Helena Pacheco Helms[2], William Alves Martins[1]

Background: Jeavons' syndrome (JS) or epilepsy with eyelid myoclonia is one of the most distinct generalized idiopathic epilepsies, corresponding to 7.9 to 12.3% of genetic epilepsies with predominant early age onset and affecting women more. Typically, this syndrome is manifested by a triad of myoclonia with or without absence, eye closure elicited paroxysms in the EEG and photosensitivity. Regarding semiological findings, the eyelid myoclonus occurs several times a day, mainly after eye closure. Patients also commonly experience generalized tonic-clonic seizures and myoclonus. Furthermore, intense blinking may elicit epileptic focus and can be useful for diagnostic ends. Finally, valproic acid and levetiracetam stand out among the medications for the seizure control. **Objective:** To analyze different presentations of patients diagnosed with JS in the epilepsy monitoring unit (EMU) in Hospital São Lucas da Pontifícia Universidade Católica do Rio Grande do Sul, as well as provide a brief literature review of the subject. **Results:** From 2021 to 2024 6 (1.63%) patients out of 367 patients admitted to the EMU of the Porto Alegre Epilepsy Surgery Program received a final diagnosis of JS. Four (67%) patients were younger than 20, predominantly female (67%). Furthermore, in 16% of cases the seizure onset was within the first 28 days of life, 33% with onset in infants and 50% had their first seizure throughout adolescence. None had a history of febrile seizures. Seizures occurred weekly for 4 (67%) patients and monthly for 2 (33%). Moreover, half the patients with weekly seizures progressed with daily absent seizures. Video-EEG showed generalized maximum posterior spike-wave complexes (33%) and polyspikes (67%) upon eye-closure and photosensitivity (83%), more prominently after medication tapering. Mild intellectual disability was present in 3 (50%) patients. Regarding semiology, 67% of them manifested as generalized bilateral tonic-clonic seizures, with 75% of thsese starting with eyelid myoclonus. The remaining was manifested by myoclonus and absent seizures. For treatment, 50% of patients were on valproic acid combined with lamotrigine and clobazam, while the other half used levetiracetam and clobazam. **Conclusion:** This case-series provides data on JS responsible for a significant share of genetic generalized seizure in the EMU. Understanding JS is crucial for accurate differential diagnosis.

Dopa-responsive cervical dystonia: case report

Lavínia Damacena Perin[1], Lucas Grobério Moulim de Moraes[1], Vinícius Andreata Brandão[1], Jovana Gobbi Marchesi Ciríaco[1]

[1]Universidade Federal do Espírito Santo, Vitória ES, Brazil.

Correspondence: Lavínia Damacena Perin; Email: laviniaperin23@gmail.com.

Case presentation: A 21-year-old patient, with no complications related to childbirth, no previous comorbidities or family history of neurological diseases, started at around 11 years of age with involuntary movements of cephalic torsion to the right, usually associated with emotional stress, using musical instruments or physical exertion. She reported a clinical diagnosis of tics and myofascial pain triggered by anxiety for many years, without improvement with the use of fluoxetine 40mg/day, amitriptyline 25mg/day and carbamazepine 200mg/day. Electroneuromyography showed arrhythmic activity with irregular tonic alternation in the right splenius, levator scapulae, semispinalis and trapezius muscles and in the left sternocleidomastoid and semispinalis muscles. She reported a progressive worsening in the frequency and intensity of the crises and at the age of 20 she began to report intermittent pain and fixed posture, regardless of the triggering factor. Physical examination showed focal dystonia affecting the cervical muscles: right splenium, trapezius and scalene, and to a lesser extent the left semispinal, sternocleidomastoid and trapezius muscles. In view of the early onset of dystonia, a therapeutic trial was carried out with levodopa + benserazide 100/25mg twice a day, with a satisfactory response. Laboratory and neuroimaging tests ruled out iron deposition and copper metabolism diseases. The patient is currently being monitored on an outpatient basis, having already stopped antidepressant and anxiolytic medication. She reports complete improvement in pain and involuntary cervical movements. **Discussion:** In this report, we present the case of a patient with childhood onset cervical dystonia that was misdiagnosed as tics and myofascial pain triggered by anxiety, responsive to levodopa in a therapeutic trial. Cervical dystonia is a disorder characterized by involuntary contractions of the cervical musculature, resulting in abnormal positioning of the head, usually painful. When diagnosed and treated incorrectly, it becomes disabling and affects the person's quality of life. In most cases, the cause is unknown, and symptoms begin between the seventh and eighth decades of life, there is no cure and it requires long-term treatment. However, with the discovery of mutations in specific genes, more than 25 subtypes with distinct clinical manifestations have been mapped. Among them, a rare subtype, whose first symptoms appear in childhood and show a sustained response to levodopa, is DYT5, also known as Dopa-Responsive Cervical Dystonia (DRD). The clinical manifestations begin in childhood or adolescence with focal dystonia, with diurnal fluctuations and marked nocturnal worsening, which can impair sleep. **Final comments:** This case highlights the importance of levodopa testing for patients with childhood onset dystonia, due to its diagnostic and therapeutic potential, allowing patients to evolve with a good quality of life, without motor complications.

Dorsal root ganglia and spinal cord imaging in genetic and acquired sensory neuronopathies

Rafaella do Rosario Tacla[1], Thiago Junqueira Ribeiro de Rezende[1], Paulo Schneider Wolmer[1], Gustavo Moreira Jarola[1], Alberto Rolim Muro Martinez[1], Marcondes Cavalcante França Junior[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Rafaella do Rosario Tacla; Email: taclarafaella@gmail.com.

Background: The etiology of sensory neuronopathies (SN) can be divided into two key groups: acquired and genetic. **Objective:** We designed an MRI-based study to compare volumetry of the dorsal root ganglia (DRG) and structural imaging of the spinal cord (SC) across healthy controls, patients with acquired SN and patients with Friedreich's ataxia (FRDA), the prototypical genetic SN. We also assessed clinical correlates of these imaging parameters. **Methods:** Sixty-two subjects (21 healthy controls, 20 acquired SN patients, and 21 FRDA patients) underwent 3T MRI acquisitions including: Diffusion-weighted imaging and T2WI of the cervical spine as well as PROSET isotropic T2WI of the lumbosacral spine to assess the DRG. Analyses correlating MRI metrics and clinical parameters were performed. Sex, age and body-mass index were used as covariates in between-group comparisons. **Results:** Patients with FRDA, but not acquired SN had widespread (C1-T1) SC atrophy relative to controls. Fractional anisotropy reduction in the dorsal columns was observed in both groups (effect size 1.42 SN group versus 1.58 FRDA group), but spinocerebellar and corticospinal tracts were affected only in FRDA patients. DRG volumes at L3-L5 were smaller in both groups compared to controls. Dorsal column fractional anisotropy at cervical SC correlated with disease severity in both groups (R: -0.6-0.7). A dedicated MRI protocol can capture SC and DRG abnormalities in both genetic and acquired SN. SC damage seems to be more widespread in genetic SN, which may be useful from a diagnostic perspective. The existing correlation between disease severity and SC diffusivity changes suggests MRI may be also relevant to track disease progression. **Conclusion:** Combined MRI-based evaluation of SC and DRG may be a potential (diagnostic and status) biomarker for sensory neuronopathies.

https://doi.org/10.5327/CBN240583

Dosage of botulinum toxin in hemifacial spasm patients: a referral center experience

Fátima de Menezes Dantas[1], Felipe Olobardi Freire[1], Maria Weryca de Souza Belo Silva[1], Alberto Pereira Firmino Filho[1], Agabio Diogenes Pessoa Neto[2], Clécio de Oliveira Godeiro Junior[1], Rodrigo Alencar e Silva[1]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.
[2]Instituto de Ensino e Pesquisa Alberto Santos Dumont, Macaíba RN, Brazil.

Correspondence: Fátima de Menezes Dantas; Email: fatimamenezesdantas@gmail.com.

Background: Hemifacial spasm is a hyperkinetic movement disorder characterized by intermittent, involuntary contractions of muscles innervated by the facial nerve. The treatment of choice for this condition is regular administration of botulinum toxin. **Objective:** To evaluate the dose of botulinum toxin in patients who had been treated for hemifacial spasm over the last 14 years. **Methods:** A retrospective analysis of medical records from patients treated at a referral center from 2010 to 2024 was conducted. Doses (in units) and dates of botulinum toxin injections were collected and organized into 12-week intervals. An equivalence ratio of 5:1 U was adopted between abobotulinumtoxinA 500U and onabotulinumtoxinA 100U, the two formulations used in that service. The variables were subjected to a Mixed Linear Model test and Pearson correlation. The study was approved by the Local Ethics Committee (CAAE: 72821023.2.0000.5292) and all participants signed an informed consent form. **Results:** A total of 151 patients participated in the study. The average initial dose was 21.5 units. The analysis revealed that the dose of botulinum toxin increased 0.046 units per week ($p<0.05$; $r=0.1268$). During the first 3.46 years, this increase was more pronounced. In the long term, there was a slight increase in dose and a trend towards stabilization was observed. **Conclusion:** We concluded that the dose of botulinum toxin increases more pronouncedly during the initial years of administration, likely due to the need for dosage adjustments until symptom control is achieved with the lowest possible dose. Therefore, it is important to continue treatment even if the initial injections are not completely satisfactory. We believe that periodic and long-term consultations can contribute to achieving an optimized dose for the management of hemifacial spasm. Prospective studies with a larger number of participants may be able to validate these observations, allowing for a better understanding of long-term modifications in botulinum toxin dosage.

https://doi.org/10.5327/CBN240584

Driver's license eligibility in adult patients with epilepsy

Gloria M. A. S. Tedrus[1], Pedro Augusto Silva Prado[1]

[1]Pontifícia Universidade Católica de Campinas, Campinas SP, Brazil.

Correspondence: Gloria M. A. S. Tedrus; Email: gmtedrus@uol.com.br.

Background: Epilepsy can affect occupational and psychosocial aspects, including the eligibility to hold a driver's license. **Objective:** To assess the ownership of a National Driver's License (CNH) among adult patients with epilepsy (PWE) and explore its correlation with clinical variables. **Methods:** The possession of a driver's license was correlated with demographic and clinical data, as well as with the total scores on the Mini-Mental State Examination (MMSE) and the Quality of Life in Epilepsy Inventory-31 (QOLIE-31) among 305 PWE, with a significance level of $p<0.05$. **Results:** The mean age was 49.2 years, with 129 males and 176 females. The mean age at first seizure was 23.5 years, and with a mean of 5.7 years of schooling. Structural epilepsy was present in 203 cases, without an identified etiology in 75 cases, and genetic/generalized in 27 cases. Possession of an CNH (types AB in Brazil [classes M and D in the US] n=26, CDE in Brazil [classes B, C, and A in the US] n=9) was reported by 35 (11.5%) patients. Among those with an CNH, 14 had their first seizure before the age of 18 (Chi-square test, 14/21; $p=0.017$). More male subjects had an CNH (25 vs. 10, $p<0.001$), as well as PWE with no alterations in neurological examination (Fisher's exact test; 31 vs. 4, $p=0.01$) and in patients on a single antiseizure medication (29 vs. 7, $p=0.006$). There was no difference regarding CNH possession according to the type and frequency of seizures and epileptic syndrome. CNH possession was significantly associated with higher educational levels (years) (T-test, 7.5 vs. 5.5, $p=0.004$), better quality of life on the QOLIE-31 (67.0 vs. 59.9, $p=0.008$), and higher scores on the MMSE (25.6 vs. 22.7, $p<0.001$). In PWE with structural epilepsy (n=20), there was a significant difference in CNH type (AB vs. CDE), with fewer cases holding a CDE license (2 vs. 18, $p=0.047$). **Conclusion:** The rate of individuals with an CNH was low. Demographic and clinical aspects were associated with having an CNH, which was associated with better quality of life and better cognitive performance. This sample revealed aspects that are distinct from current legislation, suggesting a lack of information, denial of the disease, or the presence of various associated factors.

Drug candidate prototypes for Parkinson's disease treatment: an in silico, in vitro, and in vivo study

Willian Alves Costa[1], Talita Alves Harrop[1], Gisele Rocha Lopes[1], Bianca Liffey Brito Marino[1], Lorane Izabel da Silva Hage Melim[1], Thiago da Costa Brito[2]

[1]Universidade Federal do Amapá, Macapá AP, Brazil.
[2]Universidade Estadual do Pará, Belém PA, Brazil.

Correspondence: Willian Alves Costa; Email: willianac2021@gmail.com.

Background: Parkinson's disease (PD) is the second most common degenerative disease in the world, especially in individuals over 60 years old. One of the mechanisms used in treatments for PD is monoamine oxidase B (MAO-B) inhibition, an enzyme that degrades dopamine. Recent studies have identified some substances of natural origin with that effect. **Objective:** To design in silico molecules with MAO-B inhibitory activity, based on natural products, carry out the synthesis and test them in vivo. **Methods:** A literature review was conducted to identify natural substances with proven antiparkinsonian activity in vitro and/or in vivo. Subsequently, an in silico study was performed with those substances, including molecular docking studies, prediction of pharmacokinetic and toxicological properties, structural modifications to obtain analogs, and prediction of activity and synthetic feasibility. After obtaining the analogs, synthesis was carried out (in vitro). Finally, for the in vivo study, an acute toxicity test was conducted using a Zebrafish animal model. **Results:** After a literature review, four natural substances were selected for the study: Amburosídeo A, Harman, Harmalina and Harmalol. The drug Selegiline was used as the standard molecule for comparison in the in silico study. In the prediction of pharmacokinetic activities, only the molecule Harman presented satisfactory results. In molecular docking, all substances interacted with more than three amino acids in the active site of MAO-B and some amino acids that Selegiline (the standard molecule) interacted with, suggesting probable inhibitory activity. After the analyses, Amburoside A was selected as the prototype for modifications, and three analogs (PMC1, PMC2, and PMC3) were obtained with results ranging from moderate to good synthetic feasibility. All three analogs showed predicted MAO inhibition activity. Subsequently, the prototypes were synthesized, and the PMC3's was selected for the acute toxicity assay in vivo using a Zebrafish model, due to its potential action on both the MAO-B and COMT enzymes. The test consists of administering the molecule studied at a certain dose to the fish and, if the fish survives for at least 7 days, this indicates a high probability that the substance is not toxic. In this analysis, the results were satisfactory. **Conclusion:** All the planned analogs showed possible MAO-B inhibitory activity in silico. Furthermore, the PMC3 analog also showed action on COMT, an easy synthesis and negative toxicity in the Zebrafish model, revealing a promising multitarget drug for Parkinson's disease treatment. However, more research is still needed to validate these findings and fully explore the safety and efficacy of this molecule.

[2]Universidade de São Paulo, Faculdade de Medicina, São Paulo SP, Brazil.

Correspondence: Lucas do Rego Barros Correa Martins; Email: lucasrbcmartins@gmail.com.

Etiological diagnosis in cases of drug-resistant epilepsy and developmental delays is a daily challenge in clinical practice. This case report presents a 23-year-old male patient referred to the neurogenetics outpatient clinic due to drug-resistant epilepsy, cognitive delay, speech impairment and behavioral changes compatible of autism spectrum since childhood, that was diagnosed as PPP2R5D-related neurodevelopmental disorder. **Case presentation:** The patient has a history of epilepsy since the age of seven, with multiple seizure semiologies (being focal dysperceptive seizures the more prevalent). He was optimally managed with valproic acid and clobazam, maintaining an average frequency of one seizure per month. Additionally, cognitive delay and socialization difficulties since childhood were also reported. Neurological physical examination revealed dental malformations, hypertelorism, and low-set ears, without other alterations, but no ataxia signs were seen. Electroencephalogram revealed clustered sharp waves in the theta frequency in the left temporal region with occasional bilateralization. Brain magnetic resonance imaging showed no abnormalities. The patient underwent analysis through new generation sequencing, where a likely pathogenic variant (c.717T>G; p.Phe239Leu) was identified in the PPP2R5D gene. Other missense mutations in heterozygosity in this gene have been associated with Houge-Janssens Syndrome, with which the presented phenotype was consistent. **Discussion:** Houge-Janssens syndrome is a rare genetic disease caused by mutations in the PPP2R5D gene. This syndrome is characterized by mild to severe neurodevelopmental delay, craniofacial anomalies, hypotonia, speech impairment and autism spectrum disorder. Seizures are reported in fewer than half of individuals. Clinical Interpretation of the variant: The interpretation of variant as clinically relevant is based on the correlation between the clinical picture presented by the patient and the identified genetic alteration. Although not listed in international databases as pathogenic, the presence of specific clinical symptoms strengthens the association between the variant found in the PPP2R5D gene of the patient and Houge-Janssens syndrome. **Final comments:** The identification of the variant in the PPP2R5D gene in our patient provides important diagnostic insights and may guide future clinical management, including specific therapeutic options and genetic counseling for the family. It is crucial to continue investigating and understanding the genetic bases of neurological diseases to provide better care for patients and their families. Rational analysis of findings obtained in genetic tests is crucial for the diagnosis of these complex conditions. Although epilepsy is present in less than 50% of PPP2R5D-related cases, here it was the main clinical issue, which highlights the importance to include this condition in the work-up for drug-resistant epilepsy.

Dual pathology in neurodegenerative dementias: when idiopathic normal pressure hydrocephalus diagnosis masks and modifies other dementias

César Minoru Toita Koga[1], Maria Clara Jorge Jardim[2], Gabriel Abrahão Stoliar[1], Sâmia Talise El Horr de Moraes[1], Alana Bacelar Limeira Sales[1], Alexandre Henrique Scheibe[1], Leonardo Ferreira Caixeta[3]

[1]Universidade Federal do Paraná, Hospital de Clínicas, Curitiba PR, Brazil.
[2]Universidade Federal de Goiás, Goiânia GO, Brazil.
[3]Universidade Federal de Goiás, Hospital das Clínicas, Goiânia GO, Brazil.

Correspondence: César Minoru Toita Koga; Email: cesarmtkoga@gmail.com.

Case presentation: A 66-year-old right-handed woman with 8 years of education presented with progressive gait difficulty, cognitive symptoms, and impaired bladder control. She had a wide-based gait with shuffling steps and impaired working memory. In the next 2 years, her family noted progressive behavioral changes, ranging from irritability with physical aggression to apathy. She also developed preference for sweet foods and began eating compulsively. Cerebrospinal fluid (CSF) analysis and standard dementia laboratory screening were unremarkable. Brain magnetic resonance imaging (MRI) at the time showed extensive communicating hydrocephalus and bilateral frontal and temporal lobes atrophy, predominantly right-sided. At 69 years, she underwent a ventriculoperitoneal (VP) shunt, which resulted only in gait and urinary incontinence improvement. One year later, she exhibited behavioral disinhibition, loss of empathy and theory of mind (ToM), impulsivity, and social inappropriateness. Other symptoms included a persistent false sensation of fibers emerging from her teeth (Morgellons disease) and misidentification syndrome compatible with Frégoli syndrome. There were no visual hallucinations, and insight was absent. Neurological examination revealed the presence of palmomental reflex and inexhaustible glabellar reflex. Cognitive assessment showed predominantly verbal perseverance and frontal lobe dysfunction, with scores of 25/30 on Mini-Mental State Examination, 7 words/minute on Semantic Verbal Fluency test with animals, 12 words on FAS Verbal Fluency test and 5 points in the Clock Drawing Test according to Sunderland criteria. **Discussion:** This case highlights a diagnostic challenge in dementias. Properly diagnosed NPH can mask neurodegenerative dementias, such as behavioral variant frontotemporal dementia (bvFTD). NPH diagnose involves key symptoms (gait disturbance, urinary incontinence and cognitive impairment), typical neuroimaging findings including ventriculomegaly, and symptom improvement after CSF shunting. In our case, NPH presented with its classical triad and imaging findings, leading to VP shunting and motor symptons improvements. However, persistent and progressive behavioral and working memory symptoms post-shunting suggest an underlying bvFTD, or even a dysexecutive variant of Alzheimer's disease. Elements favoring bvFTD include complex neuropsychiatric symptoms (Frégoli and Morgellons syndromes) and significant right hemisphere cortical features such as disinhibition, compulsive behavior, and lack of insight and ToM. These features are atypical for NPH, which primarily causes subcortical dementia. Significant bilateral frontotemporal atrophy on MRI, especially with right-sided asymmetry, also suggests bvFTD. **Final comments:** This case illustrates how overlapping dementia pathologies can complicate each other's diagnosis and management. Careful clinical and neuroimaging assessment is crucial for accurate diagnosis and optimal treatment.

Dural fistula and trigeminal autonomic headache

Cândida Driemeyer[1], Renato Dumbá Monteiro de Castro[1], Liselotte Menke Barea[1]

[1]Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Cândida Driemeyer; Email: candidaplena@gmail.com.

Case presentation: A 62-year-old male patient received the diagnosis of dural fistula, fed by branches of the right external carotid artery and draining into the sigmoid sinus ten years ago when investigating a persistent headache that led him to seek the emergency department. In the last two years, he has been waiting to undergo elective embolization with Interventional Neuroradiology. He has undergone angiotomography which shows that the dural fistula is fed by branches of the right external carotid artery (middle meningeal artery) and a branch originating from the lateral wall of the ipsilateral cavernous segment of the internal carotid artery. The venous drainage occurs through the Labbé vein and the right transverse sinus. He has also undergone angiography, which did not demonstrate additional findings. He was then referred to the Neurology outpatient clinic for a unilateral right headache, pulsatile, which has been present over the last decade but severely worsened over the last two years, becoming disabling. The pain is continuous, but there are periods of exacerbation when moving the head forward. The pain is associated with conjunctival hyperemia and tearing, in addition to rhinorrhea and worsens when moving, and it is not triggered by touch. **Discussion:** Trigeminal Autonomic headaches are highly disabling, and their differential diagnosis is very important for correct management and improvement of the patient's quality of life. In our case, the patient underwent a therapeutic trial with indomethacin and he received a prescreption of valproic acid. He is still awaiting elective intervention on the dural fistula. **Final comments:** Trigeminal autonomic headaches still represent a diagnostic challenge in our setting and always require imaging tests to be performed, so that a secondary etiology can be correctly diagnosed.

Dystonia caused by atp1a3 gene mutation: report of two cases

Vitor Santos de Souza[1], Débora Palma Maia[1], Ricardo Oliveira Horta Maciel[1], Lia Araújo Guabiraba[1], Francisco Eduardo Costa Cardoso[2]

[1]Universidade Federal de Minas Gerais, Hospital das Clínicas, Belo Horizonte MG, Brazil.
[2]Universidade Federal de Minas Gerais, Faculdade de Medicina, Belo Horizonte MG, Brazil.

Correspondence: Vitor Santos de Souza; Email: vitorsantosdesouza@outlook.com.

Case presentation: Case report of twin patients with suspected mutation in the ATP1A3 gene. Patient 1, 39 years old, daughter of non-consanguineous parents, with 2 sisters, one of them dizygotic twin. At the first evaluation in this service in July 2021, previously healthy patient developed sudden choreic movements in the right upper limb (RUL) and neck. Haloperidol and alprazolam were prescribed at a primary health unit. Despite improvement in choreic movements after 30 days of treatment, she developed stiffness in the affected limb, facial and cervical dystonia, gait difficulty, and behavioral changes (childlike behavior), excessive fear, social blunting, and impaired self-care. The neuroleptic was initially switched to risperidone and later to olanzapine, with no satisfactory motor response and worsening psychiatric symptoms and insomnia, leading to a switch to clozapine. On physical examination, there was cervical and trunk dystonia, and RUL dystonia associated with akathisia. The initial diagnosis was tardive dyskinesia (TD) with functional/psychogenic component. With a combination of trihexyphenidyl and clozapine, she remained psychiatrically stable but without improvement in dystonia. In April 2023, deutetrabenazine was prescribed. At this visit, it was reported that her twin sister started experiencing similar symptoms. Patient 2 reported right upper limb pain since 2019. Eight months ago, she started involuntary movements of raising her arm above her head, progressing to abnormal posture of shoulder elevation, internal rotation of the arm, flexion and internal rotation of the forearm, with functional limitation. On examination, there was RUL dystonia - ipsilateral shoulder elevation - with distal tremor, cervical dystonia - laterocollis to the right. The phenomenological pattern strongly suggests a mutation in the ATP1A3 gene. Genetic testing is ongoing, and flunarizine has been initiated. **Discussion:** Mutations in the ATP1A3 gene were initially associated with rapid-onset dystonia-parkinsonism (RDP), typically characterized by abrupt motor onset, sometimes accompanied by non-motor symptoms, mainly psychiatric. Since then, this mutation has been linked to various phenotypes including alternating hemiplegia of childhood and CAPOS (cerebellar ataxia, areflexia, pes cavus, optic atrophy, sensorineural hearing loss). The dystonic pattern in the twin sisters reported here is characteristic of ATP1A3 mutation, as described by Balint et al. There are reports suggesting individuals with this mutation may respond to flunarizine. **Final comments:** The etiological diagnosis of dystonias is often challenging. The patients described here demonstrate that clinical history, family history, and phenomenology remain fundamental tools for diagnosing rare conditions such as ATP1A3-related diseases.

Early and long-term programming characteristics in Parkinson's disease patients submitted to subthalamic deep brain stimulation

Beatriz Azevedo dos Anjos Godke Veiga[1], Cristine Mella Cukiert[1], Rafael Basilio Guimarães[1], Arthur Cukiert[1]

[1]Clinica Cukiert, São Paulo SP, Brazil.

Correspondence: Beatriz Azevedo dos Anjos Godke Veiga; Email: bia-anjos@uol.com.br.

Objective: We aimed to describe the modifications of the subthalamic (STN) deep brain stimulation (DBS) programming parameters in Parkinson's disease (PD) patients in the early and long term. **Background:** PD is a neurodegenerative illness, and DBS has been a well-established efficacious symptomatic treatment for motor symptoms and motor complications. Assessing the best stimulation settings requires numerous clinic visits, and the stimulation intensity has the most significant effect on ameliorating Parkinsonian motor signs in the initial stages of STN-DBS programming. **Methods:** We performed a retrospective analysis of the parameter settings of fifteen patients who underwent STN-DBS with Medtronic devices. The patients were diagnosed with PD according to the UK Brain Bank criteria, and they had a positive result on the levodopa challenge test. We described continuous variables as means ± standard deviations (SD) and categorical variables as percentages. We used Repeated Measure ANOVA to continuous variables z-scores to analyze Levodopa Equivalent Daily Dose (LEDD) and DBS setting variations during six and twelve months after surgery. Scheffe post hoc test was applied, and the p-value considered statistically significant was <0.05. **Results:** Our sample was composed of 15 PD patients with a mean±SD age at PD onset of 48.7±9.0 years, and they took 11±3.7 years to undergo STN-DBS. We evaluated patients an average of 5.3±1.8 times during the first six months post-surgery and 8.6±3.3 times during the first year post-surgery. There was a significant LEDD reduction in six months compared to the pre-surgery (p=0.014) but not from the sixth to the twelfth month. Similarly, considering the variation period but inversely, the parameter amplitude increased only during the first six months (p=0.002). The other parameters, pulse width and frequency, did not statistically change after the first programming session. **Conclusion:** STN-DBS is a powerful symptomatic PD

treatment that requires skilled professionals and intense medical monitoring after neurosurgery to achieve the best results. Nonetheless, the arduous follow-up, including programming parameter variations, happens mainly in the early term.

https://doi.org/10.5327/CBN240590

Early diagnosis of epidermoids cysts in the pontocerebellar angle up to age of 24 years: a challenge for managing neural tube defects - systematic review of the last 20 years

Evelyn Basilio da Silva[1], Rafael Augusto de Souza Santos[1], Anna Beatriz Popi e Souza[1], Ruan Gomez Carvalho Martins[1], Vitoria Rodrigues Carvalho da Silva[1], Milena Alexia Ferreira Cirino[1], Claudio Alberto Ioca Junior[1], Gabriel Borges Peres[1], Carolina Marques Kellner[1], Márcio de Souto Marques Filho[1]

[1]Universidade Nove de Julho, Bauru SP, Brazil.

Correspondence: Evelyn Basilio da Silva; Email: evelyn.basilio@uni9.edu.br.

Background: The neural tube is the origin from the embryo's notochord structure, between the third and fourth week of gestation. During this phase there may be anomalies which affect its proper closure, known as neural tube defects (NTDs). A possible NTD is the development of epidermoid cysts, which grow slowly, occupy space and, in most cases, have late symptoms, frequently occurring in the cerebellopontine angle. Although they are considered congenital defects, these cysts can be recognized at different ages. This singularity raises questions about the possibility of early diagnosis and treatment before changes in the affected individual's quality of life. **Objective:** Analyze the early diagnosis possibility and treatment of epidermoid cysts in the cerebellopontine angle, considering the age range up to 24 years. **Methods:** A systematic review was performed, following the PRISMA check-list, in the SciELO, PubMed and LILACS, using descriptors containing the keywords "epidermoid cyst" and "pontocerebellar angle". Considered those published between the year 2000 and January 2024, which addressed the presence of epidermoid cyst in the mentioned angle, in patients up to 24 years old. **Results:** 412 articles were collected, of which 95 met the criteria. Three main themes emerged from the explanatory content analysis: (1) the prevalence and incidence of epidermoid cysts in the cerebellopontine angle are more frequent in adults and with the potential for greater aggressiveness and worse prognosis in children, with 15 articles; (2) the most frequent symptoms were hearing loss, headache, dizziness and tinnitus, where patients reported that the symptoms persisted for months or even years before medical investigation, with 30 articles and (3) the diagnosis is made through exams imaging, mainly magnetic resonance imaging (MRI) and the most effective treatment continues to be cyst resection, with 40 articles. **Conclusion:** The analysis demonstrated that epidermoid cysts in the cerebellopontine angle can manifest at different ages, with greater aggressiveness in childhood and more frequently in adulthood. Regardless of the period in which they were discovered, these cysts usually affect the full lives of these people with different symptoms, bringing attention to adequate and early clinical investigation. Therefore, late diagnosis can increase the complications risk, including possible loss of neurological function due to its exponential growth around cranial nerves that emerge close to this location. To this end, MRI remains essential for accurate diagnosis, while surgery, with its nuances and risks, remains the most effective treatment of choice. Continuous research into development and progression factors, aiming to improve diagnostic and treatment techniques, is crucial to guarantee the best prognosis and quality of life for patients.

[2]Unichristus, Fortaleza CE, Brazil.
[3]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Antonio Edvan Camelo Filho; Email: edvan.camelo@gmail.com.

Case presentation: A 6-year-old boy was referred for evaluation for abnormal gait and frequent falls since age 3. The motor development was unremarkable until the third year of life, when the family reported the symptoms responsible for the referral. Upon neurological examination, the patient had isolated mild atrophy of the medial compartment of the legs with mild weakness of dorsiflexion. There were no sensitive, cerebellar or cranial nerve deficits. Patient creatine kinase (CK) was within normal limits (135 U/L). The patient performed an electromyographic evaluation that was normal. Due to high clinical suspicion, we evaluated with neuromuscular ultrasound (NMUS), which revealed mild bilateral sartorius and medial gastrocnemius muscle echogenicity changes (Heckmatt scale 2). These findings were suggestive of an early myopathic disorder. Leg MRI confirmed atrophy of the soleus and gastrocnemius muscles. Genetic testing of this patient revealed heterozygous pathogenic variants in MYH7 gene (p.Ala797Thr). Laing myopathy was diagnosed with these clinical, genetic, and radiological findings. **Discussion:** Laing myopathy is an inherited disorder caused by pathogenic variants in MYH7. This gene encodes the myosin heavy chain of type 1 fibers of skeletal muscle and cardiac ventricles, and its deficient expression produces a phenotype of distal myopathy, mostly affecting ankle dorsiflexors and toe extensors, associated with dilated cardiomyopathy. Age of onset is highly variable, reported from congenital to 50 years. However, most patients present signs and symptoms between the second and third year of life. This is a rare form of myopathy, being reported in 2 patients in a large Brazilian cohort of distal myopathies. CK levels are usually normal or only moderately elevated in these patients. Also, some LM patients may have nerve conduction studies reported as normal or even neurogenic. Neuromuscular ultrasound assessment is a trending tool in muscular disorders that may help in making an early diagnosis. In LM the ultrasound assessment may be a quicker and cheaper option to assess the characteristic atrophy of muscles, specially in children and early structural myopathies with normal CK values. **Final comments:** Integrating NMUS with traditional NCS studies enhances diagnostic accuracy, especially in the pediatric population, where EMG findings may initially be unremarkable for mild changes or non-cooperation. Our findings advocate for the wider adoption of NMUS in the diagnostic workup of suspected myopathies, facilitating prompt diagnosis and ultimately contributing to improved patient outcomes through earlier therapeutic intervention. Future research should investigate the potential utility of NMUS in standardized patterns of muscle and nerve assessment and the development of evidence-based protocols for its application in the clinical setting, ultimately improving the quality of life for affected individuals.

Early fecal metabolomic alterations in pilocarpine-induced status epilepticus: insights into tle pathophysiology and resistance mechanisms

Gabriele Fernanda da Conceição Santos[1], Larissa da Silva Almeida[1], Manoela Alves Vieira de Souza[1], Karla Eduarda Silva Ferreira[1], Jeferson Santana Ursulino[1], Thiago Mendonça de Aquino[1], Daniel Leite Góes Gitaí[1]

[1]Universidade Federal de Alagoas, Maceió AL, Brazil.

Correspondence: Larissa da Silva Almeida; Email: larissa.almeida@famed.ufal.br.

Background: Epilepsy, a complex neurological disorder characterized by recurrent seizures, presents a significant health burden worldwide. Among the various types of epilepsy, temporal lobe epilepsy (TLE) stands out for its high prevalence in the adult population. TLE is often associated with alterations in the limbic system (epileptogenesis), typically triggered by epileptogenic insults such as status epilepticus (SE). Understanding its underlying mechanisms is crucial for effective treatment strategies. Recent advances in metabolomics offer a promising avenue for exploring the metabolic alterations associated with epilepsy. By analyzing metabolites, the byproducts of cellular processes, researchers can gain insights into the biochemical changes occurring in epileptic brains. **Objective:** To analyze fecal water metabolites in a Lithium-Pilocarpine-induced status epilepticus (SE) rat model to identify metabolic changes during early epileptogenesis. Specifically, metabolomic analysis will be conducted 24 hours post-SE induction, comparing with SE-resistant and naïve control groups. **Methods:** Male Wistar rats were induced into status epilepticus (SE) using Lithium-Pilocarpine administration and euthanized after 24 hours. Fecal samples were collected and processed for metabolomic analysis using Nuclear Magnetic Resonance (NMR). Three groups were defined: a 24-hour SE group (n=10), an SE-resistant group (n=11), and a naïve group (n=10). Statistical analyses, including T-tests, Principal Component Analysis (PCA), Partial Least Squares Discriminant Analysis (PLS-DA), and Analysis of Variance (ANOVA), were conducted to compare metabolite levels among groups. **Results:** Our findings reveal significant alterations in 24 metabolites, including upregulation of Phenylalanine, fumarate, and hypoxanthine, and downregulation of butyrate, threonine, and glutamate in the 24-hour post-SE group compared to naïve controls. Contrarily, the SE-resistant group exhibits distinct metabolic signatures, with upregulation of pyridoxine, propionate, and several amino acids, and downregulation of glucose and ethanol compared to naïve controls. Notably, ribose and succinate levels are higher in the SE-resistant group compared to the 24-hour post-SE group. Clustering analysis further highlights the unique metabolic profile of the SE-resistant group. **Conclusion:** The findings showed that specific metabolites exhibit distinct patterns in SE-induced and SE-resistant groups, indicating potential markers for disease progression and treatment response. The distinct metabolic signatures between SE-induced and SE-resistant groups underscore the complexity of TLE pathophysiology. Further research is necessary to clarify the underlying mechanisms and validate these findings for clinical application.

https://doi.org/10.5327/CBN240593

Early reactivation of Chagas disease in the central nervous system after heart transplant: case report

Alexandra de Oliveira Lopes[1], Maria Luiza Nóbrega Lima Albuquerque[1], Gustavo Carvalho Oliveira Gonçalves Machado[1], Rafaela Pessoa Alves Luso[1], Bernardo Gomes Muffato[1], André Luís de Oliveira Silveira[1], Italo Pena Guimarães[1], Sabrina Gesteira Souza[1], Paulo Pereira Christo[1], Breno Franco Silveira Fernandes[1]

[1]Universidade Federal de Minas Gerais, Hospital das Clínicas, Belo Horizonte MG, Brazil.

Correspondence: Alexandra de Oliveira Lopes; Email: alexandramoraes11@gmail.com.

Case presentation: A 57-year-old female patient, previously diagnosed with Chagas cardiomyopathy, underwent heart transplantation 3 months ago. She was admitted to a quaternary hospital following her first-ever seizure episode. At the time of admission, she was on Cyclosporine and Mycophenolate Mofetil post-transplant and did not present with focal neurological deficits on initial neurological examination. Initially, a CT scan showed hypodensity in the right anterior opercular region with mild mass effect. Magnetic resonance imaging (MRI) confirmed a lesion with subcortical signal alteration in the right peri-rolandic region characterized by hypersignal on T2/FLAIR, hyposignal on T1, irregular central enhancement with contrast, foci of hyposignal on SWI, no diffusion restriction, measuring 27x27 mm. Cerebrospinal fluid analysis revealed: glucose 73 mg/dL, proteins 35.2 mg/dL, 3 cells (88% lymphocytes), negative cultures, serologies, and meningoencephalitis panel. Subsequently, Trypanosoma cruzi DNA detection in the cerebrospinal fluid via polymerase chain reaction was positive. Given the diagnosis of probable Chagas disease reactivation with an expansive lesion in the central nervous system (CNS), treatment with Benznidazole 5 mg/kg/day for 60 days was initiated. Additionally, she started levetiracetam for seizure control, with no recurrence of events. A follow-up MRI showed slight reduction in lesion dimensions post-treatment, confirming therapy efficacy. **Discussion:** Chagas disease is a complication of Trypanosoma cruzi infection, endemic in tropical countries and regions with low socioeconomic status. It rarely affects the CNS during acute disease or reactivation in the chronic phase, predominantly in immunocompromised individuals. About 89% of cases occur in HIV-infected individuals, with the remainder in post-transplant patients, undergoing chemotherapy, hematologic neoplasms, or immunosuppression due to autoimmune diseases. Acute disease presents as meningoencephalitis or cerebral abscess, while chronic forms manifest as mass-effect lesions with peripheral contrast enhancement, perilesional edema, and necrotic centers. Common symptoms include focal neurological deficits (47%) and seizures (32%). Diagnosis requires confirmation of the parasite in cerebrospinal fluid or lesion biopsy (gold standard). Treatment involves Benznidazole at 5-7 mg/kg/day for 60-90 days for acute and reactivated disease, with a guarded prognosis, especially in reactivation, where in-hospital mortality exceeds 70%. **Final comments:** Reactivation of Chagas disease in the CNS is rare but increasingly recognized due to the widespread use of immunosuppressants. Despite its rising relevance, the literature still lacks comprehensive evidence on epidemiology, diagnosis, and treatment, necessitating further research for better understanding and management of the disease.

Early stroke as a primary manifestation of inborn error of immunity

Carolina Chong-Silva[1], Daniel Kazuo-Tomoto[1], Francisca Mirian Moura Lacerda[1], Samir Farhat Hach[2], Fernanda Manfroi-Guimarães[2], Lifkyn Remboski[1], Camila Andrade Neix[1], Gesmar Rodrigues Silva Segundo[3], Herberto José Chong-Neto[4]

[1]Universidade Paulista, Sorocaba SP, Brazil.
[2]Universidade Positivo, Curitiba PR, Brazil.
[3]Universidade Federal de Uberlândia, Uberlândia MG, Brazil.
[4]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Carolina Chong e Silva; Email: carol.chong.silva@gmail.com.

Case presentation: A 6-year-old female patient presented with a history of multiple ischemic and hemorrhagic strokes with one year old, resulting in cerebellar ataxia, nystagmus, and right hemiparesis, associated with recurrent fever and livedo racemosa. She has no siblings, and her parents are not consanguineous. Magnetic Resonance Imaging showed an intraparenchymal hematoma in the left temporal lobe in the acute stage, signs of perilesional ischemia, and hemoventricle signs. Laboratory evaluation shows red blood cells=4.91 x 106/mL, hemoglobin=12.4g/dL, white blood cells=6.1 x 103/mL, neutrophils=4.3 x 103/mL, lymphocytes=1.2 x 103/mL, and platelets=217 x 103/mL. IgE<25IU/mL, IgG=467mg/dL, IgM=13.8mg/dL, and IgA=21.3mg/dL. Lymphocyte subtypes show CD3+=853 cells/microliter (81.2%), CD4/CD8=1.41, CD19+=113 cells/microliter (10%), and CD16/56=81 cells/microliter (8.8%). Due to the clinical history, genetic sequencing of the CECR1 gene was performed, showing a homozygous substitution at position -2 of the splice acceptor site in intron 6, c.847-2G>A. This is a highly conserved region with no alteration in phylogenetic studies and is predicted to be pathogenic. To confirm the functional alteration, the activity of Adenosine Deaminase-2 (ADA-2) was tested in dried blood spot, showing 0.0 mU/g of protein, confirming the loss of gene function and the pathogenicity of the mutation. **Discussion:** ADA-2 has partial structural homology with ADA-1. Both proteins convert adenosine to inosine and 2'-deoxyadenosine to 2'-deoxyinosine. ADA-2 deficiency is an immune dysregulation disease caused by an autosomal recessive mutation in the CECR1 gene, leading to mild immunodeficiency, more evident in B cells, accompanied by recurrent fevers and a spectrum of pathological vascular characteristics. **Final comments:** The authors presented a child with an inborn error of immunity with the primary manifestation of cerebrovascular disease due to a mutation in the CECR1 gene, causing loss of gene function and confirmed by the extremely reduced activity of ADA-2.

https://doi.org/10.5327/CBN240595

Early vs classical facioscapulohumeral muscular dystrophy onset: a specialized muscular center profile

Filipe Tupinambá Di Pace[1], Cristiane Araújo Martins Moreno[1], Clara Gontijo Camelo[1], Gabriel Saboia de Araújo Torres[1], Raquel Diógenes Alencar Sindeaux[1], Gabriella Corrêa Dousseau[1], Mariana Hiromi Manoel Oku[1], Rodrigo de Holanda Mendonça[1], André Macedo Serafim Silva[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Filipe Tupinambá Di Pace; Email: filipedipace@gmail.com.

Background: Facioscapulohumeral muscular dystrophy (FSDH) is the second most common muscular dystrophy in adults, being termed early-onset (EO) when it starts until the age of 10. FSHD is divided into types 1 and 2 based on genetic markers, both caused by an abnormal expression of the DUX4 gene. This study presents a Brazilian FSHD cohort comparing EO and classical-onset (CO) aspects. **Objective:** To compare the demographic, clinical, and genetic profile of patients with EO versus CO in FSHD. **Methods:** Data were extracted from electronic medical records, between December 2016 and February 2024. Key data points included patient registration, birth date, sex, family history, age and site of the first symptom, genetic test results, muscular and extra-muscular involvement. **Results:** 46 patients were included, 14 (30.4%) in the EO and 32 (69.5%) in the CO group, in which females were affected in 57.1% vs 40.6%, and no disease family history was found in 53,8% vs 25%. The mean age at the first symptom was 5.8 (2-10) and 31.7 (12-70) years, and the mean time of disease duration was 24 (3-60) and 18 (3-49) years for EO and CO, respectively. Genetic tests were performed on 78% of patients. All CO patients had FSHD type 1, while two EO patients had FSHD type 2. The EO and CO groups started the disease in the upper limbs at 41.7 % vs 60%, in the lower limbs at 25% vs 40%, and in the face at 33.3% vs none. Facial involvement was present in 87.8% of patients, with no difference between groups at the last appointment. Wheelchair users were more frequent in the EO group (23.1% vs 11.5%), and the mean age at the first symptom was 3.3 vs 6 years compared to the ambulatory EO group. Among all patients, the time of disease duration of ambulatory and non-ambulatory was 22.9 and 21.8 years. 21 patients had the pulmonary functional tests available, 63,6% of them were normal, with no difference between groups. Regarding extra-muscular involvement, pain was a frequent symptom (86.3%), and cardiac test results, were available for 8 patients in the EO group and 17 in the CO group, showing abnormality in 20% of them (25% vs 17.6%). Ophthalmological and hearing exams were available for a few patients and were not evaluated. **Conclusion:** This FSHD cohort provides important insights into the disease profile among Brazilian patients. Key findings in the EO group include a higher frequency of affected females, less family history, more cases of FSHD type 2, the significance of age at first symptom over disease duration regarding wheelchair dependency, and more cardiac involvement. Notably, none of the CO patients presented with facial onset. Continued investigation of our patients' profiles is crucial for a better understanding of early symptoms and prognosis.

Early-onset myopathy, areflexia, respiratory distress, and dysphagia (EMARDD): a case report and description of a novel variant

Laura Alonso Matheus Montouro[1], Janaina Moraes de Araújo[1], Regina Celia Ajeje Pires Albuquerque[1], Charles Marques Lourenço[1], Erica Nogueira Coelho[1], Eduardo de Paula Estephan[1], João Aris Kouyoumdjian[1], Carla Renata Graça[1], Maria da Penha Ananias Morita[1]

[1]Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto SP, Brazil.

Correspondence: Laura Alonso Matheus Montouro; Email: lauramontouro@hotmail.com.

Case presentation: A 5-month-old female infant comes to the hospital with 1 week progressive respiratory distress. She was born at 41 weeks gestation by C-section without complications. There is no consanguinity, nor similar familial cases. On physical examination: absence of dysmorphisms, adequate visual/social contact, weak cry, decreased limb movement, global hypotonia and areflexia, intense weakness of the axial muscles. During hospitalization, she developed persistent respiratory failure and dysphagia. Creatine Phosphokinase: 60 U/L, whole body MRI shows diffuse muscle groups hypotrophy, no organomegaly and lungs hypoexpansion. Electroneuromyography: reveals a myopathic pattern on proximal limb muscles and on paravertebral muscles, in addition, these with spontaneous activity and complex repetitive discharge. Muscle biopsy: neonatal myosin and embryonic immunohistochemical studies reveal a large amount of positive fibers. Dried blood spot tests (Pompe/Gaucher/Niemann-Pick diseases, aminoacidopathies and disorders of urea cycle/organic/fatty acids/purine metabolism): negative. Serum/urinary carnitine and urinary organic acids: normal. MLPA for SMN1/SMN2: no deletions in the SMN1. Exome study: homozygous missense variant (c.229C>T) in MEGF10. **Discussion:** Infantile hypotonia with respiratory weakness can be related to the brain, anterior horn of the spinal cord or neuromuscular structures. Congenital myopathy is responsible for 14% of cases of neonatal hypotonia, occurs due to a structural defect in the components of the muscle fiber and is a genetically heterogeneous group with around 40 genes involved. The most prevalent genes are: RYR1, NEB, ACTA1, ADSSL1, SELENON, MTM1, DNM2, and TPM3. In 2011, the first study, with 7 patients from 5 families, of congenital myopathy associated with MEGF10 by Logan et al. This gene is related to two phenotypes: Early-onset Myopathy with Areflexia, Respiratory Distress & Dysphagia (EMARDD) (congenital myopathy 10A) and a late-onset syndrome, usually associated with minicore lesions on muscle biopsy (congenital

myopathy 10B). Our proband has a EMARDD phenotype and a homozygous variant that promotes the replacement of arginine by tryptophan in codon 77 (p.Arg77Trp), arginine in this position is conserved in different species and infrequent in heterozygous on population (3:141.000). However, it has never been previously described in the literature/variant repository. To date, there are 32 cases of EMARDD associated with MEGF10 in the literature. Only one reported in Brazil, presented at a national congress in 2022. An experimental study identified that selective serotonin reuptake inhibitors (SSRI) have a beneficial effect in vitro/in vivo animal models. **Final comments:** MEGF10 myopathy must be remembered as a cause of infantile hypotonia with respiratory failure due to prognosis, genetic counseling and, mainly, due to the prospect of SSRI as a treatment.

Eaton Lambert myasthenic syndrome with cerebellar ataxia misdiagnosed as Guillain-Barré spectrum

Raíssa Josefa Pereira de Moura[1], Mayhara Rosany da Silva Santiago[1], Nereu Alves Lacerda[1], Ana Caroline Paiva Simeao[1], Renata Amaral Andrade de Mendonça[1], Natália Nunes Tenório[1], Heron Alves Vale[1], Maria Luisa Roberto Lima Lisboa[1], Ana Beatriz Roberto Lima Borba[1], Ana Carolina Martins Fragoso Carneiro[1],

[1]Hospital Pelópidas da Silveira, Recife PE, Brazil.

Correspondence: Raissa Josefa Pereira de Moura; Email: rayssamoura16@gmail.com.

Case presentation: A 57 years old woman, smoker (30 pack-years), presented with a 1 month lower limbs proximal weakness, evolving with diplopia and cerebellar ataxia. Physical examination revealed o ophthalmoparesis, a grade IV ileopsoas and quadriceps weakness, areflexia on lower limbs and cerebellar ataxia. Initially a Guillain Barré syndrome (Miller Fisher spectrum) was considered and intravenous human immunoglobulin was administered with significant clinical improvement. During diagnostic investigation, cerebrospinal fluid showed mild hyperproteinorrachia (72 mg/dl - VR 45 mg/dl) with no pleocytosis (02 cells). However, during the subsequent months, there was further clinical deterioration and was performed new clinical investigation. The electroneuromyography exam showed a presynaptic neuromuscular junction disorder (increment >100%) compatible with Eaton Lambert myasthenic syndrome (LEMS). All neoplastic screening was negative. **Discussion:** LEMS is a rare neuromuscular junction autoimmune disorder. In most patients serum antibodies against P/Q voltage-dependent calcium channels bind to the presynaptic motor nerve terminal and inhibit depolarization-dependent calcium influx, reducing the acetylcholine release at the neuromuscular junction. LEMS may occur as a paraneoplastic disorder, in association with an underlying cancer, or as part of a more generalized autoimmune state. The patient in this report underwent all accessible paraneoplastic screening, which was negative. The clinical findings of this pathology include gradual onset proximal muscle weakness and absent or reduced reflexes but we highlight the occurrence of cerebellar ataxia. This association is due to the high expression of autoantibodies in the cerebellar system and few case reports and small series of patients with simultaneous cerebellar ataxia and LEMS have been described, including one patient in the original report by Eaton and Lambert. Generally, electrophysiological studies have demonstrated decremental responses to low-frequency repetitive nerve stimulation, and may also show post-exercise facilitation greater than 100%. Effective, long-term symptomatic treatment options include agents that increase neuromuscular transmission and immunomodulators. **Final comments:** LEMS associated with ataxic syndrome is uncommon; a few reports in the literature demonstrate an association between these syndromes and autoantibodies against voltage-gated calcium channels, especially when the patient has some type of underlying neoplasm; our patient was screened and is being followed up, however, to date, there is no evidence of underlying malignancy. However, LEMS symptoms may appear before the discovery of an underlying malignancy, which demonstrates the need for follow-up and periodic paraneoplastic screening.

Background: According to the Ministry of Health, Brazil has about 2 million people with some form of dementia, which is expected to triple by 2050, mainly affecting the elderly. Alzheimer's disease and dementia with Lewy bodies are among the most worrisome clinical forms of neurodegenerative dementia. Studies which describing the pattern of onset and distribution of this disease in Brazil are essential due to its impact on public health with the increase in life expectancy in the country. **Objective:** To describe the epidemiological profile of patients hospitalized with dementia using different variables in the regions of Brazil. **Methods:** This is an ecological, descriptive study with a quantitative approach The information was obtained by collecting secondary data from the SUS Hospital Information System (SUS/HIS), provided by the Department of Informatics of the Unified Health System (DATASUS), from 2014 to 2023. The target population is made up of patients diagnosed with dementia, assessing the distribution of the number of visits by region and correlating with gender, age group, race and year. **Results:** There were 28,124 hospitalizations for dementia in Brazil during the period analyzed, with the South having the highest incidence of hospitalizations (2.12 per 100000 inhabitants), followed by the Southeast (1.86 per 100000 inhabitants). During this period, the highest incidence occurred in 2023, with a value of 1.46 per 100000 inhabitants, and the lowest incidences were in 2020, with 1.15 per 100000 inhabitants, and 2021, with 1.19 per 100000 inhabitants. In addition, there were 11,934 cases among white people, followed by brown people with 7,048 cases. There was no significant difference between women (13,983 cases) and men (14,141 cases), increasing linearly with age, especially over 60 years, which accounts for 62.33% of the cases (17,531 cases). **Conclusion:** It is evident that the population most at risk of dementia is mainly people over 60 years old, white and brown people, living in the south and southeast regions, which according to the 2022 IBGE census represent the majority of these populations justifing the figures. The low incidences in 2020 and 2021 may be related to the impact of the Covid-19 pandemic directly on the notifications. The number of cases of hospitalization for dementia is therefore worrying and on the rise, highlighting the need for further studies on the subject.

Ecological study of meningococcal infection in the Southeast region of Brazil from 2015 to 2022

Danielle de Lima Pimentel[1], Gabrielle Gomes Garcia[1]

[1]Universidade Federal Fluminense, Niterói RJ, Brazil.

Correspondence: Danielle de Lima Pimentel; Email: daniellepimentel@id.uff.br.

Background: Meningococcal infection leads to diseases such as meningitis and meningococcemia, which may cause permanent sequelae and death. Neisseria meningitidis infection is related to contact with an asymptomatic, sick individual or through direct contact with respiratory secretions. Therefore, studies that analyze its incidence in recent years, including how it has been affected by the COVID-19 pandemic, are necessary in order to take action to control these diseases. **Objective:** To analyze the incidence of meningococcal infection in the Brazilian Southeast region. **Methods:** This is a descriptive ecological study with a quantitative approach, using data from secondary sources, through the Hospital Information System of the Brazilian Unified Health System (SIH/SUS) provided by the Ministry of Health, accessed through the Department of Informatics of the Unified Health System (DATASUS). Data covered the period from 2015 to 2022 for the population residing in the Southeast region of Brazil. Variables included year of hospitalization, age group, sex, and race/ethnicity, assessing the number of hospitalizations and mortality rates. **Results:** 2869 cases of hospitalizations were identified, of which 572 occurred in 2015, 442 in 2016, 435 in 2017, 410 in 2018, 380 in 2019, 220 in 2020, 181 in 2021 and 229 in 2022. Among hospitalizations in the Southeast region, the most affected groups were children up to 4 years old with 888 cases (31%), males with 1584 cases (55.2%) and individuals identifying as white with 1025 cases (35.7%). The mortality rate is higher in individuals aged 80 years or older (41.98 per 100 patients), in the female population (15.25 per 100 patients) and in the black population (19.86 per 100 patients) and yellow population (19.44 per 100 patients). **Conclusion:** Elderly, female, black and yellow population are at higher risk of death from meningococcal infection. In addition, there has been a significant decrease in the number of hospitalizations, especially from 2020 onwards, possibly correlated with the COVID-19 pandemic and the resulting social isolation reducing transmission. However, studies indicate a decline of meningococcal C immunization coverage in this period, which could lead to an increase in its incidence. Despite the limitations of the study, such as the inability to make a cause-and-effect association, the results highlight its importance for decision-making to face this disease.

Ecological study of migraines and other headache syndromes in Southern Brazil, 2014 - 2023

Danielle de Lima Pimentel[1], Verônica Guimarães Irias de Lima[1], Letícia Cavalcante da Costa Aragão[2], Danilo Pereira Fermino[3], Izabella de Campos Marinho[1]

[1]Universidade Federal Fluminense, Niterói RJ, Brazil.
[2]Universidade Federal do Delta do Parnaíba, Paraíba PI, Brazil.
[3]Unisalesiano, Araçatuba SP, Brazil.

Correspondence: Danielle de Lima Pimentel; Email: daniellepimentel@id.uff.br.

Background: According to the World Health Organization, approximately 50% of the world's population suffers from acute headache at some point in their lives. Headache has potentially disabling features, negatively affecting well-being and causing economic and social harm. Some studies have already shown the major impact of headache on the health system in Brazil, but few studies have

investigated the socio-demographic aspects of the high incidence of cases in the southern region. **Objective:** To analyze the epidemiological profile of patients hospitalized with migraine and other headache syndromes due to different variables in southern Brazil. **Methods:** This is a descriptive ecological study with a quantitative approach. The information was obtained by collecting secondary data from the SUS Hospital Information System (SUS/HIS), provided by the Department of Informatics of the Unified Health System (DATASUS), from 2014 to 2023. The target population of this study is made up of patients hospitalized with a diagnosis of migraine and other headache syndromes in the Southern Region of Brazil, evaluating the distribution of the number of visits and correlating it with gender, age group, race and year. **Results:** During the period analyzed, there were 96,348 hospitalizations for migraine and other brain pain syndromes in Brazil, with the South accounting for 24,974 of these hospitalizations. The South had the highest incidence of hospitalizations (8.37 per 100000 inhabitants) in Brazil. The incidence of hospitalizations in the Brazilian population increased linearly from 2014 (3.87 per 100000 inhabitants) to 2019 (5.77 per 100000 inhabitants), and suffered a decrease in 2020 (4.1 per 100000 inhabitants) and 2021 (3.99 per 100000 inhabitants), which increased again in 2022 (4.84 per 100000 inhabitants) and 2023 (5.09 per 100000 inhabitants). The most affected age group was 40 to 44 years with 2212 cases, much more frequent in women (16125 cases) than in men (8723 cases) and in white people with 20131 cases. **Conclusion:** The identified population at risk for headache susceptibility corroborates data from other studies, with genetic factors, hormones, and the menstrual cycle as the main causes that could explain this prevalence. In addition, the COVID-19 pandemic may have influenced the number of cases of hospitalization for migraine, as a decrease was only observed in 2020 and 2021, the most significant period of the pandemic.

Background: Bacterial meningitis (BM) is a severe infection that affects the central nervous system, predominantly in children, with high morbidity and mortality and rapid symptomatic progression. Early detection is essential for a better prognosis, as this disease involves severe complications and irreversible neurological sequelae. The main pathogenic agents associated with this infection are Streptococcus pneumoniae (S. pneumoniae), Neisseria meningitidis (N. meningitidis), and Haemophilus influenzae (H. influenzae). **Objective:** To analyze the morbidity and mortality of bacterial meningitis in the preschool population in the Southeast region from 2017 to 2023. **Methods:** This is an ecological, cross-sectional, descriptive study with a quantitative approach, conducted in May 2024, using data collected from the Hospital Information System of SUS (SIH/SUS - Sistema de Informações Hospitalares do Sistema Único de Saúde), available from the Department of Informatics of the Unified Health System (DATASUS - Departamento de Informática do Sistema Único de Saúde). The variables used were hospitalizations, total cost, deaths, and mortality rate. The collected data were organized in Microsoft Excel spreadsheets and analyzed using descriptive statistics. **Results:** The analysis revealed the mortality rates, deaths, hospitalizations, and total cost, respectively, for each state in the Southeast Region. In Minas Gerais, the mortality rate was 3.33% (18 deaths and 540 hospitalizations) with a total cost of R$1,585,164.03; in Espírito Santo, the mortality rate was 5.88% (5 deaths and 85 hospitalizations) with a total cost of R$387,698.65; in Rio de Janeiro, the mortality rate was 7.69% (23 deaths and 299 hospitalizations) with a total cost of R$653,258.55; in São Paulo, the mortality rate was 2.85% (54 deaths and 1,895 hospitalizations) with a total cost of R$5,779,650.62. In this context, it is noticeable that the state of São Paulo has the highest allocated funds but the lowest mortality rate compared to the other states. Hence, there is evidence of greater vulnerability in the distribution of funds in Brazil, contributing to the worsening situation in some more fragile states in regions such as the Southeast. **Conclusion:** The data evaluated from 2017 to 2023 show the disparity in the funds allocated among the states in the Southeast region. Bacterial meningitis is responsible for approximately 5 to 40% of deaths in children with this condition, emphasizing the need for significant attention to the care of this population, especially in hospitals with exposure to infections and in preschool children with pre-existing conditions, in order to assist in the prevention of bacterial meningitis.

Background: Hereditary spastic paraplegias (HSP) constitute a group of rare, neurodegenerative genetic disorders characterized by spastic hypertonia, hyperreflexia, muscle weakness in the lower limbs, and impaired vibratory sensation, resulting in the gradual loss of balance and walking ability. Due to clinical and genetic heterogeneity, as well as functional deficits, defining sensitive biomarkers for use in clinical trials and evaluating the disease course is challenging. **Objective:** To assess the effect of a 12-week strength and functional exercise protocol on the motor symptoms in individuals with hereditary spastic paraplegia and to analyze the sensitivity to change of the Clinician-Reported Outcome measures, performance outcomes, and Digital Health Technology. **Methods:** This is an adaptive cross-over randomized clinical trial. Initially, 20 patients diagnosed with HSP will be recruited. The study will be adapted based on an interim data analysis after 24 weeks, which will assess whether the effect is promising, favorable, or unfavorable through statistical analysis. Outcomes will be measured through the disease stage, Spastic Paraplegia Rating Scale, Ashworth Scale (Lower Limbs), muscle strength test (Medical Research Council), muscle strength test using manual dynamometry, Timed Up and Go, 10-meter walk test at maximum and self-selected speeds, kinematic gait evaluation, Clinical Global Impression of Change scale, Fall Efficacy Scale - Brazilian Version, Goal Attainment Scale, and the SF-36 Quality of Life Questionnaire. After randomization, the intervention group will have two online sessions per week, each lasting 60 minutes, for 12 weeks. Participants will be reassessed immediately at the end of the interventions, and group crossover will be conducted. Preliminary **Results:** To date, 10 participants have been included. The sample consists of 50% male participants. The mean age of participants is 46.9 years (±18.88), indicating a wide age range. The mean duration of the disease among participants is 19.0 years (±8.07). Regarding disease subtypes, 80% of participants were diagnosed with SPG4 and 20% with SPG10. Concerning the disease stage, 20% of participants are in stage 1, 40% in stage 3, and 40% in stage 4. We will have the results of the comparison between treatments only after the conclusion of the study. **Conclusion:** The findings of this study may contribute to the development of an exercise protocol aimed at treating motor symptoms associated with the disease. Furthermore, the results may assist in identifying the sensitivity to change and clinical meaningfulness of the changes in clinical outcome assessments and digital health technologies. This information is crucial for the design of symptomatic and disease-modifying therapy trials.

Effect of organic purple grapes on behavioral tests of self-grooming and social interaction in an animal model of Valproic acid-induced autism

Ana Carolini Toporowicz Soares[1], Klaus Johann Jacques Schebek Teixeira[1], Kassielly Longo Brizola[1], Thayná Patachini Maia Becker[1], Alessandra Betina Gastaldi[1], Gabriela Borgmann[1], Katherine Plautz[1], Karine Louize Vincenzi Lüetke[1], Débora Delwing-dal Magro[2], Daniela Delwing-de Lima[1]

[1]Universidade da Região de Joinville, Joinville SC, Brazil.
[2]Fundação Universidade Regional de Blumenau. Blumenau SC, Brazil.

Correspondence: Ana Carolini Toporowicz Soares; Email: acstoporowicz@gmail.com.

Background: Autism spectrum disorder (ASD) is characterized by common patterns of social communication and restricted and repetitive sensorimotor behaviors of early onset, altered brain development and neural reorganization. ASD is influenced by the interaction of genetic and environmental factors, with possible prenatal exposure to toxic substances. In this sense, Valproic acid (VPA) significantly increased the incidence of autism in children of mothers who used this medication during the first trimester of pregnancy, with studies that show an increase in oxidative stress in ASD patients. Furthermore, the polyphenolic compounds present in organic purple grapes are known for their neuroprotective potential. **Objective:** To verify the effect of hydroalcoholic extract (HE) of organic purple grapes, at concentrations of 30, 100 and 150mg/kg, in modulating autistic-like behavior in male Wistar rats, induced by VPA. **Methods:** The project was approved by the Research Ethics Committee (CEUA 02/2022). The pregnant females received 800mg/kg of VPA diluted in 0.9% saline solution, intraperitoneally, in a single administration in the prenatal period (12th day of pregnancy). The male offspring were subjected to behavioral tests of self cleaning and social interaction to confirm the motor and psychotherapeutic responses typical of ASD. After, received treatment with the extract from organic purple Vitis vinifera at concentrations of 30mg/kg, 100mg/kg and 150mg/kg or saline as a control, via gavage, for 15 days and

underwent behavioral tests again to evaluate responses to treatment. In the end, they were euthanized by decapitation. **Results:** Behavioral tests showed stereotypy in the autistic group in the self-grooming test, and HE 150mg/kg decreased movement time, reducing repetitive behavior. In the social interaction test, the interaction time with the animal was shorter in the autistic group compared to the autistic control group. When evaluating interaction time with the object, the autistic group spent more time with the object than the autistic control group. HE at all concentrations reversed this time when compared to the autistic control group. **Conclusion:** This study demonstrated that the HE of organic purple grapes can modulate autistic-like behaviors in rats induced by AVP. The extract, in different concentrations, were effective in reducing repetitive behaviors and improving social interaction. These findings suggest a neuroprotective potential of polyphenolic compounds present in grapes, offering a promising perspective for future adjuvant therapies in the treatment of ASD.

https://doi.org/10.5327/CBN240604

Effect of organic purple grapes on brain antioxidant enzyme activity in an animal model of autism induced by Valproic acid

Ana Carolini Toporowicz Soares[1], Klaus Johann Jacques Schebek Teixeira[1], Luana Gabriely de Almeida Campos[1], Mirela Parissa Bondan Misagh[1], Gustavo Schuetzler Gomes Fernandes[1], Thayná Patachini Maia Becker[1], Alessandra Betina Gastaldi[1], Natalia Cavichioli[1], Débora Delwing-dal Magro[2], Daniela Delwing-de Lima[1]

[1]Universidade da Região de Joinville, Joinville SC, Brazil.

Correspondence: Ana Carolini Toporowicz Soares; Email: acstoporowicz@gmail.com.

Background: Developmental disorders have been the focus of neuroscience studies for many years and autism spectrum disorder (ASD) has received prominence in research over the last 30 years. The Valproic acid (VPA) significantly increased the incidence of autism in children of mothers who used this medication during the first trimester of pregnancy and studies demonstrate an increase in oxidative stress in individuals with ASD. The polyphenolic compounds present in grapes cause an increase in brain antioxidant activity. **Objective:** To reproduce autistic-like behavior in rats induced by VPA and evaluate the protective effects of hydroalcoholic extract (HE) of organic purple grapes at concentrations of 30, 100 and 150mg/kg on oxidative stress parameters in brain structures (cerebral cortex and cerebellum). **Methods:** The project was approved by the Research Ethics Committee (CEUA 02/2022). The pregnant females received 800mg/kg of VPA diluted in 0.9% saline solution, intraperitoneally, in a single administration in the prenatal period (12th day of pregnancy). The male offspring underwent behavioral tests to confirm the motor and psychotherapeutic response of autism. They were then administered HE (30mg/kg, 100mg/kg and 150mg/kg) or saline, via gavage, for 15 days, and were euthanized by decapitation to remove the cerebral cortex and cerebellum for analysis of the enzymatic antioxidant activity of superoxide dismutase (SOD), catalase (CAT) and glutathione peroxidase (GSH-Px). Data were analyzed by one-way ANOVA, followed by the Duncan post hoc test, when indicated ($p<0.05$). **Results:** Analysis demonstrated that ASD decreased SOD activity, while HE at a concentration of 30mg/kg partially reversed it and at concentrations of 100mg/kg and 150mg/kg completely reversed the enzymatic decrease in the cerebral cortex, while in the cerebellum there was no alteration in this enzyme. The model and administration of HE at different concentrations did not alter CAT activity in the cerebral cortex and cerebellum and GSH-Px activity in the cerebral cortex. On the other hand, GSH-Px activity in the cerebellum decreased in the group of animals with ASD. HE at a concentration of 30mg/kg partially reversed and at 100mg/kg and 150mg/kg, completely reversed the enzymatic decrease in rats with ASD. **Conclusion:** The animal model of autism-like behavior altered enzymatic antioxidant activity in the cerebral cortex and cerebellum of rats and the HE from organic purple grapes reversed the alterations in the brain, indicating its antioxidant capacity.

Effect of theta burst transcranial magnetic stimulation associated with transcranial direct current stimulation to improve unilateral spatial neglect after stroke: a randomized controlled trial study protocol

Luana Aparecida Miranda[1], Fernanda Cristina Winckler[1], Gabriela Vieira de Paula[1], Tainá Gabriela Ricci[1], Natália Cristina Ferreira[1], Ricardo Silva Carvalho[1], Luiz Felipe Gomes Queiroz[1], Silméia Garcia Zanati Bazan[1], Gustavo José Luvizutto[2], Rodrigo Bazan[1]

[1]Universidade Estadual Paulista, Faculdade de Medicina de Botucatu, Botucatu SP, Brazil.
[2]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Ricardo Silva Carvalho; Email: carvalho.ricardo.med@gmail.com.

Background: Approximately 38% of patients who survive right hemisphere stroke present perception deficits, characterized by the syndrome of unilateral spatial neglect, with a likelihood of poor functional prognosis. Transcranial magnetic stimulation, or transcranial direct current stimulation, is employed in these patients to rebalance hemispheric activity. **Objective:** To assess the safety and efficacy of continuous theta burst transcranial magnetic stimulation in the left parietal cortex followed by anodic transcranial direct current stimulation in the right parietal cortex associated with rehabilitation to improve unilateral spatial neglect. **Methods:** This is a randomized, double-blind, multicenter clinical trial involving adult patients with unilateral spatial neglect following stroke, who will be randomized into three groups: Priming Group - 17 patients will receive continuous theta burst transcranial magnetic stimulation in the left parietal region followed by anodic transcranial direct current stimulation in the right parietal lobe; Conventional Group - 17 patients will receive anodic transcranial direct current stimulation in the right parietal region, and Sham Group - 17 patients will receive transcranial magnetic stimulation and sham transcranial direct current stimulation in the right parietal region, across 15 sessions distributed over 3 sessions per week lasting 30 minutes each. All groups will undergo physical therapy sessions, with assessments conducted at screening, after 8 sessions, and at the end of treatment. Follow-up of these patients will occur at 3, 6, and 12 months after the last session. **Results:** Based on the results of these studies, it will be possible to determine the effectiveness of the concomitant use of two transcranial stimulation techniques–continuous theta burst transcranial magnetic stimulation in the left parietal cortex followed by anodal transcranial direct current stimulation in the right parietal cortex–in improving unilateral spatial neglect, functional disability, quality of life, and self-efficacy in post-stroke patients. **Conclusion:** This is the first proof-of-concept randomized controlled trial to assess the effects of theta burst transcranial magnetic stimulation combined with anodic transcranial direct current stimulation on the perceptual performance post-stroke. Due to the combined clinical and functional measurements, this trial is intended to provide insights into the underlying post-stroke recovery processes and whether these can be influenced by combined therapies.

Correspondence: Larissa Coutinho de Lucena; Email: larissa.lucena@isd.org.br.

Background: Alzheimer's disease (AD) leads to cognitive decline and loss of functional capacity. Transcranial direct current stimulation (tDCS) emerge as a potential therapy due to its ability to modulate cortical excitability. However, varying protocols and individual differences can hinder their effectiveness. Standardizing the most appropriate stimulation and effective parameters, such as intensity, polarity, frequency, targets, and duration, can help establish a reliable protocol for healthcare professionals, addressing current inconsistencies. **Objective:** To analyze the effects of transcranial direct current stimulation (tDCS) on the cognitive function and functional capacity of individuals with AD. **Methods:** This systematic review with meta-analysis and meta-regression included randomized clinical trials published until May 2022. The review protocol is registered in PROSPERO (CRD42020151189) and follows PRISMA guidelines. The studies involved individuals with AD, aged 55-85, treated with tDCS and compared with a placebo group. Subgroup analysis and meta-regression were conducted to address significant heterogeneity ($I2>75\%$) by considering moderating variables. **Results:** A total of 166 participants were subjected to active tDCS or sham stimulation, with an average age ranging from 64.22±(3.64) to 81.6±(8.0), and there were no participants with advanced-stage AD. In the studies included in the systematic review, there was a difference in the number of sessions, which ranged from a single session to 10 sessions; the stimulation time per session ranged from 15 minutes to 30 minutes; the total duration of the treatment ranged from one day to two weeks and all the studies investigated the anodal modality. A meta-analysis was conducted, which showed that tDCS did not have a greater effect than placebo on cognitive function in AD (standardized mean difference=0.69; 95% CI 0.00 to 1.38; $p=0.05$). The subgroup analysis conducted for the type of stimulation included studies that employed anodal tDCS and cathodal tDCS. From the results of this analysis, statistical significance was observed for the experimental group in the studies that investigated the application of anodal tDCS (standardized mean difference=0.76; 95% CI 0.20 to 1.31; $p=0.008$; $I^2=78\%$). Meta-regression suggested a significant influence of anodic tDCS with current intensity of 1.5 mA on cognitive function ($p=0.001$). **Conclusion:** Anodal tDCS have demonstrated the ability to improve cognitive function in AD by modulating neural activity. These therapies are safe and well-tolerated, being promising as adjuncts to available pharmacological treatments. Studies with greater methodological rigor and parameter standardization are warranted.

Background: The prevalence of neurodegenerative diseases has been increasing due to longer life expectancy, with women being disproportionately affected 2 to 3 times more often following menopause. Research has shown an association between hypovitaminosis D and several age-related conditions, including cognitive decline. **Objective:** To assess the impact of vitamin D, either alone or in combination with donepezil, on spatial memory in adult and aging ovariectomized rats. **Methods:** Under protocol number 123/2019 and with approval from the Ethics Committee for Animal Use (CEUA) of the university, female Wistar rats aged 60 and 120 days underwent ovariectomy (OVX). They received treatment 1, 4, or 8 months post-surgery. They were administered chronic doses of vitamin D (42IU/kg or 420IU/kg) and donepezil (1mg/kg), independently or in combination, for 21 days. Spatial memory was evaluated using the octagonal maze from day 18 to day 22 of the experiment. **Results:** The results revealed that 60-day-old rats subjected to OVX for 1 or 4 months did not display impairment in spatial memory. However, those aged 60 days and subjected to OVX for eight months exhibited spatial memory impairment, which was mitigated over time by administration of vitamin D at 420IU/kg alone or in combination with donepezil. Similarly, 120-day-old rats subjected to OVX for 1 or 4 months did not exhibit spatial memory impairment, whereas those subjected to OVX for eight months did show impairment. Treatment with vitamin D at 420IU/kg and donepezil alone improved spatial memory performance. Overall, rats subjected to longer OVX durations performed poorer in spatial memory tasks than controls. **Conclusion:** Vitamin D supplementation at 420IU/kg and donepezil, either alone or in combination, demonstrated neuroprotective effects concerning spatial memory in OVX rats.

Case presentation: An elderly male patient with a 10-year history of Type 2 Diabetes Mellitus (T2DM) presented with poorly controlled blood glucose levels, an unbalanced diet, and continuous treatment with insulin and oral hypoglycemics. He also had hypertension and hypercholesterolemia. The patient had a recurring acute lesion on his left hallux, originating from a keratinocyte callus, showing signs of inflammation and local infection, including lymphadenopathy in the leg and groin. Treatment involved removing the keratinocyte debris, cleansing the wound, applying a local disinfectant dressing, and starting oral antibiotic therapy. Continuous monitoring and antimicrobial dressings led to complete healing within 10 days without requiring amputation. **Discussion:** Diabetic peripheral neuropathy is a common and significant complication of diabetes mellitus. This condition results in a loss of sensation, making patients highly prone to repeated injuries, especially in the feet. Two types of nerve fibers can be affected in neuropathy: thin and thick. They can be damaged due to demyelination linked to metabolic defects, which affect Schwann cells and myelin production in the peripheral neurons. If thin fibers are injured, the patient may experience a decrease in general sensitivity, as well as paresthesia and hyperesthesia. Conversely, a lesion to thick fibers will result in a reduction in tactile perception. Peripheral neuropathy severely impairs protective sensation in the feet, making minor injuries such as small cuts or blisters go unnoticed and untreated. Poor blood sugar control and inadequate preventive care can lead to chronic wounds and infections, complicating the patient's condition. The recurrence of lesions at the same site highlights the critical need for early and continuous interventions. Proper cleaning and the use of advanced wound dressings, along with prompt antibiotic therapy, are crucial in controlling the infection and promoting rapid wound healing. Patient education on self-care and injury prevention is vital, especially for patients suffering from peripheral neuropathy. This ongoing follow-up not only supports wound healing but also reduces the risk of new injuries and serious complications, such as amputations. **Final comments:** Early and consistent intervention, along with patient education, proved effective in managing lesions associated with diabetic peripheral neuropathy. A multidisciplinary approach is essential for minimizing adverse effects and promoting efficient wound healing. This case underscores the importance of specialized follow-up and the use of advanced dressing technologies for infection control and health promotion. Regular monitoring and guidance to prevent recurrences are vital for improving the quality of life for diabetic patients.

Effective use of botulinum toxin for neuropathic pain management in a neuroma: a case report

Matheus Parra Barcelos de Mendonça[1], Camille Scabora de Melo[1], Mariana Almeida Lima[1], Bruna Andrade Vigo[1], Gabriel Taricani Kubota[2], Bruno Hojo Rebouças[2]

[1]Universidade de São Paulo, São Paulo SP, Brazil.
[2]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Matheus Parra Barcelos de Mendonça; Email: matheus.parra.barcelos@gmail.com.

Case presentation: This case presents a 66-year-old woman who suffered a deep second-degree and circumferential third-degree electrical burn on the left wrist and hand in 2017. She underwent left upper limb amputation at the elbow level and developed a neuroma at the residual limb involving the median and ulnar nerves. She exhibited phantom limb pain, neuropathic pain, myofascial nociceptive pain with trigger points in shoulder girdle muscles, as well as allodynia and hyperalgesia in the residual limb. The patient went through several interventions for pain control, such as mirror therapy, acupuncture, and pharmacotherapy with gabapentin, methadone, amitriptyline, pregabalin, and duloxetine without a satisfactory result. In December 2021, the patient underwent botox injections and neurolysis for treatment of the lateral neuroma, which resulted in significant symptom improvement. Since then, she has undergone other interventions, such as electrostimulation and nerve block. Currently, she is taking methadone, amitriptyline, and gabapentin daily, with dipyrone as needed. **Discussion:** A neuroma results from unorganized axonal proliferation in a nerve injury site, forming a non-neoplastic tumor containing glial cells, myofibroblasts, fibroblasts, and connective tissue. Usually, neuromas are clinically presented as small and oval nodules, manifesting neuralgic pain and touch hypersensitivity. When symptomatic, a neuroma can severely impact the quality of life and adequate treatment is of the utmost importance for reestablishing the patient's functionality. Usually, the preferred treatment is surgical excision of the tumor, but it's neither available for nor wanted by all patients. An alternative is pharmacotherapy using membrane-stabilizing drugs, such as anticonvulsants, corticosteroids, local anesthetic drugs, and non-steroidal anti-inflammatories. Unfortunately, a low proportion of patients achieve adequate symptom control with conservative treatment. Despite the few studies evaluating its effectiveness in this specific scenario, botulinum toxin (Btx) seems a promising alternative treatment. Btx therapy already shows evidence of effectiveness in the management of neuropathic pain and signs of its probable value in neuroma symptomatology control. **Final comments:** The presented case demonstrates the difficulties in obtaining adequate pain control in patients with neuroma, which highlights the necessity of combined pharmacological therapy and other treatment modalities, such as electrostimulation, nerve blockage, and Btx application. In that scenario, the usage of Btx in managing a symptomatic neuroma reached a satisfactory result, contributing to neuralgia reduction. Therefore, considering the difficulties of achieving adequate management for the condition, Btx likely is a valuable addition to the arsenal of drugs used in cases like that, despite the incipient literature currently available.

Effectiveness of botox (onabotulinumtoxin) in the treatment of migraines: a systematic review

Jonathan Vinicius da Silva Casarim[1], Anaclara Azalin Mattoso[1], Beatriz Cardoso Bálsamo[1], Carolina Pimentel Ladeira Gomes[1], Clara Rodrigues Oliveira[1], Lucas Vital Dias Gomide[1], Luiza Bianca Monteiro Castro[1], Nathalia Carolina Silva Moreira[1], Ana Paula Ferreira[1], Djalma Rabelo Ricardo[1]

[1]Faculdade de Ciências Médicas e da Saúde de Juiz de Fora, Juiz de Fora MG, Brazil.

Correspondence: Nathalia Carolina Silva Moreira; Email: nathalia.zsmoreira@gmail.com.

Background: Excessive use of medications such as analgesics, triptans and opioids is one of the main risks for transforming an episodic migraine into a chronic one. In this context, OnabotulinumtoxinA emerges as a promising alternative to prevent migraine chronification, acting to reduce the release of inflammatory neurotransmitters. **Objective:** To investigate the effectiveness of migraine treatment through the use of Botox (OnabotulinumtoxinA) through a systematic review. **Methods:** Controlled and randomized clinical trials published originally in English, over the last ten years, on humans were analyzed, using the National Library of Medicine (MedLine) database as a reference. The search for descriptors and terms used was carried out by consulting the Medical Subject Headings (MeSH), using its variations: "migraine disorders", "botox", "treatment". Studies involving men and women between 19 and 65 years of age diagnosed with chronic migraine were included. Studies that did not specifically use the substance OnabotulinumtoxinA, those with unclear or poorly described methods, and publications available only in the abstract were excluded. The PRISMA scale was used to systematize the scope of this review. **Results:** Initially, 973 studies were found. After applying the inclusion and exclusion criteria, nine articles were selected for the final analysis. In total, 1310 participants participated, 78.7% of whom were female, with an average age of 41.5±2.8 - 18 to 65 years old. Of the nine studies analyzed, eight indicated that the application of Botox reduced headache intensity, migraine frequency, and the intake of pain relief medications ($p<0.05$). Evidence points to the onset of treatment effects after 4 weeks ($p<0.05$). Furthermore, there was no difference in treatment between men and women ($p<0.05$). One of the studies showed that there was no benefit between the experimental group and

the control group (p=0.19). **Conclusion:** The systematic review demonstrated that migraine treatment with botox (OnabotulinumtoxinA) is effective in the long term. Furthermore, the use of Botox has been associated with a reduction in the frequency of migraines, the intensity of pain, and the consumption of medications for acute pain. Therefore, Botox can be an interesting alternative for migraine management, with significant implications for clinical practice and future research to better analyze these correlations.

Effectiveness of DBS as a treatment for Alzheimer's disease: meta-analysis

Julia Scaramal[1], Samuel Simis[2], Paulo Henrique Pires de Aguiar[2]

[1]Pontifícia Universidade Católica de São Paulo, Sorocaba SP, Brazil.
[2]Pontifícia Universidade Católica de São Paulo, São Paulo SP, Brazil.

Correspondence: Julia Scaramal Mello; Email: julia.scaramal71@gmail.com.

Background: Alzheimer's disease (AD) currently lacks a successful treatment despite being one of the most costly forms of dementia. Recently, deep brain stimulation (DBS) has emerged as a key treatment for diseases such as Parkinson's due to the neuromodulation achieved by targeting specific brain areas. Herrington's theory suggests that DBS can modify pathological pathways by modulating local neuronal activity. Consequently, some studies have investigated the effectiveness of DBS as a treatment for Alzheimer's disease. **Objective:** To perform a systematic review with meta-analyses to determine whether DBS is effective as a treatment for Alzheimer's disease based on the available literature. **Methods:** The search was conducted in PubMed and Cochrane using the terms "DBS" AND "Alzheimer". Articles were included if they met the eligibility criteria: published within the last 10 years, written in English, and discussing both DBS and Alzheimer's disease. Case reports and animal studies were excluded. **Results:** 17 articles were included after independent review by 2 reviewers. Of these, only 6 were clinical trials. Data extraction and analysis indicated that patients with mild AD showed less worsening on the ADAS-cog (Alzheimer's Disease Assessment Scale-cognitive subscale) following DBS. The most studied DBS targets were the fornix (66.67%), followed by the nucleus basalis of Meynert (33.34%) and the ventral capsule/ventral striatum (16.67%). Additionally, some studies reported an improvement in local metabolism as shown by PET imaging (66.67%). For the meta-analysis, the change from baseline for the ADAS-Cog scale shows no significant difference in correlation values (mean change of 5.8 points), and the studies exhibit low heterogeneity. Regarding the MMSE scale, the analysis revealed a confidence interval of -3 to +2 and a mean change from baseline of -0.54 points, indicating that DBS, over one year of stimulation, delayed the progression of Alzheimer's disease on that scale. **Conclusion:** Preliminary findings suggest that DBS may have some effectiveness in treating AD.

Background: Huntington's disease is an autosomal dominant neurological disorder that progressively affects cognition, motor function, and behavior. It is associated with a mutation in the HTT gene, responsible for encoding a protein involved in the development of the central nervous system. Neurodegeneration primarily affects striatal neurons, with characteristic symptoms including Huntington's chorea (involuntary muscle contractions), impaired attention and emotion recognition, apathy, irritability, and depression. Deep brain stimulation (DBS), for instance, has shown promise in treatment. This involves implanting electrodes that deliver electrical impulses to specific regions of the brain to modulate neural activity. **Objective:** To evaluate the efficacy and safety of DBS in treating Huntington's disease. **Methods:** A literature review was conducted focusing on studies published in the last 10 years investigating DBS application in Huntington's disease patients, using databases such as PubMed and the keywords "motor disorder," "Huntington's disease," and "deep stimulation." **Results:** Out of 27 studies, 4 were analyzed, indicating that DBS, particularly when targeted at the subthalamic nucleus and the internal globus pallidus, may lead to significant improvements in chorea, dystonia, and rigidity, which are debilitating motor symptoms in up to 80% of cases of Huntington's disease. Patients treated with DBS showed reduced severity scores of motor symptoms and improved daily functionality, suggesting that the intervention could enhance patients' quality of life. In addition to motor benefits, the review identified positive effects on psychiatric and cognitive symptoms associated with the disease. There were reports of improved emotional stability, reduced irritability and aggression, and in some cases, cognitive improvements. However, results are variable and depend on factors such as precise electrode placement, stimulation settings, and treatment duration. **Conclusion:** DBS appears to be a promising technique in treating Huntington's disease, potentially improving symptoms and restoring functional abilities in daily activities and routines of patients. Nonetheless, further studies are needed to analyze variability factors in the application of this aproach.

Effectiveness of dordaviprone in H3 K27M-mutant diffuse glioma: a systematic review and proportional meta-analysis

Felipe Araujo Gouhie[1], João Pedro Alves Rodrigues[1], Lucas Figueira Vieira[1], Caio Luiz Nazar Cunha[1]

[1]Universidade Federal de Uberlândia, Uberlândia MG, Brazil.

Correspondence: Felipe Araujo Gouhie; Email: felipeagouhie@gmail.com.

Background: Pediatric patients with Histone 3 (H3) K27M-mutant glioma have a poor prognosis despite current therapies. Dordaviprone is a first-in-class imipridone designed to treat resistant gliomas. However, there is a lack of literature studying the relationship between this new agent and this patient population. Therefore, the present study aims to explore the effects of Dordaviprone on the response rate in glioma-diagnosed patients. **Objective:** To systematically analyze existing literature to determine the efficacy of Dordaviprone (ONC201) in pediatric patients with H3 K27M-mutant glioma, comparing patients' states before and after treatment. **Methods:** We performed extensive literature searches using PubMed, Dimensions, and Cochrane databases. The assessed outcome was the overall response rate for patients undergoing Dordaviprone treatment. Statistical analysis was conducted using R Studio 4.3.1, and study heterogeneity was assessed using the I^2 index. **Results:** Five interventional studies were included in the analysis, comprising a total of 71 patients. The response rate with Dordaviprone in patients with H3 K27M-mutant diffuse glioma was 26.97% (95% CI 11.27% to 52.77%). **Conclusion:** The meta-analysis indicates a moderate overall response rate across the included studies, with significant heterogeneity observed among the results. This variability suggests differing study methodologies, population characteristics, or other contextual factors may influence the response rates.

Effectiveness of dual task in a combined training on quality of life and concern about falling in individuals with Parkinson's disease: randomized controlled trial

Alessandra Cattaneo Estrada Melanda[1], Rogério José de Souza[1], Amanda Lima Nogueira dos Anjos[1], Patrícia Gonçalves Broto da Silva[1], Milena Marie Matias Martins[2], Samuel Lidione da Silva[2], Ana Raquel Lindquist[3], Adriana Costa-Ribeiro[4], Suellen Mary Marinho dos Santos Andrade[4], Suhaila Mahmoud Smaili[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.
[2]Centro Universitário Filadélfia, Londrina PR, Brazil.
[3]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.
[4]Universidade Federal da Paraíba, João Pessoa PB, Brazil.

Correspondence: Amanda Lima Nogueira dos Anjos; Email: amandalima.nd@gmail.com.

Background: Studies on quality of life (QOL) and concern about falling in Parkinson's disease (PD) generally seek to understand how motor and non-motor symptoms impact these outcomes. As these are complex and multifactorial outcomes, it is necessary that QoL and concerns about falling take center stage in clinical studies, as well as which therapeutic approaches are most effective and whether there is additional benefit in combined therapies for their management. **Objective:** To verify the effectiveness of dual-task training (DT) combined with treadmill gait training and anodal transcranial direct current electrical stimulation (tDCS) on QoL and concern about falling in individuals with PD. **Methods:** This is a randomized controlled, blind clinical trial, consisting of 37 individuals with mild to moderate PD and without cognitive impairment, allocated into two groups: 1) Experimental Group (EG) that performed DT+ gait training in treadmill + anodal tDCS) and 2) Control Group (CG) that performed gait training on a treadmill + anodal tDCS). 12 intervention sessions were carried out, three times a week. DT training was based on the application of a protocol consisting of 3 levels, with 6 tasks at each level and with gradual evolution of complexity, applied during 18 minutes of walking training on the treadmill. The current was applied to the left dorsolateral prefrontal cortex, with an intensity of 2 mA, concomitantly with gait training. To assess quality of life, the Parkinson's Disease Questionnaire (PDQ 39) was used and concern about falling was assessed using

the International Falls Efficacy Scale (FES-I). Assessments were carried out at three moments: pre-intervention, post-intervention and after a 4-week follow-up period. The ANOVA tow-way of repeated measures was used to compare groups according to intervention, time and group vs time interaction. CAAE:45459521.6.1001. 5188. **Results:** There was a significant improvement in QoL in the EG (time effect) between the pre- and post-intervention moments, in the domains: mobility, emotional well-being and total PDQ-39 score; and between the pre-intervention and follow-up moments in the cognition domain and in the PDQ-39 total score. For the CG, there was an improvement between the pre- and post-intervention moments in the areas of body discomfort and total PDQ-39 score. No differences were observed between groups. However, there was an interaction of time vs. group, only for the cognition domain (p=0.015), with improvement between the pre- and follow-up moments, in favor of the EG (d=-0.71). Regarding the concern about falling measured by FES-I, there were no significant differences when considering the factor time, group and the interaction time vs. group. **Conclusion:** The addition of DT to a combined protocol of treadmill gait training and anodal tDCS was not effective in improving QoL and fear of falling in individuals with PD, with the exception of the cognition domain of the PDQ-39.

https://doi.org/10.5327/CBN240615

Effectiveness of GLP-1 receptor agonists in Parkinson's disease: a systematic review and meta-analysis

Yago Marcos Pessoa-Gonçalves[1], Victor Hugo Palhares Flávio Reis[1], Chamberttan Souza Desidério[1], Marlos Aureliano Dias-Sousa[2] , Carlo José Freire Oliveira[1], Rubens Gisbert Cury[3], Wellington Francisco Rodrigues[1]

[1]Universidade Federal do Triângulo Mineiro, Instituto de Ciências Biológicas e Naturais, Laboratório de Imunologia e Bioinformática, Uberaba MG, Brazil.
[2]Universidade Federal do Triângulo Mineiro, Hospital das Clínicas, Departamento de Neurologia, Uberaba MG, Brazil.
[3]Universidade de São Paulo, Departamento de Neurologia, Grupo de Distúrbios do Movimento, São Paulo SP, Brazil.

Correspondence: Yago Marcos Pessoa Gonçalves; Email: yagompg98@gmail.com.

Background: Animal studies have shown that Glucagon-like Peptide 1 (GLP-1) exerts neuroprotective effects on dopaminergic neurons in the substantia nigra and promotes functional recovery in animals. These preclinical findings suggest that GLP-1 receptor agonist drugs could be promising for treating Parkinson's disease (PD). **Objective:** To investigate the efficacy of GLP-1 agonists in the treatment of PD in randomized clinical trials. **Methods:** This study is a meta-analysis of randomized controlled trials that evaluated the efficacy of GLP-1 in PD. Embase, Pubmed and Cochrane were searched for trials published up to April 2024. Data were extracted from published trials and Cochrane tool for assessing risk of bias was employed. The extracted data were input into Review Manager (RevMan) 5.3 (Nordic Cochrane Centre, Denmark) to calculate the effect size. RevMan calculated as effect measure the mean difference with a 95% confidence interval (CI) using the inverse variance statistical method. **Results:** Regarding the risk of bias in each RCT, three were assessed to have an overall low risk of bias. The meta-analysis showed no significant overall improvement across all parts of the Movement Disorders Society Unified Parkinson's Disease Rating Scale (MDS-UPDRS). In Part I, which evaluates non-motor aspects of daily life, the MD between the intervention and control groups was -0.17; 95% CI -0.83, 0.50; p = 0.62. Part II assesses motor aspects of daily living and showed a MD of -1.67; 95% CI -3.42, 0.12; p=0.07. Part III, the motor scale, showed a MD of -1.75; 95% CI -3.54, 0.05; p=0.06 and finally the part IV, which assesses motor complications, showed a MD of -0.09; 95% CI -0.46, 0.28; p=0.64. However, subgroup analyses of studies with a minimum of 12 months of GLP-1 intervention revealed a significant improvement in motor symptoms (MDS-UPDRS part III) compared the control groups (MD -2.34; 95% CI -4.53, -0.14; p=0.04). In terms of levodopa equivalent daily dose, the MD between the intervention and control groups was not significantly different (MD, -42.11; 95% CI, -94.34, 10.11; p=0.11). Regarding cognitive functioning measured using the MATTIS-DRS2 scale, the MD between the intervention and control groups did not demonstrate a significant difference (MD, 1.60; 95% CI, -0.55, 3.75; p=0.14). In addition, no significant difference in quality of life (PDQ-39) was observed (MD -0.81; 95% CI -2.85, 1.23; p=0.44). **Conclusion:** GLP-1 interventions, particularly those lasting 12 months or longer, can effectively improve motor symptoms in PD patients as measured by MDS-UPDRS part III. These findings underscore the potential of GLP-1 in PD treatment and highlight the need for future clinical trials with larger numbers of participants and longer intervention periods. Such trials should focus on specific subgroups to better understand the full effect of GLP-1 agonists on PD management.

https://doi.org/10.5327/CBN240616

Effectivity of tafamidis in the control of neurological deficits in patients with familial amyloid polyneuropathy: a systematic review and meta analysis

Emanuela Freire Caetano Davi[1], Caio Levi Mendes Costa[1], Mariana Borges Falcão Costa[1], Leonardo Elias Araujo dos Santos[1], Francisco Duque de Paiva Giudice Junior[1], Leonardo José Rodrigues de Araújo Melo[1], Mariana Alcântara Tavares[1], João Marcelo Albuquerque Beserra de Sousa[1], João Pedro de Oliveira Gouveia Marcotti[1], Kauane Emilly Ribeiro Aureliano[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Emanuela Freire Caetano Davi; Email: emanueladavi@alu.ufc.br.

Background: Familial Amyloid Polyneuropathy (FAP) is a progressive hereditary disease caused by the deposition of the protein transthyretin (TTR) in peripheral nerves and other tissues. Tafamidis meglumine, a stabilizer of TTR deposition, is the only medication for the treatment of FAP available on SUS. **Objective:** to evaluate the impacts of Tafamidis meglumine on the neurological deterioration in patients with FAP measured by NISS-LL and its statistical significance. **Methods:** This systematic review was executed according to the PRISMA 4 checklist, with search on the databases PUBMED, Scielo and EMBASE with the terms "transthyretin familial amyloid polyneuropathy" AND "Tafamidis" in portuguese or english for controlled trials with "neurology" filter, extracting 65 studies. Eligibility criteria were analysis of effectiveness of isolated Tafamidis 20 mg on humans diagnosed with PAF on neurological presentations.The effect measures analyzed for outcome were the population, baseline and mean difference of NISS-LL points, confidence intervals and p value. Certainty of results was evaluated with the GRADE tool and evaluation of bias with the RoB2 guidelines. The software Rayyan was used to automate exclusion, discarding 41 studies, and after manual screening, 12 studies were selected for inclusion. **Results:** 5 studies offered data of randomized controlled trials with comparison of tafamidis vs placebo, and 6 open-label studies, including extensions. Total population across studies was 282 patients, mostly caucasian, not accounting for 1 study due to possible repetition. Meta Analysis of tafamidis vs placebo was done using the mean difference analysis on Jamovi. The group's baseline NISS-LL differences weren't statistically significant, with the mean baseline NISS-LL of Tafamidis groups being 8.7 and 9.22 in control groups. Slight but statistically significant favorability (p<0.001) was found to the Tafamidis group, with the mean difference of NISS-LL from baseline across studies being - 0.39 NISS-LL points (CI, -0.547, -0.251). Open-label long term follow-ups varied between 12-66 months with overall the median NISS-LL change was 2.67 points (CI, 1.75, 3.58). Mean change of NISS-LL from baseline was 1.65 points in 12 months (CI, 0.549, 2.74), 2.21 in 24 months (CI, 0.60, 3.81) and 6.33 points in 48 months (CI, 2.89, 9.76). In all studies, the previous placebo-group presented a higher NISS-LL baseline and smaller rate of response to medication, indicating considerable impact of earlier start to treatment in prognosis. **Conclusion:** This systematic review showed modest benefit to the use of Tafamidis to control neuropathy in FAP and evidence of sustainability in long term treatment. The review limitations were the scarcity of present literature, with possible publication bias, as well the limitations in studies due to limited population and drop out rates. Due to this, the certainty of results with the GRADE tool was considered as class III.

https://doi.org/10.5327/CBN240617

Effects of cannabigerol on neuroinflammation and spatial memory in mice with cerebral ischemia

José Guilherme Pinhatti Carrasco[1], Nathalia Akemi Kohara[1], Luis Fernando Fernandes Miranda[1], Rúbia Maria Monteiro Weffort de Oliveira[1], Cristiano Correia Bacarin[1]

[1]Universidade Estadual de Maringá, Maringá PR, Brazil

Correspondence: José Guilherme Pinhatti Carrasco; Email: joseguicarrasco@gmail.com.

Background: Cerebral ischemia is an important morbidity factor worldwide. The abrupt deprivation of cerebral blood flow, as occurs in stroke and reversible cardiac arrest, triggers a series of pathophysiological events such as excitotoxicity, oxidative stress and neuroinflammation that culminate in neuronal death and white matter injury. Despite its significance, there are still few pharmacological alternatives available for cerebral ischemia, making it necessary the development of therapeutic strategies that demonstrate good efficacy and safety. In this sense, cannabigerol (CBG), a non-psychoactive phytocannabinoid, has been studied for its anti-inflammatory and neuroprotective properties demonstrated in in vitro and in vivo studies. **Objective:** Evaluate the anti-inflammatory and anti-amnesic effects of different doses of CBG through an animal model of transient global cerebral ischemia (tGCI). **Methods:** For the experiments, male C57BL/6 mice were used. All experimental protocols were approved by the ethics committee. The tGCI was induced by bilateral common carotid artery occlusion (BCCAO) for 20 minutes. Animals in the sham group underwent the same procedure, but without occlusion. CBG, at doses of 1, 5 and 10 mg/kg, or vehicle were administered intraperitoneally for 7 days, with the first dose given 1 hour after BCCAO. The anti-amnesic effect of CBG was evaluated through the object location task (OLT), which was conducted between the 10th and 14th day after BCCAO, with intervals of 1, 4, and 24 hours to calculate the discrimination index D2 and observe memory retention. On the 15th day after the ischemic event, the animals were euthanized and their brains were removed and processed for immunohistochemical analyses. The anti-inflammatory effect of CBG was analyzed by quantifying the integrated optical density of Iba-1 in the CA1 and CA3 subfields of the hippocampus. **Results:** In the OLT, only at the 24-hour interval and in the group treated with CBG 1mg/kg, there was an increase in discrimination index D2 scores compared to the vehicle-treated group (p=0.0314), indicating an anti-amnesic effect of this dose on long-term memory. Regarding neuroinflammation, compared with the vehicle, the treatment with 1mg/kg of CBG attenuated the consequence of OBACC in the CA1 (p=0.0089) and CA3 (p=0.0235) subfields of the hippocampus, possibly due

to an anti-inflammatory effect. However, doses of 5 and 10 mg/kg of CBG did not modify the immunoreactivity of Iba-1 in the CA1 and CA3 subfields when compared with the BCCAO + Vehicle group (p>0.05). **Conclusion:** CBG exhibited anti-amnesic and anti-inflammatory effects after BCCAO at the dose of 1mg/kg, but not at doses of 5 and 10mg/kg, indicating a dose-dependent neuroprotective effect of the compound.

https://doi.org/10.5327/CBN240618

Effects of laser and ultrasound therapies on sciatic nerve axonotmesis: an experimental study

Natália Rebeca Alves de Araújo Karpejany[1], Danielle Cortellazzi Colonna Romano[2], Taianara Sampaio Reis[1], Juliana Do Nascimento Sousa[3], Vinícius Santana Vasconcelos[3], Allan Dellon da Silva[4], Antônio Luiz Martins Maia Filho[4], Wellington dos Santos Alves[4], Danniel Cabral Leão Ferreira[4], Ester Laignier Barroso[5]

Correspondence: Natália Rebeca Alves de Araújo Karpejany; Email: nataliarebeca2607@gmail.com.

Background: Peripheral nerve injuries affect sensory and motor functions, with the sciatic nerve is commonly affected. Axonotmesis is a type of nerve injury in which the connective tissue surrounding the nerve's axons remains intact and represents the majority of cases of peripheral nerve injuries. Peripheral nerve recovery can be optimized by Low-Level Laser Therapy (LLLT), known for its bio-photomodulatory effect capable of accelerating the axonal regeneration process. Therapeutic ultrasound (UST) emits waves that improve blood flow and oxygen exchange, increasing cellular metabolism. This therapy can be applied to help reduce inflammatory processes and promote peripheral nerve regeneration by increasing nerve fiber density and stimulating axoplasm production. **Objective:** To analyze the effects of LLLT and UST on the regeneration process after axonotmetic injury of the sciatic nerve in Rattus norvegicus. **Methods:** This experimental, analytical, quantitative study investigated 30 healthy male rats (Rattus norvegicus). Rats were randomly divided into five groups: G1 (positive control, no lesion or treatment), G2 (negative control, with lesion but no treatment), G3 (lesion and treated with low-level laser therapy, LLLT), G4 (lesion and treated with ultrasound therapy, UST). All animals were anesthetized and a sciatic nerve injury was induced. G1 received no treatment, G2 received no treatment post-lesion, G3 received LLLT daily for 17 days, and G4 received UST daily for 17 days. Gait was assessed preoperatively, on postoperative days 1, 7, 14, and 21 using the Sciatic Functional Index (SFI) derived from footprint analysis. Data were analyzed using ANOVA and Tukey's test, with p<0.05 considered significant. **Results:** Preoperatively, all groups had Sciatic Functional Index (SFI) values near 0, indicating normal gait. Significant differences were observed between the lesioned groups and the positive control on postoperative days 1 and 7 (P<0.05). By day 14, only the ultrasound group differed significantly from the negative control (P=0.010271293). By day 21, no significant differences in gait were found between treated groups and controls. The laser group showed significant differences preoperatively and on all postoperative days, but did not fully recover by day 21. The ultrasound group showed significant recovery by day 14 (P=0.081191726). **Conclusion:** Intergroup analysis showed no practical difference between low-level laser therapy and therapeutic ultrasound treatment. But, when comparing the different treatment phases within the same experimental group (intragroup analysis), only therapeutic ultrasound showed better results in the recovery of gait and motor function of the crushed sciatic nerve on the 14th postoperative day. It is suggested that research on the subject continue to define analysis protocols and methodologies for future studies comparing the effects of low-level laser therapy and therapeutic ultrasound for nerve regeneration.

Effects of melatonin use in children with sleep disorders: a systematic review

Ana Luiza Rossetto[1], Samyra Roberta Assis Souza[1], Maria Gabriella Vido Dutra[1], Maria Paula Vitalino Faria da Silva[1], Leila Maria Guissoni Campos[1]

[1]Universidade de Marília, Marília SP, Brazil.

Correspondence: Ana Luiza Rossetto; Email: rossettoanaluiza23@gmail.com.

Background: Sleep is a functional state that involves important neurological processes. It is known that prolonged sleep deprivation can result in serious physical and behavioral impairments, as well as metabolic and immunological changes. In children, the repercussion of sleep disturbances can be characterized by reduced performance and learning. When the biological causes are related to endocrine problems, such as abnormal production of the melatonin hormone, the use of exogenous melatonin becomes an option for treating sleep disorders. **Objective:** To analyse the effect of exogenous melatonin use in children as a form of treatment for sleep disorders. **Methods:** A systematic review was conducted by selecting studies from the BVS-PubMed database published between 2019 and 2024. A total of 238 studies were found, of which 42 were selected for analysis. Articles in English and/or Portuguese that addressed the effects of pharmacological use of melatonin in children with sleep disorders were used. The descriptors used were "Sleep" AND "Melatonin" AND "Children" AND "Sleep disorders". Articles that did not fit the inclusion criteria, such as animal studies, narrative reviews, and those unrelated to the review topic, were excluded. **Results:** The use of melatonin was indicated as a treatment method in different groups of children, such as those with neurodevelopmental disorders, intellectual disabilities, learning and motor disorders, communication disorders, and attention deficit disorder. A decreased sleep onset latency was observed, along with improvement in morning temperament, irritability, hyperactivity, and inappropriate speech. When melatonin use was combined with sleep hygiene (fixed bedtime routine, bedtime stories, avoiding light at night, calming music, among others), significant improvements were observed in sleep onset, anxiety, delayed sleep onset, sleep duration, night awakenings, and parasomnias, compared to the placebo group. Side effects were observed in a few cases, with mild symptoms characterized by headaches. **Conclusion:** The use of melatonin may represent an improvement for sleep disturbances; however, when combined with sleep hygiene, the results appear to be more promising. The quantity of melatonin - timing/dosage should be carefully evaluated to avoid possible side effects.

Effects of mental practice on fog in people with Parkinson's disease: a randomized clinical trial

Paloma Rodrigues da Silva[1], Karina Yumi Takayama Honda[1], Isaira Almeida Pereira da Silva Nascimento[1], Katia Cirilo Costa Nobrega[1], Nathalia de Brito Pereira[1], Thayane Habache Barolli[1], Maria Elisa Pimentel Piemonte[1]

[1]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Paloma Rodrigues da Silva; Email: paloma.rsilva@usp.br.

Background: Freezing of gait (FOG) significantly impairs the quality of life in Parkinson's disease (PD). Mental practice (MP) is an emerging field in neurorehabilitation and Dynamic Neuro-Cognitive Imagery (NCI) is a new approach that combines MP with physical practice (PP). Despite limited research on NCI-based interventions, they are considered safe and effective for remote administration in individuals with PD. **Objective:** To compare the effects of an experimental intervention (EI) based on NCI with a control intervention (CI) of equal volume and intensity, differing only in mental practice components, on PD-related FOG. **Methods:** A randomized, controlled, double-blind trial with 23 participants, mean age 54, H&Y stages II/III, and about 17 years of schooling. Inclusion criteria included diagnosis of idiopathic PD, use of dopaminergic medication, at least one episode of FOG per day, ambulation without any orthosis or assistive device at home, internet access, and agreement to participate. Individuals with neurological, cardiovascular, or respiratory disorders, uncorrected visual or auditory impairments, severe cognitive impairments affecting verbal instruction comprehension, or inability to perform motor imagery during the Kinesthetic and Visual Imagery Questionnaire-20 (KVIQ-20) application were excluded. Assessments and interventions were remotely conducted via video conferencing, with each participant undergoing 10 training sessions lasting 45 minutes. All participants were assessed before (BT), after (AF), and 60 days post-training as a follow-up (FU). FOG frequency, intensity, and impact on functionality were assessed using the New Freezing of Gait Questionnaire (NFOG), Rapid Turns Test, and Percentage of Time with FOG (%FOG).The results were analyzed by ANOVA for repeated measures considering group and evaluation as factors. **Results:** Nineteen participants completed training and reassessment. The remote study protocol was feasible. Both groups exhibited reduced NFOG scores (p<0.0004), fewer FOG occurrences during the Rapid Turns Test, and a decrease in %FOG (p<0.036). **Conclusion:** The study found both interventions positively impacted FOG episodes, motor aspects, functionality, and quality of life, with no significant difference between groups. This suggests remote MP delivery could be beneficial in reducing FOG's impact on PD patients' daily lives.

Effects of neuromodulation in patients with multiple sclerosis: a systematic review

Cicera Simplicio Machado Leandro, Maria Lucia Vellutini Pimentel[1], Letícia Fezer de Souza Mansur[1]

[1]Universidade do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.
[2]Santa Casa da Misericordia.

Correspondence: Cicera Simplicio Machado Leandro; Email: ciceramachado.medicina@hotmail.com.

Background: Multiple sclerosis (MS) is an immune-mediated and demyelinating disease that affects the young population and is more prevalent in women. Some studies show that due to neuroplasticity, neural reorganization can occur in the case of nerve injuries, such as multiple sclerosis. For this reason, therapeutic interventions that stimulate the neuroplastic process are increasingly indicated. It is known that transcranial neurostimulation is one of these interventions consisting of safe, well-tolerated and low-cost techniques, capable of stimulating the affected cortical region and promoting motor and functional benefits that can induce gains in rehabilitation with the advantages of being non-invasive, excellent tolerability and can be associated with other treatments. **Objective:** To analyze the evidence regarding the use of

neurostimulation in patients with sclerosis and its benefits in minimizing damage resulting from outbreaks, as well as in rehabilitation therapy. **Methods:** A literature review was carried out in three stages: elaboration of the research question, search for scientific articles in the Pubmed database, Google scholar and critical analysis of the included articles. The search was carried out between October 12, 2023 and December 5, 2023. 70 articles were identified, 11 of which were included in the qualitative synthesis. **Results:** Neuromodulation combined with physical therapies and conventional treatments is capable of promoting improvements in the quality of life and functionality of patients with MS, especially when started in the early stages of the disease. **Conclusion:** More studies are needed to better understand the relationship between neuromodulation and the genesis of MS. Furthermore, the limited number of articles found in the literature demonstrates the need for more studies to be carried out, with larger samples and specific protocols.

Effects of non-invasive neuromodulation on food cravings and executive functions in health professionals

Marta Maria da Silva Lira Batista[1], Marcela Lima Silagi Siqueira[2], Maria Do Carmo de Carvalho e Martins[3], Lara Liane de Queiroz Pereira

[1]Universidade Federal do Piauí, Hospital Universitário, Teresina PI, Brazil.
[2]Universidade Federal de São Paulo, São Paulo SP, Brazil.
[3]Universidade Federal do Piauí, Teresina PI, Brazil.

Correspondence: Marta Maria da Silva Lira Batista; Email: fonointensivista@gmail.com.

Background: Food cravings are common in individuals with and without eating disorders, especially for palatable and highly processed foods. Several factors, including blood sugar levels, hormonal variations and emotional state, influence eating decisions, mediated by neural networks associated with self-regulation, such as the dorsolateral prefrontal cortex (DLPFC). Changes in self-regulation can inhibit unwanted memories, facilitating eating goals. Studies in animal models show that deficiencies in memory inhibition increase food impulsivity and weight gain. Cortical direct current stimulation modulates neural activity and can reduce food cravings and inflammatory markers. This pioneering study also investigates chewing behavior as an analysis variable. **Objective:** To evaluate the effects of neuromodulation on food cravings, chewing patterns, brain executive functions and markers of inflammation/antioxidant activity before and after stimulation. **Methods:** A randomized, double-blind, parallel clinical trial was conducted with healthcare professionals from a University Hospital. Participants were excluded based on specific criteria and randomized to receive active or sham tDCS for 10 sessions. Assessments included food craving questionnaires, cognitive tests, biochemical and functional chewing analysis. tDCS was applied to the dorsolateral prefrontal cortex, with the aims of modulating neural activity and reducing food cravings. The study followed ethical guidelines and was registered on ClinicalTrials.com (NCT05046145), in line with CONSORT standards. **Results:** In this randomized, double-blind clinical trial, 36 participants were evaluated after receiving active or sham tDCS. They were predominantly women (63.2% in the tDCS group; 64.7% in the sham group), with an average age of 31 to 40 years, high educational level and overweight (52.6% in the tDCS group; 35.3% in the sham group). The intervention promoted a significant reduction in food cravings, especially for fatty foods and sweets, and improved executive functions such as working memory and cognitive inhibition. There was no impact on the biochemical parameters of inflammation and antioxidant activity. The tDCS may be a promising tool to modulate eating behaviors and executive functions in populations with specific characteristics, although a complete understanding of the biological, cognitive and sociodemographic interactions remains challenging. **Conclusion:** tDCS reduces food cravings and reaction time/execution of executive functions, without affecting brain biochemistry. More interdisciplinary studies are needed to understand impacts on the stomatoglossognathic system.

Effects of trans-spinal direct current stimulation combined with motor training in traumatic spinal cord injuries: a case study

Caroline Rodrigues Osawa[1], Pedro Henrique Sousa de Andrade[1], Felipe Tumietto Domingues[1], Gustavo José Luvizutto[1]

[1]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Caroline Rodrigues Osawa; Email: fisiocarolineosawa@gmail.com.

Case presentation: A.L.B a 50-year-old married male from Uberaba, MG. In January 2020, he suffered a stab wound in the dorsal region, injuring the spinal cord at the T3 vertebra level (neurological level T1), resulting in a condition of sensory-motor paraplegia. The volunteer underwent a motor training (MT) protocol combined with cathodal trans-spinal direct current stimulation (tsDCS) at an intensity of 2mA, three times a week for 10 weeks (December 2023 to February 2024). The cathode was positioned at the lowest motor level, as determined by the ASIA International Standards for Neurological Classification of Spinal Cord Injury (ISNCSCI), and the anode was placed in the posterior deltoid region. The sessions lasted a total of 45 minutes, with the initial 20 minutes consisting of MT + tsDCS and the remaining 25 minutes of MT alone. **Discussion:** The evaluation considered the domains of the International Classification of Functioning, corresponding to electromyography (EMG) analysis for function, the Trunk Impairment Scale (TIS) for activity, and the Spinal Cord Independence Measure (SCIM) for participation. In the EMG, the volunteer showed no difference in peak contraction of the muscles evaluated (biceps brachii, triceps brachii, radial flexor and extensor of the wrist, rectus femoris, anterior tibialis, and lateral gastrocnemius). However, there was a 19% increase in TIS and a 5% increase in SCIM. **Final comments:** It can be inferred that functional changes are not observed due to the time since injury (4 years); however, even in this chronic phase, we can note benefits in the domains of activity and participation, highlighting the potential for improvement with trans-spinal stimulation in functionality and, consequently, the quality of life for these individuals.

Background: INPH, the most common form of hydrocephalus in adults, is a syndrome that can potentially be reversed by cerebrospinal fluid shunt. It is marked by a set of complex symptoms, with unexplained symmetric gait disturbance being the primary symptom. LPS is one of the recommended shunt types for iNPH. However, the benefits of LPS are conflicting in the literature. **Objective:** We sought to perform a Systematic Review and Meta-analysis to assess the functional outcomes of Lumboperitoneal shunt (LPS) in patients ≥60 years of age with Idiopathic Normal Pressure Hydrocephalus (iNPH). **Methods:** MEDLINE, Embase, and Cochrane were searched for RCTs and prospective studies that directly compared patients before and after LPS surgery. Studies were analyzed based on the following endpoints: Mini-Mental State Exam (MMSE), Evan's Index, subdural hematoma events, infection, and shunt malfunction. Data was examined using the Mantel-Haenszel method and 95% confidence intervals (CIs). Heterogeneity was assessed using I2 statistics. The Baujat plot was used to estimate the individual heterogeneity of each included study. **Results:** Seven studies and 809 patients were included. Evan's Index was significantly better in the post-shunt group (MD 0.0272; 95% CI 0.0012-0.0533; p=0.04; I2=75%). MMSE (MD −0.5656; 95% CI −1.3166-0.1854; p=0.1; I2=0%), subdural hematoma events (Proportion 0.05; 95% CI 0.03-0.07; p=0.39; I2=1%), shunt infection (Proportion 0.01; 95% CI 0.00-0.03; p=0.41; I2=0%), and shunt malfunction (Proportion 0.03; 95% CI 0.02-0.05; p=0.85; I2=0%) endpoints did not show any statistically significant difference between groups. **Conclusion:** This meta-analysis suggests that LPS may be an efficient intervention for iNPH in patients ≥60 years old, given the decrease in the Evan Index, a scale that measures the degree of ventricular distention.

https://doi.org/10.5327/CBN240625

Efficacy and safety of argatroban in treatment of acute ischemic stroke in patients not receiving endovascular treatment: a systematic review and meta-analysis

Pedro Henrique Gorri Custódio de Melo Brites[1], João Marcelo Lorga Carnielli[1], Danilo Augusto Fernandes Moura[1], Guilherme Augusto Guimarães Resende[1], Julia Favaro Brenny[2], Maria Clara de Mattos Mira[1], Fernanda Peres Tomazoli[1], Camilla Stringuetta Gallo[3], João Felipe Hermann Costa Scheidt[3]

[1]Universidade Estadual de Maringá, Maringá PR, Brazil.
[2]Universidade Estadual de Londrina, Londrina PR, Brazil.
[3]Hospital Evangélico de Londrina, Londrina PR, Brazil.

Correspondence: Pedro Henrique Gorri Custódio de Melo Brites; Email: pedro@brites.srv.br.

Background: Globally, stroke is a major cause of death and disability. Argatroban, a direct thrombin inhibitor, is promising for the treatment and prevention of acute ischemic stroke. Known for its anticoagulant properties, especially in patients with heparin-induced thrombocytopenia, its role in managing acute ischemic stroke is of great interest. **Objective:** This meta-analysis assesses the effectiveness and safety of argatroban in the treatment of acute ischemic stroke. **Methods:** We conducted a comprehensive search of PubMed, Embase, and Cochrane Library for studies on argatroban in acute ischemic stroke treatment, covering literature up to April 12, 2024. Only randomized controlled trials and observational studies

were considered. Reviews, case reports, preclinical studies, and single-arm studies were excluded to focus on robust clinical data, as well articles that the control group had mechanical thrombolysis. Meta-analyses were performed using a random-effects model, pooling data as odds ratios (OR) with 95% confidence intervals (CI), considering p-values <0.05 as statistically significant. High heterogeneity was noted for I2 values over 50%. Safety outcomes included rates of intracranial hemorrhage (ICH), major bleeding (mB), and mortality. The main efficacy outcome measured was the modified Rankin Scale (mRS) score at 3 months. Another outcome investigated was early neurological deterioration (END), defined as a decrease in NIIHS score in a short period of time. **Results:** The systematic review included 17 studies, among them 7 randomized clinical trials. The meta-analysis revealed that argatroban does not significantly increase the risk of ICH (OR 1.10, 95% CI 0.76-1.59, p=0.60, I2=0%), major bleeding (OR 1.39, 95% CI 0.93-2.03, p=0.11, I2=0%), or mortality (OR 1.11, 95% CI 0.61-2.00, p=0.74, I2=3%). Furthermore, the argatroban-treated patients showed a significant improvement in achieving mRS scores of 0-1 (OR 1.58, 95% CI 1.08-2.33, p=0.02, I2=70%), 0-2 (OR 1.21, CI 1.04-1.42, p=0.02, I2=0%). In addition, the argatroban group has shown significant reduction in the rates of early neurological deterioration (OR 0.43, CI 0.29-0.64, p<0.0001, I2=23%). **Conclusion:** Argatroban treatment in acute ischemic stroke demonstrates safety comparable to standard treatments, with low rates of serious adverse effects like intracranial or major bleeding. It also significantly enhances functional outcomes as measured by mRS scores and decreased rates of END, indicating better prognosis. Further subgroup analyses may help reduce heterogeneity in mRS score outcomes, supporting the efficacy and safety of argatroban in this context.

Efficacy and safety of atogepant for migraine prevention: a systematic review and meta-analysis of randomized controlled trials

Kaike Eduardo da Silva Lobo[1], Marcus Paulo Oliveira Lopes[1], João Lucas Lalor Tavares[1], Arthur Moraes dos Santos[1], Felipe Moraes Costa[1], Flavio Lobo Altieri[1], Arley Nikson Oliveira Barreto[1], Ruan Pablo da Silva Gomes[1], Leonardo Bastos Santos[1], Leonardo Aguiar dos Santos[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Marcus Paulo Oliveira Lopes; Email: marcus.polopes@aluno.uepa.br.

Background: Migraine is one of the most common neurological disorders, with an estimated prevalence of 15% of the population, affecting more than one billion people worldwide. Atogepant is an oral, small-molecule, calcitonin gene-related peptide receptor antagonist that was approved in 2021 by the US Food and Drug Administration for the preventive treatment of episodic migraine. However, its efficacy and safety are still uncertain. **Objective:** We performed a systematic review and meta-analysis to evaluate the efficacy and safety of atogepant for the preventive treatment of migraine. **Methods:** We searched MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials and Web of Science from inception to June 2024 using "Atogepant", "MK-8031", "AGN-241689" and "migraine" search terms. Eligible articles were randomized clinical trials that showed efficacy and safety outcomes, such as changes from baseline in monthly migraine days and the incidence of adverse events (AEs), in patients who underwent migraine prevention with atogepant or placebo. Two independent reviewers extracted the data. Mean difference (MD) and risk ratio (RR) with 95% confidence intervals (95% CIs) were estimated. **Results:** Four studies were eligible for inclusion. The statistical analysis focused on the once-daily 60 mg dose of atogepant, as this dosage was the only one evaluated by at least three studies. In the patients who received atogepant, there was a significant decrease in monthly migraine days (MD -1.62; 95% CI -2.28, -0.96; p=0.00001; I'=100%), monthly headache days (MD -1.70; 95% CI -2.14, -1.26; p=0.00001; I'=100%) and monthly acute medication use days (MD -1.82; 95% CI -2.36, -1.29; p=0.00001; I'=100%) compared to the placebo group. The percentage of patients who achieved at least a 50% reduction from baseline in the 3-month average of monthly migraine days was significantly higher in the atogepant group (50.6% vs 28.4%; RR 1.82; 95% CI 1.34, 2.48; p=0.0001; I'=82%). In terms of safety endpoints, there was not a statistically significant difference between groups in treatment-emergent AEs (57.1% vs 52.1%; RR 1.09; 95% CI 0.93, 1.26; p=0.28; I'=65%), treatment-emergent serious AEs (1.55% vs 0.85%; RR 1.60; 95% CI 0.51, 5.08; p= 0.42; I'= 19%) and treatment discontinuation due to AEs (2.87% vs 2.8%; RR 1.02; 95% CI 0.58, 1.80; p=0.94; I'=0%). However, the treatment-related AEs (19.5% vs 11.9%; RR 1.64; 95% CI 1.25, 2.15; p=0.0004; I'=26%) were significantly increased in the atogepant group. **Conclusion:** Atogepant 60mg once a day was safe and showed significant reduction in mean monthly migraine days compared with placebo. However, further research is needed to evaluate different dosages and fully understand its safety profile.

Background: Chronic Migraine (CM) is a disabling neurological disorder classified as a complication of migraine. Patients with CM experience headaches on 15 or more days per month in at least three consecutive months. Despites the range of therapeutic treatments, in some cases current treatments often have limited efficacy and intolerable adverse events, highlighting gaps in prophylactic treatment options. OnabotulinumtoxinA (BoNT-A), a purified protein that blocks acetylcholine release from presynaptic neurons and inhibits muscle contractions, has shown pain relief in various conditions, including migraine. Clinical trials suggest that BoNT-A may be an effective and safe prophylactic medication for treating migraines and other headache disorders. **Objective:** To evaluate the efficacy and safety of BT-A in the treatment of chronic migraine through a systematic review and meta-analysis. **Methods:** The literature search was performed using PubMed, Scopus, and Web of Science databases. The inclusion criteria consisted of randomized controlled trials that evaluated the use of BoNT-A in patients diagnosed with chronic migraine, comparing it to a placebo group. Studies were screened and selected based on relevance, and data were extracted by independent reviewers. The primary outcomes were the reduction in the number of headache days and the incidence of adverse events. All statistical analyses were performed using the RStudio (version 4.3.2). **Results:** A total of 11 studies and 3.617 patients were included, with 2.092 (57.84%) receiving botulinum toxin type A (BoNT-A) and 1.525 (42.16%) in the placebo group. BT-A therapy was associated with a significant reduction in the number of headache days per month in the BoNT-A group (odds ratio: 0.89; 95% CI: 0.54 to 1.49; P<0.01; I^2=72%), suggesting that BoNT-A is effective in reducing the frequency of chronic migraine episodes. Adverse events were reported more frequently in the BT-A group compared to the placebo group (odds ratio: 0.96; 95% CI: 0.37 to 2.48; P<0.01; I^2=97%). Common adverse effects included neck pain, muscle weakness, and injection site pain. The high heterogeneity indicates variability in the reported adverse effects among different studies. **Conclusion:** The results of our study suggest that the therapy with BT-A is demonstrated a significant reduction in headache days per month compared to the placebo group. However, BT-A treatment was also associated with a higher incidence of adverse effects. Overall, BT-A appears to be a promising prophylactic treatment for chronic migraine, balancing its beneficial reduction in headache frequency against the consideration of its adverse effects.

https://doi.org/10.5327/CBN240628

Efficacy and safety of galcanezumab for cluster headache preventive treatment: a systematic review and meta-analysis

Marina Barbosa da Silva[1], Domenica Baroni Coelho de Oliveira Ferreira[2], Cristian David Mendieta Barrera[3], Lívia Aguiar Nogueira Rosa[4], Nathalia Moraes Figueiredo[5]

Background: Galcanezumab is a monoclonal antibody targeting the calcitonin gene-related peptide (CGRP) pathway and represents the latest disease-specific and mechanism-based therapeutic option for cluster headache (CH). **Objective:** We performed a systematic review and meta-analysis to evaluate the efficacy and safety of galcanezumab for CH. **Methods:** We searched PubMed, Embase, and Cochrane Library for studies implementing galcanezumab for episodic and chronic CH, with no language restrictions. We followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guideline. The primary outcome was efficacy, defined by a reduction from the baseline of at least 50% in the weekly frequency of cluster headache attacks and the Patient Global Impression of Improvement scale (PGI-I). Secondary outcomes included treatment-emergent adverse events (TEAEs) and serious adverse events (SAEs). **Results:** A total of 504 patients were included from 6 studies, of which 2 were RCTs. The follow-up period ranged from 3 weeks to 15 months. The mean age was 44.4±10.2 years, with 24.4% female patients. Overall efficacy was 76.0% (95% CI 0.67 - 0.85), TEAEs were observed in 48.0% of patients (95% CI 0.25 - 0.72), and the most common were nasopharyngitis, local injection pain, and local injection swelling. TEAEs were however considerably higher within the 300 mg dose group compared with the 240 mg dose group, 80.0% (95% CI 0.65 - 0.87) versus 28.0% (95% CI 0.12 - 0.47), respectively. **Conclusion:** This meta-analysis suggests that galcanezumab is effective in reducing the number of CH attacks and can be considered a safe medication.

Efficacy and safety of hematopoietic stem cells transplantation in Krabbe disease: a systematic review

Leonardo José Rodrigues de Araújo Melo[1], Francisco Luciano Honório Barreto Cavalcante[1], Lucas Soares Radtke[1], Letícia da Costa Rios[1], Paulo Wendel Moura de Souza[1], Pedro Vitor Ferreira Rodrigues[1], Leonardo Elias Araujo dos Santos[1], Pedro Lucas Grangeiro de Sá Barreto Lima[1], Anderson Rodrigues Brandão de Paiva[2], Paulo Ribeiro Nóbrega[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.
[2]Mendelics Análise Genômica, São Paulo SP, Brazil.

Correspondence: Leonardo José Rodrigues de Araújo Melo; Email: lleonardomello98@alu.ufc.br.

Background: Krabbe disease (KD) is a rare autosomal recessive leukodystrophy caused by deficiency of β-galactocerebrosidase (GALC) that leads to accumulation of toxic metabolites, causing progressive loss of myelin in the central nervous system and peripheral nerves, resulting in severe motor and cognitive impairment. Hematopoietic Stem Cells transplantation (HSCT) is one of the most promising therapies for infantile-onset KD (IKD). **Objective:** To investigate the efficacy and safety of HSCT for neurological improvement in IKD. **Methods:** A systematic literature search was conducted on PubMed and Web of Science platforms, following PRISMA protocol, using DeCS/MeSH descriptors "Krabbe disease" or "globoid cell leukodystrophy" and "Transplant" and "Hematopoietic Stem Cells". The inclusion criteria were cohorts or clinical trials published in English in which patients with IKD were submitted to HSCT therapy. Reviews, case reports or animal studies were excluded.The efficacy was measured by survival rates (SR) and neurological improvement after HSTC. Articles were analyzed by two blind observers using the Rayyan AI platform, with divergences analyzed by a third independent individual. Initially, 220 papers on the subject were obtained. **Results:** Twelve articles met the inclusion criteria, including 10 cohort studies and 2 clinical trials, totaling 181 patients, who were divided into two groups: symptomatic (SS) and asymptomatic (AS) patients at the moment of HSCT, with average follow-up time ranging from 6 months to 12 years. The SR at the end of follow-up varied from 69 % to 100% for AS and 42% to 100% for SS, higher rates than previously reported historical controls. Neurological improvement was assessed clinically and using scales; such as BAYLEY III, which indicated a greater proportion of neurodevelopmental milestones than historical controls in AS group compared to the SS group, with gross motor components showing little change after HSCT in both groups.It was reported that patients with early HSTC, especially before 1 month of age, had better neurological outcomes. GALC levels were restored after HSCT in most patients, but were not associated with clinical improvement in SS patients. The most common adverse events were graft-versus-host disease and urinary and pulmonary infections **Conclusion:** HSTC for IKD proves to be an effective therapy, with acceptable adverse effects, possibly better when performed earlier in patients with evidence of the disease but without symptoms. This may lead to longer survival times, greater chances of achieving neurodevelopmental milestones, although evidence is less clear in terms of improvement of gross motor skills. Study limitations include significant heterogeneity in the forms of neurological improvement assessment across the articles. Further studies with more standardized methodologies are needed to more accurately evaluate HSTC for IKD.

Background: Hereditary transthyretin amyloidosis is a rare and progressive peripheral sensorimotor neuropathy. Inotersen, an antisense oligonucleotide inhibitor and Eplontersen, a transthyretin antisense oligonucleotide, are both approved by the Food and Drug Administration for the treatment of this condition. However, the efficacy of both has not yet been tested in a meta-analysis **Objective:** We sought to assess the safety and efficacy of Inotersen and Eplontersen among adult patients. **Methods:** We searched Pubmed, Scopus, and Web of Science databases for randomized controlled trials that investigated Inotersen and Eplontersen in comparison with a placebo group. A random-effects model was employed to compute the mean difference (MD) with a 95% confidence interval (CI). Statistical analysis was performed using R software 4.3.1. **Results:** In the two included studies, involving 308 patients, the follow-up period completed 66 weeks and the adjusted mean for the modified Neuropathy Impairment Score+7 composite score reached a statistically significant difference: (MRAW 2.58 [95% CI, −3.27 to 8.44]; P<0.01), trending towards the Eplonserten treatment. Moreover, Norfolk Quality of Life–Diabetic Neuropathy (MRAW −3.25 [95% CI, −11.28 to 4.77]; P<0.01) and Short Form 36 score (MRAW 0.73 [95% CI, 0.10 to 1.36]; P=0.26) also presented significantly better results for Eplonserten. **Conclusion:** In this meta-analysis of two studies, consistent results suggest that Inotersen and Eplontersen both associated with beneficial outcomes and a improved quality of life in patients with hereditary transthyretin amyloidosis

Efficacy and safety of mechanical thrombectomy in posterior circulation ischemic strokes: a systematic review

Rayanne Pereira Mendes[1], Atilio Gomes Romani[1], Saulo Barros Teixeira[1]

[1]Faculdade de Medicina do ABC, Santo André SP, Brazil.

Correspondence: Rayanne Pereira Mendes; Email: rayannepmendes@gmail.com.

Background: Posterior circulation ischemic strokes, caused by the occlusion of vertebral and basilar arteries, comprise 20% of all ischemic strokes and have higher morbidity and mortality than anterior circulation strokes. Mechanical thrombectomy (MT) is effective for large vessel occlusions, supported by guidelines based on randomized clinical trials. However, its benefits in posterior circulation were often not covered in most of these studies. **Objective:** To evaluate the efficacy and safety of mechanical thrombectomy in posterior circulation ischemic strokes. **Methods:** A systematic review synthesized results from 2021-2022 clinical trials on MT efficacy and safety in posterior circulation. Data was extracted from PubMed, with inclusion criteria of high-level evidence and recent randomized clinical trials, excluding studies that did not meet these standards. **Results:** The studies evaluate the efficacy of MT compared to the Best Medical Treatment (BMT), which consists of anticoagulants, antithrombotics, or thrombolysis in eligible cases. Primary outcomes analyzed included rates of successful recanalization, functional independence (modified Rankin scale score of 0-2 at 90 days), and safety outcomes, including symptomatic intracranial hemorrhage and mortality. In a trial conducted in 23 countries with 300 patients, 44.2% of patients undergoing MT within 6 hours of basilar artery ischemic stroke onset had a favorable functional outcome versus 37.7% in the BMT group at 90-day follow-up (CI: 0.92 to 1.50). Mortality was 38.3% in the endovascular group and 43.2% in the medical care group (P=0.29). Symptomatic intracranial hemorrhage was 4.5% in the MT group versus 0.7% in the BMT group. In another trial that included 217 randomized patients, 46% of patients undergoing MT within 6 to 24 hours of symptom onset achieved functional independence at 90 days versus 24% in the BMT group (P<0.00). Symptomatic intracranial hemorrhage was 6% in the MT group versus 1% in the BMT group, with 90-day mortality rates of 31% versus 42%, respectively. In a prospective multicenter study conducted with 2134 patients from 2017 to 2021, 82% of patients in the endovascular group achieved successful recanalization. There was a higher rate of functional independence at 90 days in the MT group (44% versus 25% in the BMT group) and a lower mortality rate in the MT group (36.9% versus 47.5%) with an absolute risk difference of −10.3%. However, there was a higher rate of symptomatic intracranial hemorrhage in the MT group (5.2% versus 0.9%) with an absolute risk difference of 4.5%. **Conclusion:** The studies show favorable evidence for using MT in posterior circulation ischemic strokes, demonstrating high recanalization rates, better 90-day functional outcomes, and reduced mortality compared to BMT. The safety profile is acceptable, with slightly higher rates of symptomatic intracranial hemorrhage but reduced mortality.

Efficacy and safety of melatonin for migraine prevention in children and adolescents: a systematic review and meta-analysis

Isabella Christina Amaral de Lara[1], Mariana Rachas Reis[2], Matheus Ricardo Malveira Camacho[3], Amanda Gabriela Freitas Rodrigues[4], Ademar César Ignácio de Moraes[5]

[1]Universidade Cesumar, Maringá PR, Brazil.
[2]Santa Casa de Misericórdia de São Paulo, Faculdade de Ciências Médicas, São Paulo SP, Brazil.
[3]Universidade do Estado do Pará, Belém PA, Brazil.
[4]Universidade Federal do Pará, Belém PA, Brazil.
[5]Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Isabella Christina Amaral de Lara; Email: isabellaadelara@gmail.com.

Background: Migraine is known to be the most prevalent primary headache in pediatric and adolescent patients, affecting around 28% of teenagers. Besides this, only a limited number of prophylactic treatments have proven effective for these age groups. Melatonin, a hormone primarily produced by the pineal gland, plays an important role in the modulation of the circadian rhythm and has shown effectiveness in preventing migraines in adults in previous studies. However, its efficacy in younger patients remains uncertain. **Objective:** To assess the safety and efficacy of melatonin for migraine prophylaxis among children and adolescents. **Methods:** Pubmed, Scopus, Web of Science, and Cochrane databases were systematically searched for randomized controlled trials (RCTs) testing melatonin for migraine prevention in pediatric or adolescent populations. A random-effects model was used to calculate the

mean differences (MDs) with 95% confidence intervals (CIs). Heterogeneity was determined using I^2 statistics. Efficacy was assessed based on headache frequency, while safety was evaluated by adverse events (AEs), including daily sleepiness, nausea, vomiting, worsened headache, worsened movement sensitivity, elevated heart rate, flu-like symptoms, constipation, fatigue, malaise, and fever. Statistical analysis was conducted using R, version 4.4.0. **Results:** We included 4 RCTs with 238 patients. The mean age ranged from 9.28 to 15.00 years, with a majority of female patients (55.9%). Compared with the control group, melatonin use was associated with a significant reduction in monthly headache days (MD 2.93 days; 95% CI 0.72-5.14; p=0.009310; I^2=65%). Additionally, the meta-analysis showed that the incidence of adverse events in the intervention group was comparable with control, hence, not associated with melatonin use (17.3% vs 24.24%; MD 0.69; 95% CI 0.22-2.12; p=0.518081; I^2=37%). **Conclusion:** This systematic review and meta-analysis suggest that the use of melatonin in younger patients with migraine leads to a reduction in monthly headache frequency. While AEs were reported, their incidence was comparable to the control group, indicating a favorable safety profile.

Efficacy and safety of mycophenolate in AQP4-AB negative neuromyelitis optica spectrum syndrome associated with encephalopathy: report of a case

Marcella Turon Baran[1], Thais Lavinas Moura Baptista Barroso[1], Marina Papais Alvarenga[2], Marcos Papais Alvarenga[2], Regina Maria Papais Alvarenga[2]

[1]Universidade de Vassouras, Vassouras RJ, Brazil.
[2]Hospital Federal da Lagoa, Rio de Janeiro RJ, Brazil.

Correspondence: Regina Maria Papais Alvarenga; Email: reginaunirio2016@gmail.com.

Case presentation: A 30-year-old white woman presented with a headache and left unilateral amaurosis and a normal cranial MRI (February 2007). One month later, she developed transverse myelitis syndrome with an extensive longitudinal spinal cord lesion identified on cervical MRI. Treated with methylprednisolone (1g/day /5days) led to gait improvement but not visual recovery. In August 2007, she developed right hemiplegia and aphasia. Brain MRI revealed an extensive left hemispheric lesion. Hospitalized, she received methylprednisolone and intravenous human immunoglobulin (cycles/IV) with partial symptom improvement. Three months later, still hospitalized, she experienced bilateral vision loss, worsening motor dysfunction, and new left cerebral lesion expansion with additional right occipital lesion. She underwent plasmapheresis followed by monthly pulse therapy with methylprednisolone and human immunoglobulin, leading to partial recovery of visual and cognitive manifestations. In 2008, she started off-label preventive treatment with mycophenolate (1g/day). Serial MRIs showed no new brain or spinal lesions. Testing for NMO-IgG antibodies in 2009 by indirect immunofluorescence and in 2017 by Cell Based Assay (CBA), considered the gold standard, were normal. At the last visit, she walked with support, had moderate motor dysfunction in her lower limbs and severe in the right upper limb, communicated verbally, and maintained left amaurosis. Mycophenolate treatment demonstrated complete efficacy and safety over a 10-year follow-up period. **Discussion:** Diagnostic criteria for Neuromyelitis Optica Spectrum Disorders (NMOSD) have evolved, with recognition of neurological syndromes beyond optic nerve and spinal cord involvement since 2006. This new criterion identified 6% of cases with extensive brain lesions in the NMO Mayo Clinic series. In 2015, NMOSD classification included AQP4-AB serological status. This patient, negative for AQP4-IgG by CBA, meets NMOSD AQP4-negative criteria and, despite experiencing four acute and severe events in the first year of disease, including encephalopathy with extensive brain lesions, achieved complete efficacy with off-label oral mycophenolate, endorsed in 2021 by a Latin American consensus of specialists as a first-line drug for NMO treatment. **Final comments:** Cases of NMO with extensive brain lesions are rare; we identified only six among 128 patients in our cohort. Highlighting that FDA-approved therapies are indicated only for AQP4-IgG-positive patients, we emphasize the indication of mycophenolate, which was a safe and effective treatment over ten years of follow-up.

Efficacy and safety of rituximab in a Brazilian cohort of patients with refractory myasthenia gravis

Amanda Vitória Freire de Oliveira[1], Ana Flávia Andrade Lemos[1], Lucas Gondim Briand Vieira[1], Mariana Ribeiro Pereira[1], Mateus Gustavo Favaro[1], Rodrigo Siqueira Soares Frezatti[1], André Cleriston José dos Santos[1], Claudia Ferreira da Rosa Sobreira[1], Wilson Marques Junior[1], Pedro José Tomaselli[1]

[1]Universidade de São Paulo, Ribeirão Preto SP, Brazil.

Correspondence: Amanda Vitória Freire de Oliveira; Email: amandinha_ba@yahoo.com.br.

Background: Myasthenia gravis is an autoimmune disease characterized by muscle weakness and fatigability. The pathophysiological mechanism is mediated by B cells, with auto antibodies directed against proteins specific located in the postsynaptic membrane of the neuromuscular junction. **Objective:** To analyse the safety and efficacy of anti CD20 monoclonal antibody (Rituximab) in the treatment of patients with diagnosis of Myasthenia Gravis who are refractory to first-line medications, followed up at the referral centre of neuromuscular disorders at the Clinical Hospital of Ribeirão Preto, University of São Paulo. **Methods:** Patients with a definitive diagnosis of Myasthenia Gravis, defined by the presence of typical clinical features, along with at least one of the following criteria: repetitive nerve stimulation electromyography showing a decrement in Compound Muscle Action Potential, amplitude between the first and fourth responses greater than 10% in at least two muscle groups; presence of anti-AChR or anti-MuSK antibodies; or single-fiber EMG demonstrating altered jitter or the presence of blocking. Patients with a defined failure or absolute contraindication to the use of first-line medications, who received Rituximab as a rescue therapy and were followed up were recruited. The number of exacerbations, MGFA scale, and MG-ADL scale were observed before and after Rituximab administration. The MGFA and MG-ADL scales were assessed 4 weeks after induction. **Results:** A total of thirty-three patients were recruited. Of these, 5 patients were excluded due to overlap syndromes with other diseases that could confound the clinical picture. Among the recruited patients, 82.14% were women. The age distribution at onset was as follows: 57.14% had early-onset (19-50 years), 25% had late-onset (>50 years), 10.7% had juvenile-onset (≤18 years), and 7.16% had very late-onset (>65 years). Almost all patients (96.4%) exhibited generalized Myasthenia Gravis at the time of evaluation, with only 3.6% presenting ocular MG. Regarding serological status, 82.13% of the patients were seropositive: 60.71% had anti-AChR antibodies and 21.42% had anti-MuSK antibodies. Out of the 28 evaluated patients, 60.71% experienced a reduction in clinical exacerbation following Rituximab administration. Additionally, 71.4% and 42.8% showed improvement in the MG-ADL and MGFA scales, respectively. Twenty-five patients were on corticosteroid therapy prior to Rituximab treatment. Post-Rituximab, 80% of these patients were able to reduce their corticosteroid dose, of which 36% discontinued corticosteroid use entirely. All 28 patients were also using Pyridostigmine; following Rituximab administration, 35.71% of them reduced their Pyridostigmine dose. **Conclusion:** These findings suggest that Rituximab is effective in reducing clinical exacerbations and improving functional outcomes in patients with Myasthenia Gravis, as evidenced by the significant improvements in MG-ADL and MGFA scores.

https://doi.org/10.5327/CBN240635

Efficacy and safety of tacrolimus for myasthenia gravis: a systematic review and meta-analysis

Lorhayne Kerley Capuchinho Scalioni Galvao[1], Nicole dos Santos Pimenta[2], Ana Clara Felix de Farias Santos[3], Deivyd Vieira Silva Cavalcante[4], Fernanda Valeriano Zamora[5], João Pedro Costa Esteves Almuinha Salles[6], Rodrigo Tomazini Martins[7]

Correspondence: Ana Clara Felix de Farias Santos; Email: anafelix625@gmail.com.

Background: Myasthenia gravis (MG) is an autoimmune neuromuscular disorder characterised by muscle weakness and fatigability due to autoantibodies targeting the neuromuscular junction. While conventional treatments like acetylcholinesterase inhibitors and corticosteroids are effective for many, some patients face refractory disease or intolerable side effects, necessitating alternative therapies. Tacrolimus, a potent calcineurin inhibitor used in organ transplantation, has emerged as a promising option for such challenging cases. Tacrolimus modulates the immune response underlying MG by suppressing T-lymphocyte activation and antibody production against acetylcholine receptors, suggesting potential efficacy in symptom management and reducing reliance on other immunosuppressants. **Objective:** This systematic review and meta-analysis assesses current evidence on tacrolimus for MG, exploring its therapeutic benefits, safety profile, and the need for further research on optimal dosing and long-term management. **Methods:** A comprehensive search of PubMed, Embase, and Cochrane databases up to June was conducted to identify studies comparing tacrolimus with placebo or standard treatments in MG patients. We calculated odds ratios (ORs) for categorical outcomes and mean differences (MDs) for continuous measures, with 95% confidence intervals (CIs). A random-effects model was used with statistical significance set at p<0.05. Data were analysed using R software (version 4.4.0), and heterogeneity was assessed using I^2 statistics. **Results:** Eight studies involving 1083 patients were included, with 595 (54.94%) receiving tacrolimus. Tacrolimus treatment showed significant improvements in MG Activities of Daily Living (MG-ADL) scores (MD -0.91 points; 95% CI -1.50, -0.33; p<0.01; I^2=0%) and the proportion of patients achieving minimal myasthenic symptoms or better (OR 0.70; 95% CI 0.52, 0.92; p=0.011; I^2=0%). There were no significant differences between groups in prednisolone dose at endpoint (MD -3.70 mg; 95% CI -8.80, 1.40; p=0.15; I^2=92%), incidence of adverse events (OR 0.73; 95% CI 0.31, 1.69; p=0.462; I^2=60%), or Quantitative MG score (QMG score) (MD 0.20 points; 95% CI -2.31, 2.70; p=0.88; I^2=88%). **Conclusion:** Tacrolimus demonstrated significant efficacy in improving MG-ADL scores and achieving minimal myasthenic symptoms or better, with no significant differences in prednisolone dose compared to standard care. The incidence of side

effects was also similar between the groups. These findings support tacrolimus as a viable treatment option for MG, highlighting its potential to enhance patient outcomes in clinical practice.

Efficacy and safety of tirofiban in acute ischemic stroke patients not receiving endovascular treatment: a systematic review and updated meta-analysis

João Marcelo Lorga Carnielli[1], Danilo Augusto Fernandes Moura[1], Guilherme Augusto Guimarães Resende[1], Pedro Henrique Gorri Custódio de Melo Brites[1], Maria Clara de Mattos Mira[1], Julia Favaro Brenny[2], Fernanda Peres Tomazoli[1], Camilla Stringuetta Galo[3], João Felipe Hermann Costa Scheidt[3]

[1]Universidade Estadual de Maringá, Maringá PR, Brazil.
[2]Universidade Estadual de Londrina, Londrina PR, Brazil.
[3]Hospital Evangélico de Londrina, Londrina PR, Brazil.

Correspondence: João Marcelo Lorga Carnielli; Email: joao_lorga@hotmail.com.

Background: Stroke is a leading cause of death and disability worldwide. Antiplatelet drugs are known to be effective in the treatment and prevention of acute ischemic stroke. However, the role of tirofiban, a nonpeptide selective inhibitor of the platelet glycoprotein IIb/IIIa receptor, in the treatment of acute ischemic stroke in patients not receiving endovascular treatment, remains under discussion. **Objective:** To determine the efficacy and safety of tirofiban, either as monotherapy or in combination with other standard therapies, in treating acute ischemic stroke in patients not undergoing endovascular treatment. Material and **Methods:** PubMed, Embase and Cochrane Library databases were searched for randomized controlled trials and observational studies on tirofiban therapy for acute stroke published up to April 22, 2024. Reviews, case reports, preclinical studies or single-arm studies were excluded. Studies in which patients underwent mechanical thrombectomy were also excluded. Meta-analysis were conducted using a random-effects model. The data were pooled as odds ratios (OR) with 95% confidence intervals (CI). A p-value<0.05 was considered statistically significant. Significant heterogeneity was defined as I2>50%. The safety outcomes included symptomatic intracranial hemorrhage (sICH), any intracranial hemorrhage (ICH), and mortality. The efficacy outcome was the modified Rankin Scale (mRS) score at the 3-month follow-up. **Results:** twenty-four studies, including 13 randomized clinical trials, were included in this systematic review. The meta-analysis indicates that treating ischemic stroke with tirofiban does not increase the incidence of any intracranial hemorrhage (OR 1.00, 95% CI 0.74-1.36, p=0.98, I2=0%), as well as symptomatic intracranial hemorrhage (OR 0.92, 95% CI 0.45-1.89, p=0.82, I2=0%) and mortality (OR 0.71, 95% CI 0.401.26, p=0.25, I2=47%). Additionally, the rates of mRS score of 0-2 (OR 1.89, 95% CI 1.49-2.40, p<0.00001, I2=46%) after 90 days significantly improved in the tirofiban group. The rates of mRS score of 0-1 (OR 1.87, 95% CI 1.33-2.64, p=0.0003, I2=65%) after 90 days were significantly higher in the tirofiban group; however, significant heterogeneity was observed in this specific analysis as well. **Conclusion:** treatment of acute ischemic stroke with tirofiban has shown to be safe compared to standard treatment alone, with a low incidence of adverse effects such as intracranial bleeding and mortality. Overall analysis has demonstrated a significant improvement in mRS score in the tirofiban group, indicating a better prognosis. Subgroup analysis could be conducted to decrease the levels of heterogeneity in the analysis of the rates of mRS score of 0-1. In conclusion, tirofiban is effective and safe in treating acute ischemic stroke when compared with standard treatment alone.

Efficacy and safety of vamorolone in improvement of muscle function in Duchene muscle dystrophy: a systematic review and meta-analysis

Francisco Jazon de Araújo Neto[1], Jamine Yslailla Vasconcelos Rodrigues[1], Thomas Silva de Queiroz[1], Honohrária Bolivya Alencar de Oliveira[1], Gabriel de Almeida Monteiro[1], Espartaco Moraes Lima Ribeiro[1], Marcondes Pimentel Cruz[1], Paulo Roberto Lacerda Leal[1]

[1]Universidade Federal do Ceará, Sobral CE, Brazil.

Correspondence: Jamine Yslailla Vasconcelos Rodrigues; Email: jamineysl@gmail.com.

Background: Duchenne muscular dystrophy (DMD) is a rare and a progressive neuromuscular disorder caused by variants in the DMD gene. Treatment of corticosteroids slows the progression of weakness, but chronic glucocorticosteroid (GC) treatment causes significant morbidities. Vamorolone is a first-in-class, dissociative, synthetic steroidal anti-inflammatory drug that has been studied as an alternative for DMD treatment. A recent randomized controlled trial (RCT) provided new evidences regarding the effectiveness of vamorolone in DMD. Thus, we decided to perform an updated meta-analysis to assemble the current knowledge and reduce uncertainties regarding the use of the vamorolone in DMD treatment. **Objective:** To investigate whether vamorolone is an effective treatment for DMD. **Methods:** We systematically searched PubMed, Embase, and Cochrane Library, for randomized controlled trials (RCTs) and cohort studies comparing vamorolone versus placebo or glucocorticoids for Duchenne muscular dystrophy treatment. The outcomes of interest were Time To Stand From Supine (TTSTAND) and Time To Run/Walk 10 meters (TTRW). We pooled analysis of mean difference (MD) with 95% confidence intervals (CI) applying a random-effects model and using Review Manager 5.4.1 for all statistical analyses. **Results:** We included 2 RCTs and 3 non-randomized clinical trials comprising 391 patients, 181 in the vamorolone groups, 136 in the GC group, and 74 in the placebo group. The pooled analysis showed a statistically significant association between the vamorolone larger doses (≥2 mg/kg/d) group and an increase in the TTSTAND, compared to the placebo group (MD 0.11; 95% CI 0.10, 0.12; P<0.001), but non-significant results when compared to the GC group (MD -0.01; 95% CI -0.02, 0.00; P<0.001). Vamorolone in 2mg dosage also had a greater TTRW compared to the placebo group (MD 0.20; 95% CI 0.15, 0.25; P<0.001) and GC group (MD 0.14; 95% CI 0.11, 0.16; P<0.001). In addition, when comparing the vamorolone groups (vamorolone 2mg versus vamorolone 6mg), the vamorolone 2mg group had a significantly better results in the TTSTAND (MD -0.02; 95% CI -0.03, -0.02; P<0.001), but the vamorolone 6mg group had better results in the TTRW (MD 0.11; 95% CI=0.09, 0.14; P<0.001). **Conclusion:** Vamorolone improved TTSTAND in comparison with the placebo and the TTRW compared with placebo and glucocorticoids. Vamorolone 2mg group showed better results in TTSTAND compared to the 6mg group, while the 6mg group showed better results in TTRW. Larger, higher-quality randomized studies are needed to adequately evaluate the efficacy, safety and optimal dose of vamorolone in DMD.

https://doi.org/10.5327/CBN240638

Efficacy of botulinum toxin in the management of trigeminal neuralgia: a systematic literature review

Geovanna Barros Rocha[1], Naely Nobre Costa[1], Stefanne de Cássia Pereira da Silva[1], Laura Lino Gonçalves[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Geovanna Barros Rocha; Email: geovannaroccha@outlook.com.

Background: Trigeminal neuralgia is characterized by unilateral, brief, shock-like paroxysmal pain, evoked by touch, which affects patients' daily activities, causing a direct impact on general status, sleep, mood and psychological health. The incidence of trigeminal neuralgia varies between 4.3 and 27 new cases per 100,000 people per year, being more common in women and increasing with age. The condition can lead to significant disability, with up to 45% of patients absent from their usual activities for 15 days or more. The initial treatment is pharmacological, with anticonvulsants, although many patients experience refractory pain. In this context, botulinum toxin type A has shown benefits in the treatment of neuropathic pain, reducing pro-inflammatory mediators and may be a safe and effective alternative in the management of trigeminal neuralgia refractory to conventional treatment. **Objective:** To analyze the variables associated with the treatment of trigeminal neuralgia using botulinum toxin. **Methods:** A systematic review was carried out, based on the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, using the PECO strategy, to search the PubMed and Virtual Health Library (VHL) databases, including studies from 2014 to 2024, in English, Portuguese and Spanish. **Results:** 395 articles were found, of which 4 randomized clinical trials met the stipulated inclusion criteria, with only 3 being included in the study, due to the high risk of bias presented in one of them. Regarding participants, the average was 45 participants aged 57 years, the majority of whom were male. They were divided into a test group (GT) and control group (CG), which received, respectively, doses of botulinum toxin (25U to 100U) and placebo (doses of intramuscular saline solution). In the GT, a reduction of 66% was found at the 25U dose, 46% at the 50U dose and 78% at the 100U dose. In the CG, an average reduction of 20% was obtained. The main adverse effects found were: facial asymmetry and hematoma, ecchymosis and pain at the injection site. **Conclusion:** The use of botulinum toxin in trigeminal neuralgia was effective and safe in the articles analyzed, with mild and transient adverse effects and significant results in reducing pain compared to the placebo group, however, it was not possible to directly correlate doses higher doses of botulinum toxin with greater reductions in the pain scale. Therefore, it is important to carry out more clinical studies in this field, in order to elucidate the standardization of doses and the ideal stipulated therapy time.

Background: Numerous observational studies have investigated the use of lanreotide for pituitary tumors. However, it remains unclear whether there is a difference between injectable sustained-release (SR) or autogel formulations for tumor reduction. **Objective:** Therefore, we conducted a systematic review and meta-analysis to assess the efficacy of these drugs in mean tumor reduction. Additionally, we evaluated the proportion of patients experiencing any tumor shrinkage with different lanreotide formulations. **Methods:** We searched PubMed, Embase, and Cochrane Central for studies assessing injectable SR or autogel lanreotide for treating pituitary adenomas. We computed pooled mean difference (MD) or Risk Ratios (RR) for continuous and binary outcomes, respectively, with 95% confidence intervals (CI). A random effects model was used for the analysis. Heterogeneity was assessed with I2 statistics. Statistical analyses were performed with the R program (version 4.3.2) **Results:** We included eighteen studies comprising 892 patients, of whom 150 (41.7%) were treated with lanreotide autogel and 210 (58.3%) with injectable SR lanreotide. The mean age was 48.5 (12.3) SD, and 52.35% were female. Mean tumor reduction in patients using any formulation of lanreotide was 42% (95% CI=0.29 to 0.54; I2=94%). Overall, the proportion of patients experiencing any tumor reduction was 42% (95% CI=0.271 to 0.585; I2=88%). Such a proportion was 41% (95% CI=0.30 to 0.52; I2=82%) in those treated with injectable SR lanreotide, and 34% (95% CI=0.22 to 0.47; I2=82%) in those receiving autogel lanreotide. **Conclusion:** Lanreotide was associated with significant pituitary adenoma shrinkage. Moreover, subgroup analyses showed a higher proportion of patients with any tumor reduction in the injectable SR lanreotide group relative to the autogel lanreotide group.

Correspondence: Gabrielle Gomes Garcia; Email: gabriellegarcia3g@gmail.com.

Background: Alzheimer's disease (AD) is the most prevalent type of dementia, characterized as a progressive neurodegenerative disease. About 25 to 50% of patients present with psychosis, featuring hallucinations and delusions. To this date, there are few safe and effective treatments available to treat this condition. New studies aim to explore the use of pimavanserin, an atypical antipsychotic that acts on the central nervous system, blocking the effects of the serotonin 5-HT2A receptor. It is being tested in individuals with psychosis in AD and has been approved by the FDA for the treatment of psychosis in Parkinson's disease. **Objective:** To evaluate the efficacy of pimavanserin for patients with psychosis in Alzheimer's disease. **Methods:** This literature review adhered to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. Studies searched four electronic databases: Cochrane, Pubmed, Lilacs and SciELO. The keywords used were: (alzheimer disease OR alzheimer dementia) AND (pimavanserin) AND (psychotic disorders). Randomized clinical trials published from 2014 to 2024, in English, and targeting the adult population were included. The exclusion criteria are as follows: trials not involving humans; no full text; non-randomized controlled studies. **Results:** 23 publications were found in the databases, and 9 of these were duplicates. Of the remaining 14, 6 studies were excluded as they did not fulfill the inclusion criteria. In the final analysis, only 3 original clinical trials were considered, with the remaining 5 publications referring to these same studies. In only one trial, all the individuals had AD (n=181), showing a 39.5% reduction in the psychosis score (NPI-NH) after 6 weeks of treatment with pimavanserin, 34 mg daily, compared to 19.3% in the placebo group. In the other trials, dementia and psychosis patients were analyzed, most of them suffering from AD (520 out of 1176). In these analyses, pimavanserin-responsive patients had fewer relapses (13%) of psychosis with the continuation of the drug than the placebo group, which discontinued treatment after 12 weeks (28%). Additionally, pimavanserin showed an improvement in the CGI-I neuropsychiatric scale compared to the placebo group, at the end of 8 weeks of treatment (mixed-effects model repeated measures analysis showed a least square means difference of -0.2 with a standard error of 0.07 (p=0.0140)). **Conclusion:** Primavanserin demonstrated positive results in treating psychosis in patients with AD. Also, the effects obtained indicate a potential efficacy in preventing psychotic relapses. However, the limited number of studies conducted so far investigating this therapeutic possibility, in addition to the limitations observed in the existing clinical trials, make this evidence questionable. Further studies are necessary in order to prove its benefits in these patients.

[3]Universidade do Oeste Paulista, Presidente Prudente SP, Brazil.

Correspondence: Pedro Henrique Ximenes Ramalho Barros; Email: pedrohx587@gmail.com.

Background: Although the efficacy of apomorphine in the treatment of Parkinson's disease (PD) is subject to debate, it emerges as a promising option, especially for advanced cases. Not yet widely adopted in Brazil, its use stands out in recent studies, suggesting that this substance may offer significant benefits, challenging conventional perceptions and sparking interest in advanced disease management. **Objective:** To evaluate the efficacy of subcutaneous apomorphine in reducing motor symptoms in PD patients. **Methods:** Researchers systematically searched for randomized clinical trials comparing apomorphine and placebo in PD patients. The primary outcome of interest was the change in the UPDRS III scale up to 20 minutes after the intervention and after 90 minutes. Statistical analysis was performed using R Studio 4.3.2 software. **Results:** Three studies were included, totaling 163 patients. The average dose administered ranged from 4 to 5.4mg. The mean difference in the UPDRS III scale between the apomorphine and placebo groups was -14.12 points (95% CI -23.87 to -4.37; p<0.01; I^2=92%) up to 20 minutes after the intervention and -3.27 points (95% CI -6.12 to -0.43; p=0.02; I^2=0%) after 90 minutes. Meta-regression results applied to the outcome up to 20 minutes showed that the dosage accounted for 53.46% of the heterogeneity among studies and for 88.64% of the mean difference. The test for residual heterogeneity was not significant (p=0.171). The intercept of the regression plot was 38.01 points and the coefficient corresponding to the dosage was -11.24 points (p=0.0017). **Conclusion:** Evaluating the efficacy of subcutaneous apomorphine in PD, there was statistical significance for the reduction of motor symptoms of the disease.

Eight-and-a-half syndrome due to pontine stroke: a case report

Laura Alonso Matheus Montouro[1], Luísa Bigatão Inácio[1], Júlia Gon Perez Nardoque[1], Giulia Rago Constâncio[1], João Renato Villas Bôas[1], Marina Morandin Rinaldi[1], Lívia Buqui Mazzoni[1], Rafaela de Freitas Valverde[1]

[1]Centro Universitário Padre Albino, Faculdade de Medicina de Catanduva, Catanduva SP, Brazil

Correspondence: Luísa Bigatão Inácio; Email: luisab.inacio@hotmail.com.

Case presentation: Female, 54 years-old, admitted in emergency with diplopia, eye movement abnormalities, vomiting and dizziness. On neurological examination, the patient scored 15 points on the Glasgow Coma Scale and 6 points on the National Institutes of Health Stroke Scale (NIHSS). The evaluation of cranial nerves: poor light reflex of left pupil, conjugate gaze deviation, divergente strabismus and nystagmus in the left eye and rhyme deviation to the left. About the muscle strength, the patient had a grade IV motor déficit according to the Medical Research Council in the left hemibody and no motor deficit in the right hemibody. The sensitivity analysis did not exhibit any changes. Brain magnetic resonance imaging (MRI) reveals lesions at dorsal pons and at small are of splenium of the corpus callosum and left occipital lobe characterized by high signal intensity on T2-weighted and Fluid-Attenuated Inversion Recovery (FLAIR) sequences, with real restricted diffusion on DWI/ADC map. **Discussion:** First reported by Eggenberger et al. in 1998, eight-and-a-half syndrome (EHS) is caused by a lesion of the abducens nucleus, pontine portion of the facial nerve and the medial longitudinal fasciculus (dorsal pons). Consequently, there'll be facial nerve palsy, horizontal gaze palsy and internuclear ophthalmoplegia (one-and-a-half syndrome plus VII nerve palsy). Rare neuro-ophthalmologic manifestation, 35 cases reported and two of them from brazilian origin. Cerebrovascular disease and demyelinating disease represents 90% of case etiologies. **Final comments:** Here, we report the third case of EHS in Brazil, caused by a pontine stroke. It is essential to know the complex anatomy of the pons and its pathways for the diagnosis of EHS and for the reasoning of the etiological investigation.

Electroencephalography findings in a girl with Zellweger syndrome: case report

Bruno Eiji Nakano[1], Déborah Castro Ferreira de Oliveira[1], Paulo Emídio Lobão Cunha[1], Pedro Sudbrack Oliveira[1], Pedro Vicente Ferreira Naves[1], Isadora de Oliveira Cavalcante[1], Priscila Martins Câmara[1], Jennifer Jorge de Sales[1], Flavia Nunes da Silva Ferreira[1], Thaline Tiemi Nakano[2]

[1]Universidade de Brasília, Hospital Universitário de Brasília, Brasília DF, Brazil.
[2]Universidade Anhembi Morumbi, São Paulo SP, Brazil.

Correspondence: Bruno Eiji Nakano; Email:

Case presentation: A 2.5 year old girl, born full term, cesarean section with craniofacial dysmorphisms (large posterior fontanelle at birth), findings under neonatal hearing screening and abnormal liver enzyme tests. She also developed neonatal jaundice which required phototherapy. At 6 months of age, a magnetic resonance imaging of the brain and electroencephalogram (EEG) were carried out without any alterations. Generalized hypotonia, delayed neuropsychomotor development, severe cortical visual impairment, hearing impairment, hepatic dysfunction and severe oropharyngeal dysphagia

were identified. Exome sequencing identified two probably pathogenic variants, both in heterozygosity and in trans, in exon 1 and 8 of the PEX6 gene, associated with Peroxisome Biogenesis Disorder 4A (Zellweger) of autosomal recessive inheritance. She has 3 siblings with sickle cell trait and autism spectrum disorder, healthy parents and no history of consanguinity. At the age of 2.5, episodes of apnea lasting a few seconds onset. The EEG showed moderately disorganized background activity, occasional interictal epileptiform discharges (IEDs) of varying morphology (spike, sharp wave and polyspike-wave complexes) with multifocal distribution, predominating on the right side. **Discussion:** Zellweger syndrome is part of a group of genetic diseases related to the biogenesis of peroxisomes that, together with neonatal adrenoleukodystrophy and infantile Resfum's disease, constitute Zellweger spectrum disorders (ZSD). ZSD are autosomal recessive disorders with an incidence of 1:50,000 births and are related to mutations in the PEX gene, responsible for encoding the peroxin protein. The pathophysiology is related to a reduction in the number and dysfunction of peroxisomes. The clinical manifestations are varied, but include decreased muscle tone, facial dysmorphisms, growth delay, sensory and neurological dysfunction, renal and endocrine insufficiency, skeletal anormalies and developmental delays. Developmental brain malformations can be seen on MRI while electroencephalography may include diffuse cerebral dysfunction, continuous negative sharp waves and spikes at the vertex, and bilateral independent multifocal spikes, predominantly in the frontal motor cortex and its surrounding regions. Treatment consists of symptomatic therapy, multidisciplinary monitoring and genetic counseling. **Final comments:** The case is extremely relevant as it portrays a patient with no history of seizures, who started with apnea and whose EEG identified multifocal IEDs. These findings further reinforce the great clinical variability and complementary tests that can have a direct impact on the best management of the disease.

Correspondence: Bruno Eiji Nakano; Email: bruno.nakano1@gmail.com.

Case presentation: A 6-year-old male with expected neuropsychomotor development up to 2.5 years of age began to show language regression (echolalia and phonetic changes) with an impact on socializing. At the age of 3, the M-CHAT score was applied with a result of 8 and Autism Spectrum Disorder was considered. At the age of 5, verbal communication worsened. The cranial computed tomography scan showed no alterations and the electroencephalogram (EEG) showed occasional bilateral interictal epileptiform discharges (IEDs) in the centroparietal region, predominantly on the left. Valproic acid and periciazine were prescribed for behavioral control, with improvement but speech alterations remaining. The diagnostic hypothesis of Landau-Kleffner syndrome was considered and prednisolone (1.3mg/kg) was prescribed for 28 days. The patient's speech improved after taking the corticosteroid. **Discussion:** Laudau-Kleffner syndrome is a rare condition, with a common onset between 3-8 years of age and a predominance of 2 to 1 in males, characterized by language loss, IEDs on the electroencephalogram and seizures, although it is present in 80% of cases. Due to the outstanding behavioral alterations, the syndrome tends to have autism spectrum disorder and other cognitive disorders (neurodegenerative, traumatic, vascular) as a differential diagnosis and is therefore often diagnosed later, especially in cases where language dysfunction begins in younger children with a lower vocabulary. EEG findings show great variability, such as IEDs with polyspike, spike-wave, usually multifocal and bilateral, sometimes with a predominance in the temporal and parietal regions, activated mainly during non-rapid eye movement (NREM) sleep. In addition to these findings, it has been reported that a vertically oriented dipole can be found in the intraperisylvian region. **Final comments:** This case is extremely relevant, as it reinforces the variability in the morphology of IEDs which, associated with the wide range of clinical manifestations that make early diagnosis of Landau-Kleffner syndrome even harder, with a greater chance of cognitive sequelae.

Elevated plasma levels of miR-206 in adult spinal muscular atrophy patients: a potential biomarker

Alexandre Hilário Berenguer de Matos[1], Felipe Franco da Graça[1], Cristina Iwabe[1], Marcondes Cavalcante França-Jr[1]

[1]Universidade Estadual de Campinas, Departamento de Neurologia, Campinas SP, Brazil.

Correspondence: Alexandre Hilário Berenguer de Matos; Email: alexandrehbm@gmail.com.

Background: Biomarkers are needed to assist in the management and follow-up of patients with spinal muscular atrophy (SMA) and circulating microRNAs (miRNAs) emerge as potential candidates. MiRNA-206 is involved in the denervation-reinnervation process and found to be clinically useful in amyotrophic lateral sclerosis. **Objective:** To analyze miRNA-206 expression in the plasma of adult patients with SMA and compare these results with healthy controls. **Methods:** Blood samples were collected from 28 adult patients with genetically confirmed spinal muscular atrophy (SMA) and 11 healthy controls. Blood was centrifuged, plasma was separated, and stored at -80°C. An RNA-enriched fraction was extracted from 200µl of plasma using the miRNeasy Serum/Plasma Advanced Kit (Qiagen®). Following this, the miRNA TaqMan® Advanced Kit was used for cDNA synthesis and specific assays to determine miR-206 expression levels in serum via RT-qPCR (Thermo®). Paired T-tests and Mann-Whitney U tests were used to assess significant differences in the expression of the selected gene. The significance level was set at $p \leq 0.05$. **Results:** The quantification revealed a significant ($p \leq 0.05$) increase in the relative expression of miR-206 in the plasma of SMA patients compared to healthy controls. This finding suggests a potential association between elevated miR-206 levels and the pathophysiology of SMA, further investigation is needed to elucidate the functional and clinical implications of this phenomenon. Interestingly, our results are consistent with previous findings demonstrating elevated miR-206 levels in adult patients with ALS, another motor neuron disease. **Conclusion:** Overall, our data suggest the potential of miR-206 as a stable and reproducible plasma biomarker for patients with spinal muscular atrophy (SMA). Further studies are necessary to investigate the correlation between miR-206 levels and clinical severity, as well as disease progression in SMA patients.

Background: Recent evidence suggests a beneficial effect of endovascular thrombectomy (EVT) in acute ischaemic stroke (AIS) with large infarct in comparison with standard medical treatment (SMT) alone. A previous meta-analysis evaluated the impact of EVT in AIS with extreme low ASPECTS (≤2). However there is no current comparative meta-analysis in the literature evaluating the effect of EVT in AIS with moderate to low ASPECTS (≤5). **Objective:** To assess the efficacy, the risk of bleeding and the risk of mortality in endovascular thrombectomy compared to standard medical treatment alone in patients with AIS with moderate to low ASPECTS (≤5). **Methods:** Medline, Embase, and Cochrane databases were systematically searched until June 6, 2024, assessing randomized controlled trials (RCTs) comparing EVT and SMT alone in patients with AIS with moderate to low ASPECTS (≤5). The primary outcomes of interest were: (1) proportion of successful reperfusion and (2) modified rankin scale (mRS) 0-2 and (3) 0-3. The secondary outcomes included: death from any cause, intracranial hemorrhage and EQ-5D-5L Utility Index. Data were examined using the Mantel-Haenszel method and 95% CIs for risk ratio (RR) and mean differences (MD). Heterogeneity was assessed using I^2 statistics. Software R Studio was used for statistical analysis. **Results:** Five RCTs were included in the meta-analysis, comprising 1586 patients. A total of 795 patients (50.13%) were assigned to receive EVT. The successful reperfusion was achieved in a proportion of 78.65% (95% CI 73.05% - 84.24%; I^2=61%) among the patients in the EVT group. Regarding mRS 0-2 (RR 2.71; 95% CI 2.04 - 3.61; I^2=0%) and mRS 0-3 (RR 2.04; 95% CI 1.52 - 2.74; I^2=62%), there was statistical significant difference favorable to EVT in neurological disability endpoints. Death from any cause was significantly lower in EVT group (RR 0.82; 95% CI 0.68 - 0.99; I^2=43%) and intracranial hemorrhage was significantly higher in the EVT group (RR 1.65; 95% CI 1.04 - 2.62; I^2=0%). Besides, the EQ-5D-5L Utility Index was significantly higher in the EVT group (MD 0.20; 95% CI 0.12 - 0.28; I^2=0%). **Conclusion:** EVT is an effective option to the treatment of large infarctions with moderate to low ASPECTS (≤5), and improves neurological functional outcomes and reduces mortality in comparison with SMT alone. However, it seems to show a higher risk of intracranial hemorrhage which is an important point to discuss for patients with considerable risk of bleeding.

Background: The qPCR method for microRNA quantification in biological samples has been widely used to analyze clinical samples such as serum and blood plasma, in a quest for informative biomarkers, especially in neurodegenerative diseases. Previous studies suggest that microRNAs could potentially function as biomarkers for RBD, REM-sleep behavioral disease. Successful implementation of the methodology depends on both the microRNA extraction and target amplification protocols producing optimal results. **Objective:** To compare RNA purification and real-time qPCR methodologies for quantifying microRNAs as potential non-invasive biomarkers for RBD. **Methods:** Our cohort consisted of individuals with RBD and healthy controls. Data analysis in this study detected and excluded outliers, with values following a normal distribution. Pairwise group comparisons were carried out using the Student's t-test. RNA purification tests from serum samples of RBD patients and controls were conducted using two commercial kits from Qiagen: the miRNeasy/serum plasma kit and the miRNeasy serum/plasma Advanced kit (Qiagen, Hilden, Germany). Regarding qPCR methodologies, both utilized the Taqman system from Applied Biosystems (Applied Biosystems, Carlsbad, CA, USA). The conventional methodology, without target pre-amplification, was compared with the system based on RNA molecule pre-amplification followed by reverse transcription, known as the Advanced system. **Results:** The miRNeasy serum/plasma Advanced kit showed a significantly higher microRNA yield than the miRNeasy serum/plasma kit, measuring 1.45ng/µL versus 0.61ng/µL (P=0.006). Concerning qPCR methodologies, the Taqman Advanced system outperformed the conventional Taqman system, exhibiting earlier amplifications and more significant CT differences between the experimental groups. The study focused on the microRNA miR-19b-3p, known to have increased expression in RBD. Results revealed significant differences in CT values between the Advanced and conventional systems for both the control and RBD groups. The Advanced system consistently showed earlier amplification and larger CT differences between the groups, particularly for miR-19b-3p. Additional microRNAs, such as miR-7-5p, miR-21-5p, and miR-155-5p, were also examined. MiR-7 showed significant variations in CT values between the RBD and control groups. MiR-21 and miR-155 served as stable endogenous calibrators, along with cel-miR-39-3p as an exogenous spike-in calibrator. **Conclusion:** The current study highlights the importance of utilizing an enhanced RNA extraction system and a qPCR system with pre-amplification for accurate microRNA quantification in RBD. For calibration of the assays, our data recommend the exogenous calibrator spike-in cel-miR-39 and the endogenous miRNAs miR-21 and miR-155.

Epilepsy, a prevalent neurological disorder, often necessitates surgical intervention when pharmacological treatments fail. Accurate postoperative assessment is crucial for evaluating surgical outcomes and guiding future treatment strategies. In this study, we introduce ResectVol DL, a deep learning tool designed to automatically segment and characterize brain lacunas from postoperative MRI scans of epilepsy patients. Developed using the nnU-Net framework and leveraging the 3D U-Net architecture, ResectVol DL offers a fully automatic solution intended to avoid the traditional manual segmentation, which is tedious and time-consuming. Based on the Desikan-Killiany-Tourville segmentation atlas, our tool also identifies brain regions and estimates the volume of the parts removed. The dataset comprised post-operative T1-weighted MRI scans from 120 epilepsy patients who underwent resective surgery, with manual segmentations by experienced raters serving as the ground truth. We used five MRIs from healthy controls to test for false identification of brain lacunas. ResectVol DL demonstrated superior performance compared to two other freely available tools, achieving a median Dice similarity coefficient (DSC) of 0.92 (vs. 0.78 and 0.90), indicating high overlap with manual segmentations. When comparing lacuna volumes obtained manually with those obtained automatically, ResectVol DL presented the highest correlation coefficient (0.99 vs. 0.63 and 0.94) and the lowest median relative difference (9% vs. 44% and 12%). ResectVol showed no false positive results, while one of the other tools found false results in the five control images. The clinical implications of ResectVol DL include a rapid and precise volumetric analysis of resected brain tissue, which facilitates the identification of critical structures affected by surgery, enhancing our understanding of surgical impacts on cognitive and seizure outcomes. Furthermore, the tool's ability to process images without the need for preoperative scans simplifies its integration into clinical workflows. Beyond immediate postoperative evaluation, ResectVol DL holds promise for advancing predictive models estimating seizure freedom and cognitive recovery likelihood by providing volumetric information to feed the training of these models. In line with that, as a freely available tool, it can aid researchers and clinicians worldwide to improve epilepsy patient care through surgical planning and outcome prediction. ResectVol DL's accuracy, efficiency, and clinical relevance can be an asset for neurosurgeons and researchers, with potential to enhance patient care and prognostic capabilities.

Background: Parkinson's disease (PD) is progressive, degenerative, chronic and irreversible, affects the central nervous system, being one of the neurological diseases that most affects individuals in the world, affecting between 1 and 3% of the world population over 60 years of age. **Objective:** To analyze the epidemiological profile of hospitalizations of Parkinson Disease in Brazil between the years 2013 and 2023. **Methods:** This study is an epidemiological investigation of hospitalizations of patients, between 30 and 79 years old, with PD between 2013 and 2023. Data were collected from the Sistema de Informação de Agravos de Notificação (Sinan Net) do Departamento de Informática do Sistema Único de Saúde (DATASUS), and data analysis was performed using Jamovi® software. **Results:** According to the data found in DATASUS, between 2013 and 2023, approximately 8421 hospitalizations of patients with PD in the established age group were recorded in Brazil. The age of hospitalized persons was predominant in the 60-79 age group, accounting for 65.96% of hospitalizations, although the number of persons under 60 years of age was significant (34.03%). There was also an increase in the number of hospitalizations in the years 2014 to 2016 compared to other years, with almost 3000 hospitalizations, and a considerable decrease in 2020, with a reduction of 32.74% compared to the previous year. In addition, making a percentage comparison between hospitalizations in the pre-pandemic period and the pandemic period, a percentage reduction of 24.12% is perceived. In addition, there was a considerable increase in the number of hospitalizations in 2023, with a percentage increase of 13.98% compared to the previous year, as well as an increase of 37.0% in the number of deaths compared to other years.Among these patients, it is also possible to observe a prevalence of males (61.38%), being more prevalent in all age groups, except in patients over 80 years of age. **Conclusion:** According to the data analysis, there is a decline in the number of hospitalizations from 2020 and in the following two years in all regions of the country, which is probably due to the COVID-19 pandemic, whose hospital care was concentrated on covid cases, generating a decrease in the number of hospital admissions for other diseases and in the medical demand by patients themselves. In addition, it is possible to observe an association between the increase in the number of hospitalizations and the number of deaths, especially in the age group of 60 to 79, since in this group it is common to have greater severity of symptoms. Regarding the age group and gender of the patients, there is a greater presence of men in all age groups, except over 80 years of age, which is explained by occupational risk factors, the fact that women have estrogen as a protective fact, and longer life expectancy.

Epidemiologic analysis of the hospitalization of viral encephalitis in Brazil from 2013-2023

Júlia Viana de Castro[1], Matheus Henrique Brustolim Marcucci[1], Paulo Wendel Moura de Souza[1], Cynthia Paz Rodrigues[1], Ana Cecília Neves Rios Parente[1], Amanda Mendes Das Neves[1], Yasmin Dantas Babadopulos[1], Rodrigo Guimarães Bandeira[1], Sofia Santana de Figueirêdo[1], Mário Vinícyus Santos Alves[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Júlia Viana de Castro; Email: juliaviana2020@alu.ufc.br.

Background: Viral encephalitis is inflammation of the brain parenchyma caused by a virus. It is the most common type of encephalitis and often coexists with viral meningitis. Viruses invade the host outside the central nervous system and then reach the spinal cord and brain via hematogenous spread or in a retrograde manner from nerve endings. **Objective:** To analyze the epidemiological profile of confirmed cases of viral encephalitis in Brazil between the years 2013 and 2023. **Methods:** This study is an epidemiological investigation of the prevalence of viral encephalitis cases between 2013 and 2023 in Brazil.

Data were collected from the Sistema de Informação de Agravos de Notificação (Sinan Net) do Departamento de Informática do Sistema Único de Saúde (DATASUS), and data analysis was performed using Jamovi® software. **Results:** During the period of the SARS-CoV-2 pandemic from 2020 to 2022, there was a 24.87% reduction in the number of cases compared to the pre-pandemic period from 2013 to 2019. The reduction from 2019 to 2020, the first year of the pandemic, was 29.28% and from 2020 to 2021, the reduction was 10.08%. However, there was a gradual increase from 2022 onwards, with an increment of 16.56% by 2023. The age group from 40 to 49 years old was the one that suffered the most reduction in the number of cases in the pandemic period compared to the pre-pandemic period, with a percentage difference of 32.08%, and the one that was least affected were individuals from 50 to 59 years old, with a difference of 11.34%. Furthermore, the Northeast region of Brazil had the most considerable difference in the number of cases (16.12%). **Conclusion:** According to the data analysis, there has been a considerable decline in the number of cases during the pandemic period (24.37%) compared to the pre-pandemic period (2013 to 2023). This is due to social isolation, as well as the restrictive and preventive hygiene measures imposed during the pandemic period to control COVID-19, which may have contributed to lowering the rates of viral infections, directly influencing the drop in the number of cases of viral encephalitis. In addition, this difference can also be explained by a reduction in the notification of cases, as well as in hospital demand during the pandemic period, a scenario also seen in other diseases, such as meningitis. This can be verified by the gradual increase in the number of cases from 2022 onwards, whereas in 2023 the prevalence began to approach the values recorded before the pandemic.

https://doi.org/10.5327/CBN240650

Epidemiologic profile of hospitalizations and deaths by brain neoplasms in the state of Bahia between 2013 and 2021

Cauã Araujo de Carvalho[1], Antônio Felipe Rocha Brandão[2], Bruna Rios Beserra[2], Bruno Levy de Souza Amaral Maia[1], Clara Carvalho Dantas Muniz[2], Ellen Santos Barreto[1], Fernanda Almeida da Silva de Sá Oliveira[2], Maria Clara Moysés de Siqueira[2], Thiago Costa Oliveira[2], Cleydson Santos[3]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.
[2]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.
[3]Hospital Mater Dei Salvador e Obras Sociais de Irmã Dulce, Salvador BA, Brazil.

Correspondence: Thiago Costa Oliveira; Email: thiagocoliveira23.1@bahiana.edu.br.

Background: Although rare, primary brain neoplasms consist of an relevant clinical entity with high organic impacts. It is known that the growing incidence of this cancer in Brasil is related to population ageing and to better access to diagnostic services, such as magnetic resonance. Therefore, it becomes necessary to identify its epidemiologic profile to implement health policies that go after the treatment and diagnosis of this illness. **Objective:** Describe the epidemiologic profile of hospitalizations and deaths by primary brain neoplasms in the state of Bahia between 2013 and 2021. **Methods:** Observational, descriptive and quantitative study that highlighted an ecological and retrospective approach of secondary data gathered in DATASUS/TABNET, without needing of approvation by the Ethics Committee. Data comprehend the period between 2013 and 2021 and were gathered in SIH/SUS, Oncology Panel of DATASUS and Mortality Atlas of INCA. There were investigated registers of hospitalizations and deaths by brain neoplasms in Bahia, taking into account the variables sex, age, race/color, therapeutical modality and treatment time. Exclusion criteria were other brazilian states and secondary brain neoplasms. **Results:** Between 2013 and 2021, there were registered 1.485 cases of primary brain neoplasms in Bahia, of which 47.8% (N=709) were in men and 52.2% (N=776) were in women. There was a progressive growth of 153% in notified cases between 2013 (N=97) and 2021 (N=246), mostly in the age range of 30 to 59 years old (51.5%; N=776). There were registered 7,051 hospitalizations at the analyzed period, of which 51.3% (N=3,622) were men and 48.7% (N=3,429) were women. About race/color, 45.5% (N=3,209) of the hospitalized were brown and 47.7% (N=3,364) did not have that information registered. In the analyzed period, radiotherapy was the preferential therapeutic modality, being used in 47.7% (N=704) of treatments, followed by surgery, with 18.2% (N=271), and chemotherapy, with 12.4% (N=185), while 20,4% (N=304) of treatments were not descripted. There were registered 3,800 deaths on the period, with a growth of 20.5% between 2013 (N=375) and 2021 (N=452) and more concentrated on the age range of 50 to 79 years old (N=2,199; 57.9%), mostly men (N=1.958; 51.5%). Mortality raised from 2.49 deaths by 100 thousand habitants (2013) to 3.01 deaths by 100 thousand habitants (2021). **Conclusion:** Brain neoplasms represent a relevant neurological entity which indicators are growing in Bahia. On the analyzed period, men, brown and adults were the most affected population, and radiotherapy was the preferential therapeutic modality, maybe because of inoperable lesions, reflecting late diagnosis and/or difficulty to access reference services. It is recommended the reformulation of health policies and specialized services of diagnosis and treatment of this cancer, in addition to new studies that follow the epidemiologic situation of the illness in Bahia.

[3]Universidade de São Paulo, Ribeirão Preto SP, Brazil.

Correspondence: Thiago Oscar Goulart; Email: tgoulart@hsph.harvard.edu.

Background: Cerebrovascular diseases (CVD) represent a Global Health concern, being the first cause of disability worldwide and second cause of mortality (first in Brazil). Despite that, detailed data from Brazil was scarce and this study found alarming results. **Objective:** The study aims to analyze incidence, mortality, treatment, procedures and costs related to the three most common cerebrovascular diseases: Subarachnoid Hemorrhage (SAH), Intracerebral Hemorrhage (ICH) and Ischemic Stroke in Brazil. **Methods:** This is an epidemiological study. Data was obtained through DataSUS, a public database. For the search, we utilized the CID-10 notification system from I60 until I64, including admissions, deaths, treatments and costs related to each CID-10. **Results:** Between 2017 and 2022, 1,283,435 CVD cases were notified (SAH=4.7%; ICH= 8.8%; and ischemic stroke=86.5%). Admissions follow seasonality and there is evidence of subnotifications in 2020. 52.4% were Male and 47.6% were Female. Mortality percentages were: SAH=20.2%, ICH=25.3%, Ischemic Stroke=15.3%. Rates of Thrombolysis were alarming, but with an increasing tendency: 22969 were performed, from 1.6% in 2017 to 2.3% in 2022 of all ischemic strokes. 8290 aneurysms embolizations were performed (13.5% of all SAH cases). 4.9% of SAH cases were treated with neurosurgical clipping, demonstrating a decrease tendency after 2020, as well other procedures, such as Craniectomy and Angioplastia. Yearly costs related to these diseases increased steeply, from R$ 360,710,749.92 in 2017 to R$ 537,511,793.62 in 2022 (around US$107,502,358.00). **Conclusion:** This study has found increasing incidence and costs associated with low rates of thrombolysis and procedures in Brazil the results can direct Public Health policies in developing countries, and similar research in other low- and middle-income-countries are encouraged.

Epidemiological analysis of deaths due to inflammatory polyneuropathies from 2018 to 2022

Paola Carolina Santos Foinkinos[1], Matheus Prado dos Santos[1], Maria Eduarda da Silva Santos[1], Bruna Martyres Gueiros[1], Zulma Catarina dos Santos Silva[1], Matheus de Carvalho Alves[1], Louise Araújo Corrêa[1], Hellen Jost Evaldt[2], Larissa Ádila Desireé Vieira de Andrade Duarte[1], Suzana Gomes de Oliveira[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.
[2]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Paola Carolina Santos Foinkinos; Email: paola.csfoinkinos@aluno.uepa.br.

Background: Inflammatory polyneuropathies are a group of diseases of the Peripheral Nervous System, which include Guillain-Barré Syndrome (GBS), Chronic Inflammatory Demyelinating Polyneuropathy (CIDP) and others. They are acquired and related to immune response disorders, which affect components of the peripheral nervous system. As a result, these pathologies lead to physical and functional limitations, requiring early diagnosis and correct treatment to improve the clinical condition and prevent deaths. Therefore, a detailed investigation of deaths resulting from these diseases is necessary, as it can serve as a parameter for the clinical management of these pathologies in Brazil. **Objective:** To identify and analyze the epidemiological profile of deaths by residence caused by inflammatory polyneuropathies. **Methods:** This is an ecological, cross-sectional, descriptive and analytical study, with a quantitative approach, carried out by surveying secondary data available on the DATASUS electronic platform, about the epidemiological profile of deaths due to inflammatory polyneuropathies from 2018 to 2022. For the data analysis, the number of deaths by sex and color/race was considered. Then, the information was organized and tabulated in the Microsoft Excel 2021 software. **Results:** Between 2018 and 2022, 1,330 deaths were recorded due to inflammatory polyneuropathies, with the majority in 2022, with ¼ of the cases, followed by 20% in 2019, demonstrating an increase in occurrences. Deaths were predominant among males, with approximately 62% (824) of notifications, while only 38% were among women. Furthermore, the white color/race was the most affected among both sexes, accounting for 52.5% of the total, followed by 37% of browns and 7% of blacks. There were only 7 cases among yellow people and 4 among indigenous people. **Conclusion:** Therefore, based on the data made available by DATASUS, it is possible to conclude that there was an increase in the number of deaths due to inflammatory polyneuropathies throughout the analyzed period. Furthermore, it was found that males and white color/race had higher death rates. Therefore, the analysis of these data reinforces the importance of better targeting of treatment, since the evolution of this disease can cause physical and functional limitations, as well as early diagnosis, with the aim of reducing cases of death.

Epidemiological analysis of deaths due to tuberculosis of the central nervous system in Brazil by geographic regions from 2013 to 2023

Vitor Hugo Bombarda Barros[1], Camila Vitória de Oliveira Zukovski[1], Maria Thereza Antoniolli Silva Sá Rosa[1], Bruna Mendes Ribeiro[1], Ana Beatriz Trentin de Moura Zago[1], Isabela Lopes Silva[1]

[1]Universidade de Araraquara, Araraquara SP, Brazil.

Correspondence: Vitor Hugo Bombarda Barros; Email: vitorhugobarros508@gmail.com.

Background: Tuberculosis, caused by Mycobacterium tuberculosis, constitutes a public health emergency in Brazil. Among the extrapulmonary manifestations of the disease, approximately 5-10% correspond to tuberculosis of the central nervous system (CNS-TB), which presents high morbidity and mortality rates. CNS-TB can develop from hematogenous dissemination or the rupture of subependymal or meningeal tuberculous foci. Its main clinical-pathological forms are tuberculous brain abscess/tuberculoma, spinal tuberculosis/tuberculous myelitis, and tuberculous meningitis. Some described complications of the condition include hydrocephalus, visual loss, focal neurological deficits, vasculitis, stroke, hemiplegias, cerebral edema, tuberculoma or abscess-induced seizures, diabetes insipidus, and syndrome of inappropriate antidiuretic hormone secretion. **Objective:** To gather, interpret, and discuss data regarding the number of deaths due to neurotuberculosis in the five regions of Brazil (North, Northeast, Central-West, South, and Southeast) from 2013 to 2023 and relate them to public health. **Methods:** A cross-sectional study was conducted. Data on deaths due to tuberculosis of the central nervous system from 2013 to 2023 were obtained from the "Sistema de Informações Hospitalares do SUS" (SIH/SUS) linked to DATASUS. In addition, a brief literature review on the pathology in question was performed. For this, the descriptors "Mycobacterium tuberculosis" and "Tuberculosis, Central Nervous System" were used, obtained with the help of the DeCS/MeSH platform. The database used was PubMed. Articles published between 2022 and 2024 were included. Articles that did not fall within this period and did not provide clear contributions to the study were excluded. Of the 161 articles found in the search, 9 articles were used to compose the brief review. Finally, a second search was conducted in the PubMed database using the descriptors "Brazil" and "Tuberculosis" for the period from 2013 to 2024 to enhance the discussion and findings. The data were presented according to regions of the Brazilian territory through tabular and graphical representation. **Results:** A total of 340 deaths due to tuberculosis of the central nervous system were recorded in Brazil over the 11 years studied. The Southeast region had the highest total number of deaths (170), followed by the Northeast (63), South (57), North (38), and Central-West (12). The year 2022 had the highest absolute number (48), while 2014 and 2015 were the least significant, with 19 deaths each year. The overall average number of deaths was approximately 31 per year. **Conclusion:** The distribution of deaths due to neurotuberculosis was heterogeneous across the territory. Factors such as the COVID-19 pandemic, socioeconomic situation, and underreporting of cases were identified as key influences on the data. The study provided a broad epidemiological view of the disease-related deaths in the country.

https://doi.org/10.5327/CBN240654

Epidemiological analysis of deaths from neuromuscular junction and muscle diseases from 2018 to 2022

Matheus Prado dos Santos[1], Paola Carolina Santos Foinkinos[1], Suzana Gomes de Oliveira[1], Hellen Jost Evaldt[2], Bruna Martyres Gueiros[1], Maria Eduarda da Silva Santos[1], Zulma Catarina dos Santos Silva[1], Matheus de Carvalho Alves[1], Louise Araújo Corrêa[1], Larissa Ádila Desireé Vieira de Andrade Duarte[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil. [2]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Matheus Prado dos Santos; Email: imatheusprado@gmail.com.

Background: Neuromuscular diseases encompass several pathologies caused by involvement of the motor unit, which mainly encompasses the motor neuron, the neuromuscular junction and skeletal muscle tissue. Furthermore, the age range and mode of onset of these diseases are essential information for evaluation and differential diagnosis in adults and children, due to variable clinical manifestations, such as weakness, changes in reflex movements, spasticity, among others. Therefore, this study seeks to allow a better understanding of the epidemiological profile of patients affected and who died from neuromuscular junction diseases. **Objective:** To identify and analyze the epidemiological profile of deaths caused by neuromuscular junction diseases. **Methods:** This is an ecological, cross-sectional, descriptive and analytical study, with a quantitative approach, carried out by surveying secondary data from SIHSUS, available on the DATASUS electronic platform, referring to the number of deaths due to neuromuscular junction diseases in the period 2018 to 2022. To analyze the cases, the variables year, region, race/color and gender were considered, over the subsequent 5 years. Then, the data was organized and tabulated in the Microsoft Excel 2021 software. **Results:** Between 2018 and 2022, 9,543 deaths were recorded due to myoneural junction and muscle diseases, with a predominance of those in the Southeast (48%), Northeast (19.5%) and South (18%), and low occurrences in the Center -West (8%) and North (4.5%). Of these, 1,884 cases occurred in 2018, 2,040 in 2019, 1,614 in 2020, 1,939 in 2021 and 2,066 in 2022, showing a progressive increase in deaths, despite the drop in 2020. White color/race was predominant, representing 65% of notifications , followed by brown with approximately 27% and black with 4.5%; the yellows presented only 50 cases and the indigenous, 25. There was also a majority of males, with 64.5% of deaths in the period analyzed. **Conclusion:** Therefore, we observed a progressive increase in the number of deaths due to this disease, with a predominance in the southeast region compared to others. Additionally, there was a higher prevalence of deaths among white individuals and males. These results underscore the need for a more targeted approach in treating these conditions, considering their implications on patients' quality of life and mortality. The importance of early diagnosis is also highlighted to mitigate the adverse effects of these diseases and reduce the number of deaths.

https://doi.org/10.5327/CBN240655

Epidemiological analysis of epilepsy cases in the state of Pará between 2018 and 2022: an ecological study

Walter Oliveira Verissimo[1], Leonardo Yuji Nihira Alencar[1], Dangilla Ribeiro dos Santos[2], Luiz Carlos Figueiredo Filho[2], Marcelle Rodrigues Carneiro de Souza Reis[3]

[1]Universidade Federal do Pará, Belém PA, Brazil. [2]Universidade do Estado do Pará, Belém PA, Brazil. [3]Centro Universitário do Planalto Central Apparecido dos Santos, Brasília DF, Brazil.

Correspondence: Walter Oliveira Verissimo; Email: walterverissimo17@gmail.com.

Background: Epilepsy affects 1% of the world's population and is characterized by epileptic seizures, the result of unbalanced neuronal discharges. There are two main types: focal and generalized, as well as seizures of unknown origin. Genetic predisposition is significant. Diagnosis is clinical and based on neurological tests. The WHO estimates that there are 65 million cases worldwide, with 5 million new cases every year, with a higher prevalence in low-income countries due to endemic diseases and lack of infrastructure. In Brazil, 2% of the population has epilepsy, with 150,000 new cases a year and an increase in mortality in the North and Northeast regions. **Objective:** To analyze the distribution of epilepsy cases in Pará between 2018 and 2022. **Methods:** This is a quantitative ecological study. We used data from the Notifiable Diseases Information System (SINAN) for the state of Pará between 2018 and 2022. The variables included were: sex, municipalities of hospitalization, race, age group, health regions and deaths. The data was tabulated using TABNET and analyzed using Microsoft Excel 2016. The non-parametric chi-square statistical test was applied, for equal expected proportions, with a significance value of 0.05%, with a 95% confidence interval (CI), as well as the relative risk value for comparing the risk of developing the outcome, both calculated using GraphPad Prism 8 software. **Results:** 5114 cases of epilepsy were analyzed, with 111 evolving to death and a 2.1% mortality rate. About gender, 55.73% of cases were in men (RR 1.16, 1.15 - 1.22, p<0.0001). Concerning race, brown people accounted for 62.59% of cases, followed by the group with no information, with 32.21%. Regarding age, individuals aged between 1 and 4 years had more cases reported, with 1002 cases or 19.59% of the total (RR 2.49, 2.22 - 2.80, p<0.0001). In addition, about the number of deaths compared between the sexes, 58.55% of the total was male (RR 1.26, 0.92 - 1.72, p=0.162). As for the analysis by health region, the Araguaia and Carajás regions stood out, with 17.44% and 16.41% of the cases. **Conclusion:** Epilepsy is more prevalent in the South, Southeast and Metropolitan regions of Belém, in men and children aged 1 to 4, groups most affected by the endemic aspects of the region. The data in this study can help reinforce health actions aimed at planning and implementing strategies for epidemiological surveillance and health policies directed at epilepsy, especially in the groups most affected by the disease. A limitation of this study is the possibility of underreporting of data. Actions are therefore needed to improve the updating of data, allowing for more work that can contribute to planning disease control and improving state indicators.

https://doi.org/10.5327/CBN240656

Epidemiological analysis of Hansen's disease in the pediatric population in the state of Goiás: from 2010 to 2023

Victor Pedrosa Ferreira de Souza[1], Camila Pugliesi de Figueiredo[1], Amanda Mendes Santos[1], Michelle Oliveira Teixeira[1], Elzilaine Domingues Mendes[1], Priscila Ariede Petinuci Bardal[1]

[1]Universidade Federal de Catalão, Catalão GO, Brazil.

Correspondence: Victor Pedrosa Ferreira de Souza; Email: vvictor.pedrosa.vs@gmail.com.

Background: Hansen's disease or leprosy is an infection caused by the Mycobacterium leprae that can affect peripheral nerves, cause severe neural damage and lead to permanent grade-2 disability. Children are particularly vulnerable not only due to their immature immune systems, but also due to the possible psychological and emotional damage as a result of the stigma associated with this disease. **Objective:** To describe the profile of the pediatric population with leprosy in the state of Goiás in Brazil. **Methods:** A retrospective descriptive epidemiological study was carried out on the notified cases of leprosy in Goiás, between 2010 and 2023. The data was collected from the Brazilian Unified Health System (SUS) databases. The age group analyzed was from 0 to 14 years. The variables evaluated were: age, sex, skin color, operational class, number of multidrug therapy (MDT) doses and exit type. **Results:** Between 2010 and 2023, 978 cases were notified in the 0-14 age group. In 2015, there were 108 cases and in 2016, 64. In 2019, the number of cases was 53. In 2020, there was a significant drop to 34 cases. This data kept decreasing to 27 cases in 2021, 15 in 2022 and 6 in 2023. Regarding the age groups, in this period, 37 cases were reported in children aged 0-4, 292 in children aged 5-9 and 649 in people aged 10-14

years. More boys (500) were affected than girls (478). The majority of the individuals had brown skin color (62.37%). About the operational class, 573 individuals were diagnosed with multibacillary (MB) and 399 with paucibacillary (PB) leprosy. Of the filled data with number of MDT doses, 9.9% of PB and 23.4% of MB patients didn't complete the recommended treatment. About the type of exit, 779 were cured, 75 were transferred, 33 were misdiagnosed, 27 dropped out and 2 died. **Conclusion:** This study found that the number of notified cases has been decreasing since 2015, with an accentuated drop since the pandemic started in 2020. It's not possible to determine if this tendency is due to the reduction of the infection itself or if there has been an underreporting of new cases. However, the majority of cases are notified when the disease is already in an advanced stage, which is concerning. In addition, there is a noteworthy percentage of uncompleted treatment. Hence, prevention, early detection and treatment adherence are urgent to control this disease, especially considering Primary Care and the Family Health Strategy as a public policy.

https://doi.org/10.5327/CBN240657

Epidemiological analysis of hospitalizations due to Alzheimer's disease in the Brazilian population between 2019 and 2023

Yasmim Melo Costa de Azevedo[1], Raul Pereira Bassotto Franco[2], João Pedro Rosa Barroncas[3], Marcelly Silva dos Santos Brito[4], Maria Regina Saddi Guerra[5], Cayara Mattos Costa[6]

[3]Universidade Federal do Amazonas, Manaus AM, Brazil.
[4]Universidade Federal de Pernambuco , Caruaru PE, Brazil.
[5]Universidade Católica de Brasília, Brasília DF, Brazil.
[6]Universidade Federal do Maranhão, São Luís MA, Brazil.

Correspondence: Yasmim Melo Costa de Azevedo; Email: yaxmelo@outlook.com.

Background: Alzheimer's disease (AD) is a neurodegenerative condition that leads global dementia cases - accounting for 80% of the total. Its pathophysiology is closely associated with aging and it is considered a progressive, incurable disease. The memory, reasoning, and stimulus interpretation capacities, for example, of AD patients are compromised, requiring hospitalization due to complications that arise in their lives. According to the Ministry of Health, the number of hospitalizations due to AD in Brazil increased by 88% between 2010 and 2019. **Objective:** To analyze epidemiological data on hospitalizations for Alzheimer's Disease in Brazil between 2019 and 2023. **Methods:** Cross-sectional, quantitative, descriptive and observational research, with data from January 2019 to December 2023, collected in the SUS Hospital Information System, on the DATASUS platform. The total number of hospitalizations for Alzheimer's Disease were analyzed according to the International Classification of Diseases (ICD G30) in Brazil, considering the epidemiological variables: total hospitalizations per year, region, age group, sex, color/race, character of service and average length of stay in days. **Results:** In the period between 2019 and 2023, 7.866 hospitalizations for Alzheimer's were recorded in Brazil. The year 2023 had the highest number of hospitalizations, with 2.121 cases, while 2020 had the lowest number, with 1.212 cases. Between 2019 and 2020, there was a significant reduction of approximately 24%, possibly related to the COVID-19 pandemic and underreporting of cases. However, during most of the five-year period (2019-2023), an increase in the number of hospitalizations for Alzheime's was observed, with an average annual growth of 6%. In relation to the regions, the Southeast (47%) and the South (25%) were the most affected, while the North (3%) least. The majority of patients were women (66%), while men represented 34%. With regard to color, white people (n=3,977) and mixed-race people (n=2,079) were the most affected by the disease. Regarding the nature of these hospitalizations, emergency cases were the most significant, corresponding to 80% of the total, while elective cases represented 20%, with an average stay of 19.6 days. **Conclusion:** Hospitalizations for AD in Brazil showed a successive increase between 2020 and 2023, predominating in the Southeast region, on an urgent basis, and mainly affected white women aged 80 years or older. Therefore, in view of the growth in the incidence of AD and the number of elderly people in the country, it is urgent to invest in public policies focused on prevention and care strategies aimed at AD.

Epidemiological analysis of hospitalizations due to multiple sclerosis in the Northeast of Brazil from 2018 to 2023

Rosa Carolina Santos de Oliveira[1], Álvaro Henrique de Moraes Santos[2], Daniela Meira dos Santos[1], Karolyne Vieira Mota[1], Mariana Mota Alves[2], Giovanna dos Reis Martins Barros[1], Helton Benevides Santana de Oliveira[2]

[1]Universidade Tiradentes, Aracaju SE, Brazil.
[2]Universidade Federal de Sergipe, Aracaju SE, Brazil.

Correspondence: Rosa Carolina Santos de Oliveira; Email: rosa.oliveira@souunit.com.br.

Background: Multiple sclerosis (MS) is an immune-mediated inflammatory demyelinating disease and is the most common demyelinating disease of the central nervous system (CNS). Among CNS pathologies, MS is one of the most recurrent cause of permanent disability in young adults, second only to traumatic brain injury. The incidence of MS varies due to environmental, geographical, population, gender, and age factors. Considering this, it is essential to understand the local panorama of this pathology to make advances in this field. **Objective:** Thus, the present study aims to identify the epidemiological profile of hospitalizations due to MS in the Northeast of Brazil, with the purpose of contributing to the development of effective therapeutic and preventive measures against this scourge. **Methods:** This is a multiple-group study with a quantitative, descriptive, and exploratory approach. Secondary data were collected through the hospital information system provided by DATASUS (SIH/SUS). The sample covers records between January 2018 and December 2023 in the Northeast region of Brazil. The analysis variables included age group, gender, and race. **Results:** During the analyzed period, between January 2018 and December 2023, there were 2,633 recorded hospitalizations for Multiple sclerosis in the Northeast region of the country. There was an increase in the number of hospitalizations per year, from 232 in 2018 to 858 in 2023, with the latter being the year with the highest number of cases. Regarding race, 184 (6.9%) hospitalized patients were white, 42 (1.59%) were black, 1,495 (56.77%) were brown, 63 (2.39%) were yellow, and 849 (32.24%) were not reported. Females accounted for 70.5% (1,857) of the hospitalizations, while males accounted for 29.5% (776). Considering the age group, 192 (7.29%) people aged 0 to 19 years were hospitalized, 704 (26.73%) were aged 20 to 29, 771 (29.28%) were aged 30 to 39, 550 (20.88%) were aged 40 to 49, 265 (10.06%) were aged 50 to 59, and 150 (5.69%) were aged 60 or older. **Conclusion:** In the present study, there was an increase in hospitalizations due to multiple sclerosis in the Northeast of Brazil. The profile of brown-skinned patients presented the highest numbers. The lowest numbers were among black individuals. Hospitalizations occurred mainly among females and in the age group between 20 and 39 years, with a slight predominance in the 30 to 39 years group. Patients at the extremes of age, such as children up to 4 years old and elderly individuals between 70 and 79 years old, accounted for few hospitalizations. Given these findings, further studies are needed to analyze the relationships of multiple sclerosis, its prevalence, and its influence on the conduct of the highlighted profiles.

[8]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Laysa de Souza Maia; Email: laysamaia1503@gmail.com.

Background: According to Walker et al. (2023), facial paralysis (FP) has an incidence of 10 to 40 cases per 100,000 inhabitants. Facial paralysis and paralytic syndromes are characterized by neurological conditions caused by viral infections or immunological diseases. However, FP occurs due to edema in the 7th cranial nerve. In contrast, Unspecified Paralytic Syndrome is characterized by paralysis in specific parts of the body without an identified cause. **Objective:** To analyze the distribution of hospital admission authorizations (AIH), average length of stay, and mortality rates among the five Brazilian macro-regions from 2019 to 2023 concerning Facial Paralysis and other paralytic syndromes. **Methods:** This is a descriptive and cross-sectional epidemiological study based on data verified from DATASUS from 2019 to 2023. The analyzed variables included hospitalizations, approved AIH, average length of stay, and mortality rate according to demographic regions, as well as sex and ethnicity. **Results:** Data analysis from 2019 to 2023 revealed a total of 117,315 AIH across Brazil, with the Southeast Region having the highest number of hospitalizations at 75.6% and the North Region at only 0.80%, suggesting that the distribution and quality of services offered are related to regional infrastructure. In 2019, Brazil recorded 8,677 hospitalizations and 25,017 approved AIHs, representing the highest number recorded during the studied period. However, in 2020, there was a significant reduction in these numbers, with only 6,321 hospitalizations and 22,292 approved AIHs; this decrease can possibly be explained by the underreporting of cases due to the COVID-19 pandemic. The total average length of stay was 71.5 days, with the Southeast Region showing data above this average at 133.5 days. The North Region had the lowest average length of stay at 10.0 days but had the second-highest mortality rate at 2.95%. The South Region had the highest mortality rate, while the Northeast Region had the lowest at 0.93%, possibly associated with better healthcare service conditions in this area. Males had the highest number of hospitalizations (24,231) and approved AIHs (65,406), while females had the highest average length of stay (85.5 days) and mortality rate (2.02%). The ethnicity with the most hospitalizations was Pardo (mixed race) with 9,934 cases but had the lowest average length

of stay at 65.3 days. **Conclusion:** This study highlights the importance of adequate and accessible healthcare infrastructure for the management of FP and paralytic syndromes in Brazil, fostering improvements in service quality and reducing disparities. Furthermore, it is evident that there is a lack of studies in Brazil specifically investigating the prevalence and incidence of facial paralysis and paralytic syndromes in the country.

https://doi.org/10.5327/CBN240661

Epidemiological analysis of hospitalizations for microsurgery for intracranial tumors in Brazil between the years 2013 and 2022

Hálisson Ferreira Freitas Filho[1], Izabella Carolline Menescal Ferreira[1], Igor Moreira Miguez Godoy[2] , Antônio Marcos da Silva Henriques[1], Luan Víctor Silva Ribeiro[3] , João Victor Souza de Barros[1], Larissa Suzan Basilio e Silva[1], Kaliana Kennedy Oliveira Calixto[1], Felipe José Silva e Silva[1], Nathália Coimbra Coêlho[1]

[3]Afya Faculdade de Ciências Médicas, João Pessoa PB, Brazil.

Correspondence: Hálisson Ferreira Freitas Filho; Email: halisson.filho@ics.ufpa.br.

Background: Microsurgery aims to obtain a histological diagnosis through the removal of intracranial tumors with the assistance of an intraoperative microscope, which provides illumination and magnification, allowing for the resection of tumors in critical areas in an attempt to restore neurological function. **Objective:** To perform a descriptive analysis of the epidemiological profile of hospitalizations for microsurgery for intracranial tumors in Brazil between 2013 and 2022. **Methods:** This is a descriptive, analytical, and retrospective study with a quantitative approach. Data were obtained from the Department of Informatics of the Unified Health System (DATASUS). Information was accessed through the Hospital Information System of the Unified Health System (SIH/SUS) and Hospital Production of the SUS. Procedures with the code "0403030145," corresponding to microsurgery for intracranial tumors, performed between January 2013 and December 2022, were included. The variables analyzed included the number of hospitalizations, length of stay, and total cost, analyzed over time and according to geographic region. **Results:** According to data from the Ministry of Health, there were 21,336 hospitalizations through SUS for intracranial tumor microsurgery in Brazil between 2013 and 2022. The number of hospitalizations increased from 2013 to 2015, decreased in 2016, remained relatively constant in 2017 and 2018, and increased again in 2019 and 2021, with a significant reduction in 2020. The Southeast and Northeast regions recorded the highest number of hospitalizations, with the Southeast region showing the greatest variation over the years. In 2013, the longest average length of stay was 16.3 days. The Northern region had the longest average length of stay at 17.9 days, while the Southeast region had the shortest at 13.8 days. The total resources allocated to the procedure were R$ 122,379,265.02 between 2013 and 2022. The Southeast region accounted for the majority of expenditures, corresponding to 42.60% (R$ 52,135,877.18), followed by the Northeast with 25.38% (R$ 31,067,048.82), South with 17.73% (R$ 21,702,877.70), North with 8.47% (R$ 10,373,860.39), and Midwest with 5.80% (R$ 7,099,600.93). **Conclusion:** It is concluded that the hospitalization rate varies significantly among the regions of the country, with a higher prevalence and monetary investment in the Southeast and Northeast regions, while the Midwest region presents the lowest rates in both aspects. The Southeast region records the shortest average length of stay, while the Northern region presents the longest. These data reveal an imbalance in the distribution of financial and structural resources in Brazil.

Epidemiological analysis of hospitalizations from viral encephalitis in Brazil from 2019 to 2023: an ecological study

Leonardo Yuji Nihira Alencar[1], Janaína de Oliveira e Castro[2], Marcelle Rodrigues Carneiro de Souza Reis[3], Walter Oliveira Verissimo[1]

[1]Universidade Federal do Pará, Belém PA, Brazil.
[2] Universidade Federal do Amazonas, Manaus AM, Brazil.
[3]Centro Universitário do Planalto Central Apparecido dos Santos, Brasília DF, Brazil.

Correspondence: Leonardo Yuji Nihira Alencar; Email: leo1820.alencar@gmail.com.

Background: Viral encephalitis is inflammation of the brain that occurs when a virus directly infects the brain or when a virus, vaccine or other factor activates the inflammation. The mortality rate varies with the cause, but the severity of the epidemic resulting from the same virus varies over the years. Permanent neurological deficits are more likely to occur in patients who survive severe infection, which occurs mainly in the elderly, children and the immunodeficient. Therefore, given the considerable increase in cases, it is essential to analyze current data on the distribution of the disease to improve prevention actions and reduce mortality. **Objective:** To analyze the temporal distribution of hospitalizations and deaths from viral encephalitis between 2019 and 2023 in Brazil. **Methods:** This is an ecological, descriptive and quantitative study, which used data from the SUS Hospital Information System (SIH/SUS) tabulated by the Department of Informatics of the Unified Health System (DATASUS). Data was extracted between 2019 and 2023 from the Brazilian territory. The variables included were age group, gender, color/race, hospitalizations and deaths. The information was tabulated using TABNET and analyzed using Excel 2016. **Results:** In the period analyzed, there were 9818 hospitalizations and 497 deaths from viral encephalitis, both with peaks in 2019, corresponding to 24.8% of hospitalizations and 24.7% of deaths. In addition, 2023 had a considerable number of hospitalizations (2069), higher than previous years, with 1977 hospitalizations in 2022, 1647 in 2021 and 1689 in 2020. As for age group, throughout the period, children aged 1 to 4 had the highest number of hospitalizations, totaling 1784, with a peak in 2022 (433 cases), however, about the number of deaths, the number of occurrences was highest in the 30 to 34 age group, with 45 deaths in total and a peak in 2023 (11), followed by the 80 and over age group, with 39 deaths and a peak in 2019 (13). Males had the highest number of hospitalizations (58.3%) and deaths (53.4%), showing higher values than females in all years, with peaks in 2019, corresponding to 24.4% of deaths and 25.3% of hospitalizations for this group in the period. As for race, brown people had a higher number of hospitalizations (51.1%) and deaths (43.6%), with the peak in 2023 (26.1% of all hospitalizations for this group in the period). **Conclusion:** According to the data analyzed, the 1-4 age group had the highest number of hospitalizations, as well as males and brown people, groups that also had the highest number of deaths. A limitation of the study is the possibility of underreporting and patients being classified in incorrect groups. Further analysis of the distribution of viral encephalitis is therefore needed to integrate improvements in the control and prevention of the disease, to reduce the number of deaths resulting from it.

https://doi.org/10.5327/CBN240663

Epidemiological analysis of intracranial hemorrhage cases in Goiás over the past five years

Gustavo Hayasaki Vieira[1], Giovana de Oliveira Araújo[1], Gustavo Cartaxo de Sousa Melo[1], Isabela Maciel Mesquita[1], Milena Almeida Barbosa[1], Paulo André Silva Miranda[1], Paulo Sérgio Machado Diniz[1], Rafaella Rodrigues de Freitas Vieira[1], Samira Dionísio Maia[1], Valentina Melo Rosa Centofanti[1]

[1]Pontifícia Universidade Católica de Goiás, Goiânia GO, Brazil.

Correspondence: Gustavo Hayasaki Vieira; Email: gushayasaki@gmail.com.

Background: Intracranial hemorrhage constitutes a serious clinical condition that can arise from trauma, hypertension, and vascular malformations. Due to its severity, the disease ranks among the leading causes of morbidity and mortality in Brazil, resulting in motor and cognitive dysfunctions that significantly impact the daily lives of affected patients. Thus, an epidemiological analysis in the state of Goiás over recent years is essential to better understand the factors contributing to this scenario and to enhance prevention, diagnosis, and treatment measures. **Objective:** To analyze the epidemiological profile of patients affected by intracranial hemorrhage from 2019 to 2023 in the state of Goiás. **Methods:** This is an ecological, descriptive, retrospective, and quantitative study using data from the Hospital Information System (SIH/SUS) provided by the Department of Information Technology of the Unified Health System (DATASUS), focusing on patients with intracranial hemorrhage in Goiás from 2019 to 2023. Filters applied included hospital morbidity within the SUS, geographical location, Central-West region, federal unit (Goiás), ICD-10 code (intracranial hemorrhage), processing year, age group, race/ethnicity, gender, number of hospitalizations, and deaths. Data were tabulated in Excel and descriptive statistics were conducted using R 4.40 with RStudio 2024.04.1 + 748. This study did not require ethics committee approval as it utilized publicly available secondary data. **Results:** During the study period, 868 deaths due to intracranial hemorrhage were confirmed, with an average annual incidence of 166.8 cases (±19.6). Individuals of mixed race were predominantly affected, comprising 78.34% of total deaths. The age group most vulnerable to the disease was 60-69 years, accounting for 198 deaths. Regarding gender, the average number of deaths was 87.8 (±19.7) for males and 79 (±2.54) for females. Additionally, the year 2021 recorded the highest number of hospitalizations, totaling 621 cases; whereas 2019 had the lowest with 462 hospitalizations within the analyzed period. Moreover, both hospitalizations and deaths showed an increasing trend until 2021, followed by a decline in subsequent years: 617 cases in 2022 and 567 in 2023. Furthermore, the age group most frequently hospitalized was 50-59 years (21%). **Conclusion:** The majority of intracranial hemorrhage deaths occur among individuals of mixed race. Additionally, males exhibit a higher mortality rate compared to females, and the disease has shown a declining trend in recent years. Individuals aged 60 to 69 years are the most vulnerable, resulting in higher mortality rates, while those aged 50 to 59 years experience the highest frequency of hospitalizations due to intracranial hemorrhage. Therefore, this study provides data that can be used as a basis for prevention strategies carried out by higher academic institutions and by the State Health Department.

https://doi.org/10.5327/CBN240664

Epidemiological analysis of meningococcal disease in children up to 14 years old

Samara Brissi Benito da Silva[1], Gabriel Vergolino Eleres[2], Amábile Cirilo da Silva[3], Rafaella Ferreira dos Santos[4], Isabela Nishimura Megiani[5], Hévila Ferreira Gomes Medeiros Braga[6]

[1]Universidade de Mogi das Cruzes, Mogi das Cruzes SP, Brazil.
[2]Fundación Barceló, Buenos Aires, Argentina.
[3] Universidade Federal de Juiz de Fora, Juiz de Fora MG, Brazil.
[4]Universidade Santo Amaro, São Paulo SP, Brazil.
[5]União das Faculdades dos Grandes Lagos, São José do Rio Preto SP, Brazil.

[6]Universidade da Integração Internacional da Lusofonia Afro-Brasileira, Redenção CE, Brazil.

Correspondence: Samara Brissi Benito da Silva; Email: samarabrissi@gmail.com.

Background: Meningococcal disease (MD) is defined as a severe infection caused by the bacterium Neisseria meningitidis (meningococcus), which can lead to inflammation of the meninges (meningococcal meningitis) and bloodstream infection (meningococcemia), and is transmitted by the respiratory routes, such as secretions and droplets. Worldwide, an estimated 500,000 cases and 50,000 deaths due to MD occur annually, and in Brazil, it is considered endemic. In addition, the disease has 12 serogroups, with serogroups A, B, C, W, Y, and X being the most prevalent in reported cases. **Objective:** To analyze the epidemiological profile of Meningococcal Disease according to its serogroups between 2014 and 2023, among children up to 14 years of age. **Methods:** A descriptive ecological study conducted using data from the Notifiable Diseases Information System (SINAN). Confirmed cases and deaths from meningococcal meningitis (MM) with meningococcemia (MCC) in the population up to 14 years old were considered from 2014 and 2023. The variables used were: confirmed cases, deaths, age group, race/ethnicity, serogroup, and Brazilian region. The data was analyzed descriptively and organized in Microsoft Excel spreadsheets. **Results:** In the period analyzed, 1,266 cases of meningococcal disease were identified in Brazil. It was found that the disease predominated in 555 cases (43.8%) in individuals identified as white, aged 1 to 4 years (33%), located in the Southeast region (67%), with the majority of cases resulting in hospital discharge (77.6%). Among the analyzed serogroups, type B was the most prevalent with 338 cases (26.6%), and also resulted in the highest infant mortality among all serogroups with 66 deaths (52.1%). However, the vaccine against serogroup B is not provided by the Brazilian Unified Health System (SUS), accessible only through private healthcare service. This highlights a potential correlation between the increased number of cases and the higher infant mortality rate associated with this serogroup. **Conclusion:** The data shows the importance of recognizing Meningococcal Disease according to the epidemiological profile of the studied population and emphasize the need of developing strategies for disease control. The unavailability of the vaccine for serogroup B through SUS is concerning for public health in Brazil, particularly due to its prevalence in reported cases and deaths among children. Moreover, it is essential to raise public awareness about the disease and vaccination for prevention, which has been shown to be positive in the serogroups where vaccines are available through SUS, as well as early diagnosis and treatment, as indicated in the literature, have shown improved prognosis.

https://doi.org/10.5327/CBN240665

Epidemiological analysis of meningoencephalic tuberculosis in vulnerable populations in Brazil: 2014-2023

Helmut Kennedy Azevedo do Patrocínio[1], Matheus Procópio Guimarães[1], Tiago Lameque de Sousa e Silva[1], Pedro Henrick Guimarães Carvalho[1], Cláudio de Souza Fernandes Júnior[1], Cláudio de Souza Fernandes[2], Tereza Cristina Batista Dias[1], Maria Eduarda Medeiros Martins[1], Matheus Araújo de Medeiros[1], Iury Hélder Santos Dantas[1]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.
[2]Universidade do Estado do Rio Grande do Norte, Mossoró RN, Brazil.

Correspondence: Helmut Kennedy Azevedo do Patrocinio; Email: hell.kenn@gmail.com.

Background: Meningoencephalic tuberculosis (MTB) is the most severe form of tuberculosis (TB), characterized by high mortality and morbidity rates. Risk factors for developing MTB include immunocompromised states, such as chronic steroid use, diabetes mellitus, alcoholism, and, primarily, HIV co-infection. To date, no studies have specifically addressed the risk of developing MTB in the vulnerable populations investigated in this study. **Objective:** Conducting an epidemiological analysis of the health issues associated with the development of tuberculosis in vulnerable populations. **Methods:** A retrospective epidemiological study using data from the Notifiable Diseases Information System to analyze the occurrence of MTB in vulnerable populations - health professionals, persons deprived of liberty (PDL), homeless people (HoP), and immigrants - in Brazil from 2014 to 2023. For each vulnerable population, both descriptive and inferential statistical analyses were performed to assess the occurrence of alcoholism, diabetes, smoking, mental illness, drug use and AIDS. To examine factors associated with TBM, binomial logistic regression analyses were conducted. Data analysis used the statistical software R. **Results:** Of the 5960 identified cases of MTB, 105 occurred in PDL, 102 in HoP, 62 in health professionals, and 31 in immigrants. When comparing MTB with exclusively pulmonary TB in all populations, the presence of AIDS was associated with a significantly higher odds ratio (OR): PDL (OR: 11.8, P<0.001), HoP (OR: 9.71, P<0.001), health professionals (OR: 9.01, P<0.001), and immigrants (OR: 8.53, P<0.001). Although other conditions had high odds ratios, such as mental illness in immigrants (OR: 4.7, P=0.064) and alcoholism in PDL (OR: 1.65, P=0.1) and HoP (OR: 1.4, P=0.2), no statistical significance was achieved. AIDS was the predominant factor in all four populations studied, with the highest proportion observed in the HoP group (75.25%) and the lowest in health professionals (31.15%). In addition, the HoP group showed a high frequency of alcoholism (56.82%), illicit drug use (60.64%) and smoking (41.11%). However, none of these variables was identified as a significant risk factor. **Conclusion:** The results of this study emphasize the importance of investigating the factors associated with the development of MTB in Brazil. AIDS was consistently associated with a higher risk of MTB in all the populations. Conditions such as alcoholism and mental illness also had odds ratios above 1, but did not reach statistical significance. A limitation of this study was the limited sample size, which restricted the development of a more accurate statistical model. Therefore, further research is needed to comprehensively investigate MTB, especially in vulnerable marginalized groups. Understanding the predisposing conditions for the occurrence of MTB is crucial for the implementation of targeted interventions tailored to each vulnerable population.

https://doi.org/10.5327/CBN240666

Epidemiological analysis of migraine hospitalizations in the state of São Paulo from 2019 to 2023: an ecological study

Bruna Ravany Farias Marques[1] , Nicolas Inkei Chiba Frazao[2], Maria Clara Calixto Caetano[3], Giulia Chiavegato Locatelli[4], Beatriz Moraes Florenzano[5], Juliana Braga Rodrigues de Castro[6]

[1]Centro Universitário dos Guarapes, Guanambi BA, Brazil.
[2]Universidade Federal do Pará, Belém PA, Brazil.
[3]Universidade de Ribeirão Preto, Ribeirão Preto SP, Brazil.
[4]Universidade Nove de Julho, São Paulo SP, Brazil.
[5]Faculdade Santa Marcelina São Paulo, São Paulo SP, Brazil.
[6]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Maria Clara Calixto Caetano; Email: maria.caetano@sou.unaerp.edu.br.

Background: Migraine is a chronic neurological disease with a prevalence of 15.2% in Brazil. Clinically, it manifests as recurrent episodes of headache associated with other symptoms, dependent on triggering factors. According to the World Health Organization (WHO), half of the global population experiences headaches at some point in life, with a higher prevalence among females, making it the fourth leading cause of disability in women worldwide. Therefore, migraine needs to be addressed as a public health problem since its occurrence in emergency settings is prevalent and potentially limiting, negatively impacting well-being, quality of life, and imposing a substantial burden on patients and Society. **Objective:** To analyze the epidemiological characteristics of migraine hospitalizations in the state of São Paulo from 2019 to 2023. **Methods:** An ecological, retrospective, and descriptive study was conducted using information on migraine hospitalizations in the state of São Paulo from 2019 to 2023. Information was obtained through consultation with DATASUS. The following variables were analyzed: hospitalizations, age group, sex, race/ethnicity, and year of admission. A descriptive analysis of the data was performed, calculating relative and absolute frequencies for the categorized variables. As this research involved secondary data, there was no need to submit the project for approval by an Ethics Committee. **Results:** A total of 9,316 hospitalizations were analyzed in the state of São Paulo during the period from 2019 to 2023. The results show a higher incidence of cases among females, accounting for 68.9% (n=6,424). The year with the highest number of hospitalizations was 2019, responsible for 22.5% (n=2,101). White individuals were the main group reporting migraine complaints during the analyzed period, representing 58.8% (n=5,476). The predominant age group was 30 to 39 years, accounting for 19.2% (n=1,792). **Conclusion:** The data reveal a significant number of hospitalizations due to migraines in the state of São Paulo in 2019, which decreased and tends to return to previous levels, suggesting impacts of the Covid-19 pandemic, such as underreporting. Additionally, there is a notable incidence of hospitalizations among adults aged 20 to 29 years and among white individuals, representing more than half of the cases. This study has limitations, such as the underreporting of hospitalizations due to the use of a secondary data system and the inability to associate the cause of migraines with the effect of hospitalization. Therefore, more studies are needed to investigate the high number of migraine hospitalizations to understand the real causality in the Brazilian context.

Correspondence: Marcela Cristina de Souza Lemus; Email: marcelalemus47190@gmail.com.

Background: Epilepsy is a chronic neurological disorder characterized by recurrent unprovoked epileptic seizures. Between 2020 and 2023, more than 229,420 individuals were hospitalized due to epilepsy, resulting in significant costs to the Brazilian Unified Health System (SUS) for the management of this condition. **Objective:** To analyze the epidemiological and economic aspects related to the hospitalization costs and mortality rates associated with uncontrolled epileptic seizures in the state of São Paulo. **Methods:** This observational ecological study utilized data obtained from the Hospital Information System (SIH/SUS) provided by the Department of Informatics of the Brazilian Unified Health System (DATASUS). We specifically focused on patients with uncontrolled epileptic

seizures in state of São Paulo from 2020 to 2023. Key variables analyzed included the number of hospitalizations, total costs incurred, mortality rates, and number of deaths per year of management. Ethical approval was not required as the study employed secondary data. **Results:** In the analyzed period, a total of 78,019 hospitalizations due to uncontrolled epileptic seizures were observed in the SUS of the Southeast region, with state of São Paulo accounting for 38,699 of these cases. The average cost per hospitalization in state of São Paulo during this period was R$1,255.06, resulting in a total expenditure of R$48,831,858.69. In 2023 (R$14,467,046.53), the highest total costs of hospitalizations for uncontrolled epilepsy were observed, followed by 2022 with costs amounting to R$13,582,040.96. The year 2022 represented an increase of approximately 30.7% compared to 2021, with a total cost of R$10,393,846.22. There was no significant difference in costs between 2020 and 2021. Over the study period, 1,419 deaths were reported, with mortality rates consistently above 3.0 per 100 hospitalizations: 3.69 in 2020, 3.57 in 2021, 3.58 in 2022, and 3.82 in 2023. Data underreporting is acknowledged as a potential limitation. **Conclusion:** There was an increase in costs, deaths, and hospitalizations due to uncontrolled epileptic seizures in the state of São Paulo between the first and last years analyzed. A significant highlight occurred during the period of the COVID-19 pandemic declared by the World Health Organization, which saw an increase in mortality rates from 2021 onwards and a rise in total annual hospitalization costs from 2020. These findings may be attributed to difficulties in healthcare access, utilization of telemedicine, and heightened fear of severe COVID-19 during the pandemic, exacerbating the epilepsy treatment gap with more hospitalizations, deaths, and costs related to epileptic seizures within the SUS. Furthermore, in 2023, an increase in mortality is observed, potentially linked to the worsening of epileptic seizures following COVID-19 infection.

Epidemiological analysis of patients with epilepsy in Brazil

Luisa Maria Resende Morais[1], Gleison Carlos Arantes Filho[1], Leonardo Brandão Barreto[1]

[1]Universidade Federal de Ouro Preto, Ouro Preto MG, Brazil.

Correspondence: Luisa Maria Resende Morais; Email: luisamresendem@gmail.com.

Background: Epilepsy is a disease characterized by a chronic predisposition of the brain to generate epileptic seizures, whose underlying causes include structural lesions, genetic/metabolic alterations and infectious/autoimmune diseases, and is associated with higher mortality, psychiatric comorbidities and psychosocial problems. **Objective:** To analyze hospital characterization, clinical outcome and cost-effectiveness for patients with epilepsy in Brazil. **Methods:** An observational and retrospective study using data obtained from the Hospital Information System of the Unified Health System, between January 2014 and December 2023, with the following variables: hospitalizations, average length of stay, average cost, mortality rate, gender and age group. Descriptive and inferential statistical analysis was used. **Results:** The most affected profile was males (57.63%) and those aged between 1 and 4 years (16.27%) and 50 to 59 years (10.44%). In the last 10 years, 557,829 hospitalizations for epilepsy were recorded, most of them in the Southeast (42.77%). All regions of Brazil saw a significant increase in the number of hospitalizations, with the highest increase (59.81%) in the Northeast (p=0.001) and the lowest (10.59%) in the Southeast (p=0.012). The average hospital stay in the country was 6 days, with an increase in all regions, however, only in the Northeast, South and Midwest was the increase statistically significant (p<0.05). The biggest increase was in the Northeast, which went from 5.4 days in 2014 to 6.8 in 2023. The average cost to the Brazilian health system was R$848.41, and increased significantly over the period considered in all regions, especially in the Northeast, with an increase of 58.68% (p=0.025). Finally, the mortality rate from epilepsy in the country was 2.48 per 100 inhabitants, with the highest average in the Northeast (2.88) and the lowest in the South (1.82). There was an increase in the mortality rate in all regions of Brazil, with statistically significant increases in the North, Southeast and South, with increases of 69.28%, 47.14% and 41.29%, respectively. **Conclusion:** Epilepsy mainly affects children and the elderly, and is the main cause of hospitalization in children. The increase in average hospital costs is associated with treatment using new generations of antiepileptic drugs, the request for imaging tests and the use of specialized teams, which are costly resources. The increase in the mortality rate can be explained by the increased prevalence of the disease, the significant incidence of infectious diseases of the nervous system related to the etiology of epilepsy in the country and the still limited access to specialists and appropriate treatment. The findings of this study reveal regional disparities, highlighting the need for differentiated approaches to the management of epilepsy in different regions of the country, and underscore the importance of effective interventions to improve its prognosis in Brazil.

Background: Epilepsy is the main neurological condition that affects the pediatric age group. Its occurrence is significant in Brazil, with a total of 215,332 hospitalizations in the last 10 years. This condition is one of the most frequent complaints in pediatric emergency care, representing 1 to 5% of all visits. It is known that up to 10% of the population experiences at least one epileptic seizure by the age of 16. Understanding the epidemiology of pediatric epilepsy in São Paulo is limited. This analysis is essential to guide health policies and improve the treatment of this condition, aiming for a better quality of life for affected children. **Objective:** To describe the epidemiological profile of epilepsy among pediatric patients in the state of São Paulo from 2014 to 2023. **Methods:** A descriptive ecological study carried out through data collection from the SUS Hospital Information System (SIH/ SUS). The study population includes hospitalization for epilepsy in pediatric patients (from 0 to 14 years old) reported in the state of São Paulo between 2014 and 2023.The following variables were researched: age group,gender and color race. **Results:** Out of a total of 215,332 hospitalizations notified in Brazil during the period evaluated,the state of São Paulo accounted for 41,225 hospitalizations, representing approximately 20% of all cases. The most affected age group was from 1 to 4 years, with 17.209 hospitalizations, followed by 5 to 9 years, 1 year or younger and 10 to 14 years, with respectively 9.370, 7.738 and 6.908 hospitalizations. Regarding gender, there is a prevalence of males across all age groups,totaling 22,786 cases,with the 1 to 4 years age group being the most affected,representing 9736 cases. As for color/race, whites (n=22,304) showed the highest incidence, followed by brown (n=12,075). In all age groups, this pattern remained consistent. However, the numbers for black (n=1253), yellow (n=183) and native people (n=8) were significantly lower compared to the previous ethnicities. **Conclusion:** The study corroborates the existing literature by reinforcing the predominance of pediatric hospitalizations among white male children aged 1 to 4 years.Thus, considering the emerging state in pediatric hospitalizations and the detrimental implications to patients, it is crucial to observe inequalities, identify at-risk groups, and better prepare healthcare professionals to receive these patients. In this regard, the important role of primary care in preventing hospitalizations is highlighted.

Epidemiological analysis of spina bifida in Brazil and of maternal factors

Amanda Mendes Santos[1], Camila Pugliesi de Figueiredo[1], Michelle Oliveira Teixeira[1], Victor Pedrosa Ferreira de Souza[1], Wânia Rezende Lima[1]

[1]Universidade Federal de Catalão, Catalão GO, Brazil.

Correspondence: Amanda Mendes Santos; Email: amanda.mendes@discente.ufcat.edu.br.

Background: Spina Bifida (SB) is a congenital defect resulting from the incomplete closure of the neural tube, between the third and fourth week of pregnancy, being one of the major causes of childhood motor disability. Although there are important genetic patterns that contribute to the prevalence of neural tube defects, it is known that factors, such as folic acid supplementation, are of the utmost importance in their etiology. Therefore, it is evident the need to elucidate what other external variables may contribute to its development. **Objective:** To evaluate infants with SB in Brazil and the maternal epidemiological profile. **Methods:** It's a retrospective descriptive epidemiological study of live births with SB in Brazil, based on data from the Congenital Malformations, Deformities and Chromosomal Anomalies Monitoring Panel. The data from 2014 to 2024 was analyzed, with the results from 2023 and 2024 being preliminary. The variables included were marital status, educational level, month of pregnancy in which prenatal care began and number of prenatal consultations. **Results:** In total, 7593 babies were born with SB. Specifically, there was a prevalence of lumbar SB (588), followed by cervical (425), sacral (370) and thoracic (123). Lumbar SB without hydrocephalus was the most prevalent (390), followed by cervical with hydrocephalus (312), sacral without hydrocephalus (247), lumbar with hydrocephalus (198), sacral with hydrocephalus (123), cervical without hydrocephalus (113), thoracic without hydrocephalus (71) and thoracic with hydrocephalus (52). 465 live births had unspecified SB with hydrocephalus and 5697 had unspecified SB. As for maternal characteristics, 45.6% were single; 32.9% married; 19.3% in stable union; 1.4% legally separated and 0.1% widowed. In 0.7% of cases, this information was not available. In addition, 32 had no formal education, 177 had from 1 to 3 years, 1172 had from 4 to 7 years, 4636 had from 8 to 11 years, 1528 had 12 years or more and in 48 cases the data was blank. Starting prenatal care early and, consequently, folic acid supplementation is essential in preventing SB. Thus, prenatal care was started in the first month of pregnancy in 19.8% of women, in the second in 36.9% and in the third in 19.4%. This data was not available for 442 cases. About the number of prenatal consultations, 32.1% of the women had fewer than 7 prenatal consultations. **Conclusion:** Lumbar SB was the most common in our analysis, despite the significant number of unspecified

SB. Among the maternal factors, live births with SB were more prevalent in single women and women between 8 and 11 years of schooling. Thus, pinpointing a possible association between SB and unplanned pregnancies. Furthermore, 18% of women did not start prenatal care in the first trimester and 32.1% had less than 7 prenatal consultations, that is, ideal prenatal care is still far from being universal in Brazil, which impacts the prevention of neural tube closure defects.

Background: A cerebrovascular accident (CVA), commonly known as a stroke, is a sudden event that disrupts cerebral blood flow, leading to brain cell damage. Strokes are classified as either ischemic or hemorrhagic. In Brazil, strokes are the second leading cause of death, with approximately 100,000 fatalities annually according to the Ministry of Health. In 2016, there were 188,223 hospitalizations for stroke treatment (Margarido, 2021). Given this significant health burden, research on stroke is vital for improving screening and health promotion. **Objective:** To describe the epidemiological profile of the elderly affected by strokes in the state of São Paulo (Brazil) between 2018 and 2023. **Methods:** This is a retrospective, quantitative, and descriptive study, with data obtained from the Hospital Information System (SIH/SUS) available on the DATASUS platform. The study covers the period from January 2018 to December 2023 and includes individuals aged 60 years or older. Descriptive statistics were applied to the study population, considering variables such as year of hospitalization, sex, color/race, hospitalizations by state, age group, and mortality rate. **Results:** Between 2018 and 2023, the Southeast region of Brazil reported 311,396 stroke hospitalizations. São Paulo had the highest incidence with 144,657 admissions (46.45%), followed by Minas Gerais with 97,583 (31.33%), Rio de Janeiro with 58,057 (18.64%), and Espírito Santo with 11,099 (3.56%). Stroke incidence by sex showed 52.18% were male and 47.81% female. In terms of color, white individuals accounted for 129,657 (41.64%) hospitalizations, pardos (multiracial) for 100,875 (32.39%), black individuals for 25,979 (8.34%), those of yellow ethnicity for 6,902 (2.22%), and indigenous people for 73 (0.23%). However, 47,910 (15.39%) did not specify their race, impacting the analysis. Regarding age groups, those aged 60-79 years were most affected: 113,566 (36.47%) were aged 60-69 years and 112,382 (36.02%) were aged 70-79 years. The 80-89 years group had 85,448 (27.44%) hospitalizations. The average mortality rate was 16.83 deaths per 1,000 inhabitants. Rio de Janeiro had the highest mortality rate at 21.66 per 1,000 people, followed by São Paulo at 16.68, Espírito Santo at 15.33, and Minas Gerais at 14.34. **Conclusion:** The results indicate that the incidence of stroke is higher in the state of São Paulo compared to other states in the Southeast region of Brazil. Additionally, the mortality rate is higher in men than in women. Based on color/race, white people have a higher stroke rate compared to other races. In terms of age, two groups (60-69 years and 70-79 years) show similar and higher likelihoods of experiencing a stroke compared to the 80-89 years age group. The mortality rate was considered high according to the data studied. Finally, it is worth noting that this work is a descriptive analysis of data, limiting the discussion about the variables studied.

https://doi.org/10.5327/CBN240672

Epidemiological analysis of the prevalence and mortality of viral meningitis in the southeast region of Brazil

Amábile Cirilo da Silva[1], Samara Brissi Benito da Silva[2], Gabriel Vergolino Eleres[3], Rafaella Ferreira dos Santos[4], Sara Maria Soares Mcgill[5], Hévila Ferreira Gomes Medeiros Braga[6], Danielle de Souza Mometto[7]

Background: Meningitis is defined as inflammation of the tissues surrounding the spinal cord and brain, with bacterial, viral, or aseptic etiologies. The disease is endemic in Brazil and is transmitted through respiratory droplets. Among the known etiologies, viral meningitis is the most common, accounting for approximately 46% of all cases, and showing higher prevalence in the fall, spring, and summer, reflecting the dominance of enterovirus infections such as Coxsackie and Echovirus. To date, there are no studies addressing the prevalence of viral meningitis in southeastern Brazil over the past 10 years, despite it being a significant public health concern. **Objective:** To analyze the epidemiological profile of the prevalence and mortality of viral meningitis in southeastern Brazil from 2013 to 2023. **Methods:** This is a descriptive ecological study of confirmed cases and deaths from viral meningitis in the southeast of Brazil, obtained from the Notifiable Diseases Information System. The study included users of the Unified Health System from January 2013 to May 2023. The following variables were analyzed: age group, deaths, notification region, and state. **Results:** In the period analyzed, the data showed that, in terms of the spatial distribution of the number of cases of viral meningitis, the Southeast region had the highest prevalence and the highest number of deaths among the regions of Brazil, representing 43,055 notified cases (61.8%), with the majority in the population in the aged group of 1 to 4 years, with 11,943 cases (27.7%) and 570 deaths (1.3% of cases) across all age groups. In the Southeast region, São Pulo state stood out with the highest prevalence and deaths, accounting for 37,549 cases (87.2%) and 406 deaths (71.2%). However, as described in the literature, sometimes, because it is a disease with fewer complications and a greater likelihood of progressing to a cure even without intervention, there are many unrecorded cases, especially in areas with difficult geographical access and limited health services coverage. In addition, cases that progress to death may also be underreported when recorded as having an unspecified cause. **Conclusion:** Viral meningitis is prevalent in the Southeast region of Brazil, especially in the state of São Paulo and among preschool aged children. These findings reinforce the need to improve actions to identify and prevent the disease, as well as the importance of including accurate notifications by healthcare. Moreover, it is plausible to make the population aware of the signs and symptoms to ensure that care is sought promptly. These efforts are essential for monitoring the disease´s epidemiological characteristics and implementing effective interventions.

https://doi.org/10.5327/CBN240673

Epidemiological analysis of traumatic brain injury in the Brazilian unified health system, 2012 to 2022

Ana Clara de Lemos Guimarães[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Ana Clara de Lemos Guimarães; Email: anaguimaraes21.1@bahiana.edu.br.

Background: Traumatic brain injury (TBI) is the leading cause of death and disability in adults, primarily affecting men and individuals under 45 years of age. Its high cost to the Brazilian Unified Health System (SUS) and its high incidence and morbidity and mortality rates, coupled with a lack of epidemiological studies, make it urgent to develop demographic analyses to support the planning of interventions. **Objective:** To define the epidemiological profile of TBI hospitalizations in Brazil from January 2012 to December 2022. To determine the temporal trend of hospitalization and annual mortality rates; describe the spatial distribution by region and determine the lethality of TBI. **Methods:** This is an epidemiological, descriptive, retrospective, and quantitative study of TBI hospitalizations in Brazil. Data were obtained from the Hospital Information System (SIH) of the Department of Informatics of the Brazilian Unified Health System (DATASUS). The variables analyzed were: biological sex, age group, geographical region, total cost, and average length of hospital stay. Descriptive statistics were used to analyze the variables, which were presented as raw numbers, hospitalization, mortality, and lethality rates. **Results:** Between 2012 and 2022, there were 1,466,716 TBI-related hospitalizations in Brazil, with 77.31% being men and 22.68% women. The overall lethality of TBI was 7.57%; the total cost was R$2,514,910,263.00, and the average length of hospital stay was 5.9 days. The hospitalization rate showed a decreasing and statistically significant trend (R^2=0.357 β=-0.587 p=0.04). The South region had the highest hospitalization rates. Men had a hospitalization rate 3.53 times higher than women, and individuals aged 80 and over had the highest rates. The mortality rate was higher among men (average of 7.93 per 100,000 inhabitants) compared to women (average of 1.93 per 100,000 inhabitants) and higher in the age group of 80 and over (average of 32.37 per 100,000 inhabitants). Lethality was higher among men (7.9%) compared to women (6.49%), with a lethality ratio of 1.22 (95% CI: 1.20-1.23). Patients aged 80 and over had the highest lethality (19.23%), while the lowest lethality was among those under one year to nine years old. The South region had the lowest lethality rate (5.56%) and the Southeast region the highest (8.47%). **Conclusion:** The data indicate a high prevalence of TBI among men and increasing lethality with age, especially in individuals over 80 years old. There is a decreasing trend in hospitalization rates, but the financial and social impact of TBI remains significant. Regional analysis shows variations in lethality rates, with the Southeast region presenting greater challenges. These results highlight the need for health policies aimed at TBI prevention and improved care for more vulnerable groups, especially men and the elderly.

https://doi.org/10.5327/CBN240674

Epidemiological analysis of traumatic brain injury in the Northern region of Brazil from 2019 to 2023

Background: Traumatic Brain Injury (TBI) is a leading cause of death and disability among young adults, accounting for approximately 2.5 million deaths and 60 million disability cases annually. Patients with TBI may experience cognitive, motor, behavioral, and social functionality impairments. The most common causes include traffic accidents, falls, and assaults. Consequently, TBI is a significant topic of discussion today, as this health issue primarily affects the active age group of the population. **Objective:** To identify the epidemiological profile of reported Traumatic Brain Injury cases in the Northern region of Brazil between 2019 and 2023. **Methods:** An exploratory, descriptive, epidemiological, time-series study was conducted on traumatic brain injury in the Northern region of Brazil between 2019 and 2023. Data were obtained from the Department of Information of the Brazilian Unified Health System (SUS) through the Hospital Information System of SUS, including cases of hospital admissions and deaths due to TBI. The variables studied included hospital admissions, deaths, age group, and gender. The information was tabulated in Microsoft Office Excel® and presented in charts and tables for better analysis. The database used is open for public access without the need for approval from the Research Ethics Committee, and accessible to the public and interested researchers. **Results:** The study identified a total of 41,129 hospitalizations due to TBI in the Northern region between 2019 and 2023, along with 3,367 deaths, this translates to an overall mortality rate of approximately 8.2%. Pará recorded the highest number of hospitalizations (55.5%) and deaths (51.9%). Conversely, Acre registered the fewest deaths, with a total of 89 cases. Additionally, three states showed a reduction in TBI-related deaths over the years: Acre, Amazonas, and Roraima, with decreases of 31.6%, 14%, and 26.5%, respectively. In terms of gender, there was a higher prevalence of males in both hospitalizations (76.5%) and deaths (80.7%). Thus, the mortality rate among men was 8.6%, while for women, it was 6.7%. The age group with the highest number of hospitalizations and deaths was 20 to 29 years, accounting for 21.3% of total hospitalizations and 18.7% of deaths. Moreover, the highest mortality rate was observed in the age group of 80 years or older, at 20.3%, while the lowest was in the 1 to 4 years age group, at 1.08%. **Conclusion:** As evidenced, TBI is a significant cause of hospitalizations and deaths in the Northern region, constituting a serious public health issue. Despite the increase in the number of traumatic brain injury cases in the region, there was a reduction in the number of deaths in three states, indicating the potential for improvement in the current alarming scenario.

Correspondence: Mariana Teixeira Mesquita; Email: maritmesquita@gmail.com.

Background: Zika virus (ZIKV) represents a significant threat to public health due to its correlation with microcephaly in newborns when infecting pregnant women. Therefore, epidemiological studies of this association across diverse populations are crucial for effectively directing public resources and guiding the development of appropriate therapeutic and preventive measures. **Objective:** To identify and analyze the epidemiological profile of Zika virus infections associated with cases of microcephaly in regions of Brazil, from 2015 to 2023. **Methods:** This is an ecological observational epidemiological study with a descriptive quantitative approach, which relied on analyzed data from the Department of Informatics of the Unified Health System (DATASUS). The research was conducted using data from Notification of Suspected Cases of CZS (Congenital Syndrome associated with Zika virus infection) registered from 2015 to 2023. The parameters of "laboratory diagnosis of zika in pregnant women: yes" and "congenital abnormalities detected: microcephaly only, microcephaly with CNS alteration, and microcephaly with other congenital abnormalities" were selected. The variables considered were: year of notification and regions of Brazil. Finally, the collected data were organized and systematized in Microsoft Excel, and analyzed using descriptive statistics. **Results:** The years 2015 and 2016 saw the highest number of notifications of pregnant women diagnosed with Zika in association with newborns with congenital microcephaly, with 541 cases, representing 65.2% of the total. Subsequent years showed a decreasing trend in the association of cases across all regions of Brazil, with 2023 having the lowest frequency of records, with 20 cases (2.4%). The most affected regions were the Northeast with 396 cases (47.7%) and the Southeast with 278 cases (33.5%) in all analyzed years, with the peak of records in the Northeast occurring in 2015, with 189 cases, and in the Southeast occurring in 2016 with 149 cases. The Southern region was the least affected, with 13 cases (1.6%) during the period, followed by the Northern region with 57 cases (6.9%) and the Central-West region with 86 cases (10.4%). Despite significant regional variability, there was a general downward trend in reported cases over the years. **Conclusion:** Following the outbreak of Congenital Syndrome associated with Zika virus infection cases in 2015 - 2016, there was a significant decrease in notifications across all regions of Brazil, which may be related to increased awareness and disease prevention regarding Zika virus infection; development of herd immunity; advancements in epidemiological surveillance and case control; successful vector control measures, among others. Therefore , it is important to highlight the role of epidemiological data analysis in shaping public policies and improving the health condition of affected populations.

https://doi.org/10.5327/CBN240676

Epidemiological and clinical characteristics of patients with Guillain-Barré syndrome in a hospital in the Northeast of Brazil after pandemia: preliminary results

Jesângeli de Sousa Dias[1,2], Leonardo Sousa de Jesus[2], Jessica Abreu de Azevedo Nascimento[2]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.
[2]Secretaria de Saúde do Estado da Bahia, Instituto Couto Maia, Salvador BA, Brazil.

Correspondence: Jesângeli de Sousa Dias; Email: jesangelidias@gmail.com.

Background: The Guillain Barré syndrome (GBS) is the leading cause of flaccid paralysis in the world. In general, an infection precedes the disease in most cases. In Brazil, as in other countries, there was an increase in the number of GBS cases after the introduction of the Zika and Chikungunya viruses. Furthermore, cases associated with COVID-19 have been described and we do not know whether this virus may have led to increased GBS cases in our country. **Objective:** Investigate the influence of the pandemic on the prevalence and clinical-epidemiological characteristics of GBS cases admitted to a hospital in the Northeast of Brazil. **Methods:** This retrospective observational study is based on a review of medical records of individuals consecutively hospitalized from January 1, 2021, to December 31, 2023, with ICD 10 G61.0. We included cases defined according to the Brighton criteria and evaluated at least once by a neurologist. Records with insufficient data were excluded. Data were described as median and interquartile range or absolute and relative frequency as appropriate. **Results:** 33 medical records have been evaluated so far. Most participants came from the capital and metropolitan region (60.6%), 67% were male, and the median age was 28 (IQR: 21.5 - c 45) years. A history of previous infection was present in 60.6% of cases (dengue, 15.1%; diarrhea, 12.1%; respiratory infection with diarrhea, 12.1%; respiratory infection, 9.1%; undefined infection 9,1%). The time after infection and onset of symptoms was 15 (IQR: 7 - 25) days. History of vaccine use was present in 15.1%. All participants had some degree of muscle weakness with reduced or absent reflexes. The most frequent neurological manifestations were ascending muscle weakness (72.7%), mild to moderate sensory symptoms (66.6%), unilateral or bilateral facial paralysis (51.5%), dysautonomia (45.4%), dysphagia (39.4%) and need for mechanical ventilation in 15.1%. The length of stay was 18 (IQR: 10 - 40) days. CSF study showed 2 (IQR:1.25 - 2.0) cells/mm3 and 96 (IQR: 80.25 - 189.25) mg/100mL of proteins. Positive serology for arbovirus was found in 15 participants (IgM Zika, 3; IgM Chikungunya 7; IgM Dengue 5). The SARS-CoV-2 was identified in 3 participants. However, these infectious agents were not screened for in all participants. Twenty-six participants were treated with intravenous immunoglobulin. There were no deaths and at the time of discharge, 45.5% of individuals were confined to a bed or in a wheelchair. **Conclusion:** In our country, it seems that arboviruses continue to be the infectious agents most frequently associated with GBS cases. These results are in line with previous reports. These numbers may be an underestimate as not all participants were tested. We hope that the evaluation of the remaining cases will provide us with additional information. We must be aware that cases of Guillain Barre are expected to increase, following the increase in cases of arboviruses.

[2]Universidade de Pernambuco, Garanhuns PE, Brazil.

Correspondence: Maria Vitória do Nascimento Silva; Email: vitoria.nsilva@upe.br.

Background: Stroke is characterized by sudden neurological deficit with a national incidence of 108 cases per 100,000 persons and a crude mortality rate of 62 cases per 100,000 persons. As the leading cause of global mortality, it is necessary to establish primary prophylactic measures by altering modifiable risk factors and conducting etiological investigations to define secondary prophylaxis, especially after determining the epidemiological profile. **Objective:** To describe the epidemiological profile of patients admitted to an emergency service of the Pernambuco. **Methods:** This observational, descriptive, and cross-sectional study was conducted at the Professor Agamenon Magalhães Regional Hospital, a reference hospital for emergencies in the hinterlands of Pernambuco. The population included cases with a clinical-radiological diagnosis of stroke admitted to the service, and the sample was consecutive. After diagnostic confirmation, patients were clinically evaluated and subjected to the Self- Reported Health Conditions/Situations Questionnaire, TOAST Classification (Trial of ORG 10172 in Acute Stroke Treatment), and the Stroke Prophylactic Measures Questionnaire. **Results:** The sample consisted of 194 participants, of which 92.8% had ischemic stroke and 7.2% had hemorrhagic stroke. The majority (76.8%) were over 60 years old, predominantly male (54.6%) and mixed-race (49.5%). Regarding occupational status, most had previously worked as farmers (46.9%) and were currently retired (71.1%). In terms of education level, most of the sample was uneducated (38.7%). Due to the lack of care services in the region of origin, 35.6% of the patients came from 22 municipalities adjacent to the referral hospital. Concerning comorbidities, 81.4% had a diagnosis of systemic arterial hypertension, 50% of diabetes mellitus, 32.5% had a previous stroke, 10.3% heart failure, 8.2% acute myocardial infarction, 3.6% had a transient ischemic attack, 5.7% had chronic kidney disease, 4.1% malignant neoplasia, and 12.4% were bedridden. Regarding lifestyle habits, smoking and alcohol consumption were noted in 28.4% and 19.6% of patients, respectively. Furthermore, 87.6% were sedentary, and 79.3% did not follow a specific dietary guideline. In terms of prophylactic measures, only 39.7% of patients used some prior screening method for diabetes mellitus, only 30.4% underwent any screening test for dyslipidemia and 10.3% practiced at least 4 hours of physical activity per week. As for the etiology of stroke, about 58% were of indeterminate cause; 16% from large vessels; 10% from small vessels; and 8% cardioembolic. **Conclusion:** There is a need to implement an etiological investigation program for cases admitted to units in the northeastern interior, aiming at promoting secondary prophylaxis. Furthermore, this research advises investing in the control of modifiable risk factors, which are common in the evaluated population.

Epidemiological and clinical profile of patients with Guillain-Barré syndrome at a university hospital in Mato Grosso do sul, from 2018 to 2023

Isabela de Carvalho Florencio[1], Thiago Dias Fernandes[1]

[1]Hospital Universitário Maria Aparecida Pedrossian, Campo Grande MS, Brazil.

Correspondence: Isabela de Carvalho Florencio; Email: isabelacflorencio@hotmail.com.

Background: Guillain-Barré syndrome (GBS) stands as the predominant cause of acute flaccid paralysis on a global scale. It is characterized as an acute or subacute inflammatory polyradiculoneuropathy, resulting in progressive and symmetrical weakness, areflexia, often accompanied by sensory symptoms and autonomic manifestations. GBS is most associated with infections, vaccinations, malignancies, and even trauma. Diagnosis is clinical, but ancillary tests such as cerebrospinal fluid analysis and electromyography are useful for differential diagnosis. Early diagnosis and treatment significantly impact the disease's course, affecting morbidity and mortality. **Objective:** Describe the clinical and epidemiological profile of patients treated with GBS at a tertiary-level public hospital in Campo Grande from 2018 to 2023. **Methods:** Cross-sectional, descriptive study, based on data from medical records of patients with GBS, treated at the University Hospital in the capital of Mato Grosso do Sul, between January 2018 and February 2023. **Results:** During the study period, twenty-four patients were diagnosed with GBS. The mean age was 41.9 years. Most of the patients were male (69.6%). The incidence of cases was higher in summer (43.5%) and at its nadir was in spring (13.0%). Trigger events were identifiable in 68.2% patients, with 33.6% of arboviruses, 20% gastroenteritis, 40% influenza-like syndromes, and 6.3% trauma. The classic form of ascending tetraparesis was observed in 60.9% of patients, while 17.4% had the cervicobrachial pharyngeal form, and 8.7% presented an overlap of the cervicobrachial pharyngeal form and Bickerstaff's encephalitis. Albumin-cytological dissociation of CSF was detected in fourteen patients, with a mean protein value of 113.3 mg/dl. Twenty patients received immunoglobulin treatment, and two patients underwent two treatment cycles. The average hospital stay was 30.2 days, with 26.1% of patients requiring ICU and mechanical ventilation, with an average of 83.2 days in the hospital. The mean duration of hospitalization was 8 days for the classic form and 82 days for the cervicobrachial pharyngeal form, showing a statistically significant difference (p-value 0.004). Clinical complications were observed in 83.3% of patients with the cervicobrachial pharyngeal form compared to 7.1% of the classic form and 33% of other forms. **Conclusion:** The data from this study are in accordance with the literature and contributes to outlining an epidemiological profile of the GBS population in Mato Grosso do Sul.

Background: Stroke is a multifactorial and complex disease that gains significance in the medical field due to its high incidence, mortality, and morbidity rates. In Brazil, Ordinance Nº. 665 was published on April 12, 2012, aiming to establish qualification criteria for establishments as Urgency Care Centers for Stroke Patients, to institute financial incentives and to approve the Stroke Line of Care within the Emergency and Urgency Healthcare Network (RUE) of the Unified Health System (SUS). **Objective:** To analyze the epidemiological and healthcare indicators of the Stroke Line of Care between 2012 and 2021. **Methods:** This is a cross-sectional study. Data from the Mortality Information System (SIM) were used to determine the mortality rate from cerebrovascular diseases. A joinpoint regression model was used to determine the trend in the mortality rate. Data from the National Registry of Healthcare Establishments (CNES) were used to determine the number of establishments qualified as Urgency Care Centers for Stroke Patients. Data from the Hospital Information System (SIH) were used to determine the percentage of patients who underwent thrombolytic treatment. **Results:** The average annual mortality rate from cerebrovascular diseases was 49.08 deaths/100,000 inhabitants in Brazil between 2012 and 2021. It was noticed a decreasing trend in mortality rate (AAPC: -0.68 [-1.03; -0.32]; p: 0.002). This trend was followed by the Northeast (AAPC: -0.52 [-0.99; -0.04]; p: 0.04), Southeast (AAPC: -0.78 [-1.19; -0.37]; p: 0.002) and South (AAPC: -1.27 [-2.03; -0.52]; p: 0.005) regions. The Midwest region, however, presented a stationary trend (AAPC: -0.05 [-0.37; 0.28]; p: 0.75). Only the North region showed an increasing trend (AAPC: 0.97 [0.26; 1.69]; p: 0.008). The North region was also the only one to present a joinpoint, dividing into a first period with an increasing trend between 2012 and 2014 (APC: 3.95 [0.07; 7.98]; p: 0.047) and a second with a stationary trend (APC: 0.14 [-0.37; 0.65]; p: 0.52). 110 Urgency Care Centers for Stroke Patients were identified. Among them, 16 were qualified as Type I, 30 as Type II, and 64 as Type III. 10 Federative Units did not have qualified establishments: Rondônia, Acre, Amazonas, Roraima, Amapá, Tocantins, Piauí, Rio Grande do Norte, Mato Grosso and Goiás. Only 1.14% of stroke cases underwent chemical thrombolysis. No Federative Unit reached the quality target of 20%. The best thrombolysis ratios were in Ceará (8.22%), Distrito Federal (4.46%) and Rio Grande do Sul (2.91%). **Conclusion:** A reduction in cerebrovascular diseases mortality has been observed, however a small proportion of patients treated are subjected to thrombolytic treatment. Despite a decade have passed since the institution of the Stroke Line of Care within the Emergency and Urgency Healthcare Network, there is still a deficiency in the distribution of Urgency Care Centers for Stroke Patients in Brazil.

[4]Universidade de Franca, Franca SP, Brazil.
[5]Instituto Projete Ciências.

Correspondence: Henrique Kallás Ribeiro do Valle; Email: henrique.krv@icloud.com.

Background: Meningitis is defined as the inflammation of the membranes surrounding the brain and the spinal cord. Its etiologies that demand the most attention are: viral (VM) and bacterial (BM). **Objective:** The study was carried out with the objectives of identifying data on hospitalizations and deaths due to BM and VM at national and regional levels, and evaluating the respective incidence, mortality and lethality rates. **Methods:** Quantitative and retrospective ecological study, based on public data collected from the System of Notifiable Diseases Information (SINAN), regarding hospitalizations and deaths due to BM and VM occurring in Brazil and the federative regions in the period from 2018 to 2023, available in the DATASUS system. The absolute and relative values were recorded in an electronic spreadsheet and the statistical significance between the means was evaluated based on the p value <0.05. **Results:** In the period from 2018 to 2023 in Brazil, The number of hospitalizations due to BM (21,190) was significantly higher (p=0.002) than those due to VM (12,768). Similarly, the number of deaths due to BM (2,052) was significantly higher (p=0.0002) than those due to VM (481). This quantitative superiority of BM in relation to VM is reflected

at national and regional levels in the rates of: incidence (BM - 10.43 / VM - 6.29), mortality (BM - 1.01 / VM - 6.29) and fatality (BM - 0.10 / VM - 0.04). There was no significant difference (p≥0.05) between the number of cases in men (57%) in relation to women (43%), regarding hospitalizations or deaths. Data on hospitalizations and deaths due to BM or VM reported in the Southeast region were significantly higher (p<0.05) in relation to other regions, followed initially by the Northeast or South regions, which presented values without significant differences between them, but significantly higher in relation to the North or Central-West regions, which presented statistically equal numbers of notifications. However, there is a variation in classification between regions in relation to the highest and lowest values relating to incidence (IR), mortality (MR) or fatality (FR) rates. The South presented the highest IR for both BM (14.46) and VM (8.66); and the Northeast, the lowest IR for BM (8.41); and the North, for VM (4.26). While the highest MR of BM (1.27) and VM (0.35) were also in the South, and the lowest in the Central-West (0.72 and 0.17). The Southeast, North and Northeast regions had the highest FR per BM (0.10) and the Central-West, the lowest (0.08). While in the North there was the highest FR per VM (0.05) and in the Northeast, the lowest (0.03). **Conclusion:** The orders of magnitude of occurrence of BM and VM associated with the respective risks to survival, both in men and women, highlight a situation of health problems and suggest the need to implement preventive public policies in all federative regions of the country, with greater emphasis on bacterial meningitis.

Epidemiological aspects of hospital admissions for Alzheimer's in Brazil from 2015 to 2019

Ana Carolina Ribeiro de Araujo e Araujo[1], Aeriberto Carlos Lindoso de Souza[1], Consuelo Penha Castro Marques[1], José Carlos Gomes Patriota Neto[1], Tassya Jordana Coqueiro Batalha[1]

[1]Universidade Federal do Maranhão, Pinheiro MA, Brazil.

Correspondence: Ana Carolina Ribeiro de Araujo e Araujo; Email: anacarolinaraa@hotmail.com.

Background: Alzheimer's disease is a neurodegenerative dementia disease resulting from multiple pathophysiological factors, implying a progressive decline in the patient's logical and behavioral capabilities resulting from the manipulation of cholinergic neurons, causing fundamental losses that include behavioral and cognitive impairment, that is, the memory, language, the ability to understand and logical reasoning. It very commonly affects elderly people, resulting in several serious health complications, causing the entire society and the health system to be directly affected. **Objective:** To analyze the epidemiological profile of Alzheimer's disease hospitalizations in Brazil. **Methods:** An exploratory, descriptive, epidemiological, time series study was carried out from 2015 to 2019, with secondary data from DATASUS - Ministry of Health, Brazil. **Results:** During the period under study, there were n=7833 hospitalizations due to Alzheimer's in Brazil, from 2015 to 2019, with a highest peak in 2015, a lower number of hospitalizations in 2016 and an oscillating trend until 2019 where there was a large increase, making an average = 1566 .6 (±1823.93) and Coefficient of Variation (CV)=116.43%. The Southeast had the highest percentage of hospitalizations with 59% and the South 22%. Females accounted for 65% of hospitalizations, the most prevalent age group was 70 to 80 years old and + with 87%, white people were more frequent with 46.68%. The total amount spent was R$ 13,459,451.43, the Southeast was responsible for 77% of this amount spent. The average stay was 22.6 days. The number of deaths (n=1461) and the mortality rate of 18.65. **Conclusion:** Given this, considering the increase in the number of hospitalizations and deaths at a national level, corroborated by the prospect of an increase in the number of elderly people in the coming years, it is of fundamental importance that municipal, state and federal health managers turn their attention to the adoption of public policies that cover this population, guaranteeing, in addition to greater longevity, a better quality of life in terms of physical, mental and psychological aspects.

https://doi.org/10.5327/CBN240682

Epidemiological aspects of patients affected by stroke in the Southeast region between Jan/2018 to Jan/2024

Background: The definition of stroke can be described as the presence of a neurological deficit of focal vascular etiology and abrupt onset, with a variable clinical picture. Stroke has a prominent role in the group due to its high incidence, given its position as the second leading cause of death in the world and the estimated increase in cases due to the advancement of population life expectancy. **Objective:** This study aims to analyze and describe the epidemiological profile of stroke in Southeast Brazil between 2018 and 2024. **Methods:** This is a cross-sectional, descriptive study with a quantitative approach, obtained by extracting data from DATASUS on the states of the Southeast region of Brazil between January 2018 and January 2024. **Results:** The study revealed a total of 443,529 hospitalizations for stroke in the Southeast region between 2018 and 2024, as well as a total of 67,425 deaths (15.2%). Minas Gerais recorded the highest number of hospitalizations, considering the total number of inhabitants, with a total of 137,087, while second place (Rio de Janeiro) recorded 82,808 hospitalizations. The state with the lowest record was Espírito Santo, which had 15,222 hospitalizations. As for the number of deaths, Rio de Janeiro recorded the highest number (16,305), followed by Minas Gerais (18,017) and São Paulo (30,976). In terms of gender, the majority of hospitalizations for strokes were of male victims (52.5%). Males also accounted for 51.2% of deaths in the period analyzed, with the highest mortality rate of all the states in the region. It can be seen that the number of hospitalizations increases sharply as the population ages. It can also be seen that strokes occur more frequently between the ages of 60 and 79 (52.5%). Furthermore, this disease is more lethal in the elderly aged 80 and over, given the higher mortality rate in this age group (29.3%). When color/race is analyzed, it is possible to observe a prevalence of cases in the white population in the Southeast region, which registered 176,464 cases of hospitalizations. The state of São Paulo led the way, both in terms of hospitalizations, which alone accounted for 114,703 cases (25.8%), and in terms of the number of deaths (16,982), which represents 25% of total deaths. The yellow population comes next with 150,995 hospitalizations and 22,326 deaths in all regions. It is important to note that of the total hospitalizations, 67,366 were not recorded according to color/ethnicity. **Conclusion:** As a result, it was concluded that, as the disease is one of the main causes of death in Brazil and its epidemiological profile affects a more debilitated population, characterized by elderly individuals, it is of the utmost importance to disseminate knowledge about stroke, with a view to prevention and early identification of cases through the development of preventive and structural strategies that can contribute to reducing the frequency of patients affected by the disease.

Correspondence: Lia Mayra Miranda Santos; Email: lia13mayra@gmail.com.

Background: Encephalitis is defined as inflammation in the tissues of the nervous system and one of the most common etiologies is due to viral infectious agents. Bringing together a varied series of conditions, it most often presents with direct involvement of the brain parenchyma demonstrated by a lowered level of consciousness, seizures and/or focal neurological deficits. Being potentially fatal diseases, with associated sequelae and variable transmissibility, epidemiological understanding is of vital importance for effective management and reducing the impact on public health. **Objective:** To analyze the epidemiological profile of patients affected by viral encephalitis in the Southeast region between 2019 and 2023. **Methods:** This is a descriptive, cross-sectional epidemiological study that analyzed the epidemiological profile of patients affected by viral encephalitis in the Southeast Region of Brazil between 2019 and 2023. Data on hospitalizations, deaths and mortality rates were provided by the Department of Informatics of the Unified Health System (DATASUS) and were analyzed according to the variables: age group, gender, year and color/race. **Results:** There were 2,530 cases of people hospitalized for viral encephalitis in the Southeast between 2019 and 2023 and 145 deaths, resulting in a mortality rate of 0.03 per 100,000 inhabitants. Of the hospitalizations, 27.9% were children aged 0 to 4, with 8.4 deaths per 1,000 hospitalizations in this age group in the Southeast; however, there were more deaths in adults, with a peak in the 30 to 39 age group (22). With regard to the sex of the patients, there was a predominance of males in both the total number of hospitalizations and the total number of deaths. This trend was maintained in all states, with the exception of São Paulo, which had more female deaths in the period analyzed (41). As for the race/color variable, there was a higher number of hospitalizations and deaths among individuals identified as white and brown, totaling 76.2% of all hospitalizations and 73.8% of deaths. In relation to the number of total hospitalization records, the year 2019 showed the highest rate of hospitalizations in the years analyzed (586), however the highest number of deaths was seen in the year 2023 with 34 deaths. **Conclusion:** In this way, it can be inferred that viral encephalitis has low mortality associated with the number of cases, it is also understood the epidemiological profile of involvement that refers, above all, to hospitalizations for white and brown individuals, and males, it is noteworthy, however, the rate of hospitalizations for the child population, which denotes the need to evaluate this population in order to be able to screen for this condition.

Epidemiological aspects of pediatric patients affected by viral meningitis in the Southeast region between 2019 and 2023

Lia Mayra Miranda Santos[1], Lorena Carvalho Plens[2], Aryane Agatha Rocha da Silva[3], Cleiton da Silva Santos[3], Victoria Verissimo Santos[4]

[1]Universidade Anhembi Morumbi, São Paulo SP, Brazil.
[2]Universidade Federal do Paraná, Toledo PR, Brazil.
[3]Universidade Estadual do Sudoeste da Bahia, Vitória da Conquista BA, Brazil.
[4]Universidade do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Lia Mayra Miranda Santos; Email: lia13mayra@gmail.com.

Background: Meningitis is an infection caused by viruses, fungi, or bacteria, affecting the meninges region. The majority of meningitis infections are viral, with enterovirus being the most common in the pediatric population. Children usually present with fever, vomiting, anorexia, respiratory symptoms, and conditions similar to viral infections, with younger children often having a highly nonspecific presentation. Therefore, understanding the epidemiological profile of different regions in Brazil helps establish a more precise clinical approach in medical practice. **Objective:** Increase knowledge about the epidemiological profile of pediatric patients affected by viral meningitis in the Southeast region of Brazil between 2019 to 2023. **Methods:** This is a cross-sectional, descriptive study with a quantitative approach based on epidemiological data provided by the Ministry of Health in the "TABNET" data tabulation tool of the Department of Informatics of the Unified Health System (DATASUS). The data was collected from the SUS Hospital Information System (SIH/SUS), by place of hospitalization, in which viral meningitis was selected from the ICD-10 list of morbidities. For the collection, filters were applied for the period from January 2019 to December 2023, the age ranges up to 19 years and the location was restricted to the southeast region, which covers the states of Minas Gerais, Espírito Santo, Rio de Janeiro and São Paulo. In addition, the division by color/race was also inserted. **Results:** The study revealed a total of 2,723 hospitalizations for viral meningitis in the Southeast region between 2019 and 2023, as well as a total of 38 deaths among individuals up to the age of 19. Regarding the number of total hospitalization records, the year 2019 showed the highest rate of hospitalizations, reaching 31.3% of the 2723 recorded in the database during the period analyzed. Among the states, hospitalizations in São Paulo reached 71.9% of the total number of hospitalizations recorded. When comparing the records according to color/race and taking out the individuals not classified as black, white, brown, or yellow (2,304), we observed a greater number of records for white people, totaling 53.3% of the sample. There was a predominance of males among those hospitalized for viral meningitis in the total number of records both in the Southeast and in each state separately. The most affected age group was children under the age of 1, with a total of 922 records over the period analyzed. **Conclusion:** Pediatric meningitis is a public health concern due to its potentially serious nature. Epidemiological surveillance is crucial in contributing to accurate diagnoses and effective interventions, intending to minimize the sequelae and fatal outcomes associated with the disease. Thus, by producing up-to-date scientific information, medical practice can be based on the best scientific evidence available, and, as a result, public policies can become increasingly efficient.

Background: Microcephaly is a congenital disease characterized by a head circumference less than two standard deviations from the mean for the gestational age and sex of the newborn. In severe cases, the head circumference is less than three standard deviations. Children with microcephaly may experience delays in neurodevelopment and sensory deficits in multiple systems, such as vision and hearing, depending on the severity of the condition. The causes of this condition are multifactorial, it has several causes, from genetic to infectious, such as Zika virus, STORCH, malnutrition, herpes, toxoplasmosis, cytomegalovirus, rubella, among others. Between 2025 and 2017, Brazil faced a Zika vírus epidemic, which resulted in a significant increase in microcephaly cases, followed by a sharp drop. Currently, little is discussed about microcephaly, which motivated this study. **Objective:** This work aims to provide a brief epidemiological analysis of microcephaly in Brazil from 2015 to 2023. **Methods:** This is a descriptive epidemiological study based on secondary data analysis. Epidemiological data obtained from the Brazilian Ministry of Health and DATASUS were used. The analysis covered the period from 2015 to 2023, focusing on the incidence of reported microcephaly cases. The data was organized and analyzed to identify trends and variations over the years. **Results:** Assessment of the incidence of microcephaly during the study period revealed an epidemic in 2015 (4.135 cases), with an increase of 107.69% in 2016 (8.588 cases), followed by a decrease of 69.04% in 2017 (2.658 cases). The downward trend continued in 2018 (1.733 cases, down 34.80%), 2019 (1.514 cases, down 12.63%), 2020 (1.029 cases, down 32.03%), 2021 (810 cases, drop of 21.28%) and 2022 (749 cases, drop of 7.53%). However, in 2023, there was an increase of 38.18% (1.035 cases). **Conclusion:** Data analysis indicates a strong reduction in cases of microcephaly after the Zika epidemic (2015-2016), but points to a new increase in 2023 with no apparent cause. This recent increase raises several questions: could it be due to the relaxation of prevention and control measures? Could it be associated with the recent Dengue and Covid-19 epidemics, with diverted attention from microcephaly? Could there be flaws in data collection and tracking methods? Or could it be a new pathology or condition that is still unknown? We conclude that it is necessary to turn attention to microcephaly and investigate what led to the recent increase in cases.

Epidemiological characterization of polio vaccination in Brazil and in the state of São Paulo during the 21st century

Helena Rubini Nogueira[1], Helena Rubini Nogueira[1], Luma Falcon Maran[1], Bianca Stephani Ovando Pereira[1], Breno Nascimento Puertas[1], Giulianna Luzia Pereira[1], Geovanna Dhi Genaro[1], João Victor Salas Salles[1], Patrick Cristian Lima Orihuela[1], Lucas Valadão Ferreira de Lira[1]

[1]Universidade Municipal de São Caetano do Sul, São Caetano SP, Brazil.

Correspondence: Helena Rubini Nogueira; Email: helena.rnogueira@live.com.

Background: Poliomyelitis is an incurable viral infection that mainly affects children, with the last recorded case in Brazil being in 1989. Etiopathogenically, the virus replication leads to the damage of the neuronal cells and consequent impairment of the stimuli production responsible for muscle contraction, resulting in paralysis. The diagnosis involves clinical and laboratory investigation and the treatment is mainly to relieve the symptoms. In view of this, the eradication strategy was centered on mass vaccination campaigns, but as this coverage has decreased, the pathology has re-established itself as a global threat. **Objective:** To characterize polio vaccination in the 21st century in the Brazilian context and, more specifically, in the state of São Paulo. **Methods:** Descriptive analysis based on data obtained from DATASUS using the following variables: Vaccination Coverage (Poliomyelitis; Poliomyelitis 4 years); Brazilian Regions; Macro-regions of the state of São Paulo; Period (2001 to 2022). **Results:** Nationally, vaccination coverage rates showed variations from 2010 onwards, previously remaining above 100%. This reduction intensified from 2014 (maximum value 98.29%), with a second worsening in 2020 (average 75.01%). It should be noted that, since 2010, the South, followed by the Midwest, have had the highest vaccination rates, with 41.6% and 33.3% of the total, respectively. In comparison, this coverage fell by 22.22% over the century. When analyzing booster vaccination at the age of 4, there was a drop from 2019 (68.45%) to 2021 (54.61%), with a further increase in 2022 (67.56%). In this section, the South and Midwest once again stood out, with the highest average values. Within the 17 Regional Health Care Networks (RRAS) in the state of São Paulo, it can be seen that RRAS-6 (corresponding to the municipality of São Paulo) showed the lowest total percentage (88.71%) of coverage between 2000 and 2022, while RRAS-12 (which includes Santa Fé do Sul, Jales, Fernandópolis, Votuporanga, São José do Rio Preto, José Bonifácio, Catanduva, Lagos do DRS II, Central DRS II, Consórcios DRS II) showed the highest (100.63%). As for booster vaccination in São Paulo's health macro-regions, RRAS-6 and RRAS-12 showed the best results (averages between 81.83% and 91.31%), while the worst were recorded in RRAS-7 (Baixada Santista and Vale da Ribeira) and RRAS-3 (Franco da Rocha), with 59.12% and 60.91% respectively. **Conclusion:** There has been a sharp drop in vaccination coverage against Polio since 2014 at a national level, as well as in the state of São Paulo, illustrated by the decrease registered mainly in the regional health care network that includes the largest municipality in the country (São Paulo). The importance of vaccination to prevent new cases of the disease, which is considered incurable and highly infectious, is highlighted.

Epidemiological disparities in hospitalizations for multiple sclerosis in the face of the COVID-19 pandemic

Giulianna Luzia Pereira[1], Helena Rubini Nogueira[1], Lucas Valadão Ferreira de Lira[1], Cássio Marques Ribeiro[1], João Victor Salas Salles[1], Patrick Cristian Lima Orihuela[1], Geovanna Dhi Genaro[1], Bianca Stephani Ovando Pereira[1], Breno Nascimento Puertas[1], Luma Falcon Maran[1]

[1]Universidade Municipal de São Caetano do Sul, São Caetano do Sul SP, Brazil.

Correspondence: Giulianna Luzia Pereira; Email: giuliannaluzia2013@gmail.com.

Background: Multiple sclerosis (MS) is an autoimmune disease that affects 2.3 million people worldwide and around 40,000 Brazilians. Its pathogenesis remains unknown, but there is a correlation between genetic susceptibility and environmental agents, such as lack of vitamin D, time of birth, tobacco use and exposure to the Epstein-Barr virus. The diagnosis of the disease is complex because no test or biomarker is specific. It consists of 2 symptomatic episodes lasting more than 24 hours, at least 1 month apart (different time and place). Its treatment consists of drug therapy (mainly with immunomodulators) and non-drug therapy (physiotherapy, physical exercise and psychotherapy). In addition, the advent of the COVID-19 pandemic has posed challenges for MS care, especially in terms of treatment and use of the vaccine, as well as access to health services, factors directly related to the prognosis of the condition. Few studies have managed to make direct correlations between MS and COVID-19 infection. **Objective:** To identify disparities in hospitalizations for multiple sclerosis before, during and after the COVID-19 pandemic according to epidemiological factors. **Methods:** Descriptive analysis based on data obtained from DATASUS using the following variables: ICD 10 morbidity list (multiple sclerosis); Age group; Brazilian regions; Sex; Hospitalizations; Death; Mortality rate; Period (Jan/2018 to Dec/2023). **Results:** There was a reduction in the number of hospitalizations for MS during the pandemic of approximately 1.5%, with an increase in the post-pandemic period of 11%. In addition, it was found that adults aged between 20 and 59 were the group of the population that suffered the most hospitalizations for the condition (n = 28.708; 88%), in contrast to 1.788 children (5.5%) and 1.993 elderly people (6.5%). More specifically regarding to the Brazilian regions, there was no significant variation in the data as a result of the pandemic, with the North remaining the place with the lowest number of hospitalizations recorded (n = 453; 1.4%) and the Southeast the highest (n=24,045; 73.9%), whose female population accounted for 69% of hospitalizations. Considering the number of deaths from MS, there was an increase until 2019 (n=51), led by the Southeast Region (50%). However, the regions showed a drop in this pattern during the pandemic (n=19 in 2020; n=26 in 2021), and a subsequent increase after its end: 2022 (n=34) and 2023 (n=33). In general, there was a reduction in the mortality rate during the pandemic period in all regions, except for the North (2019: 5.88 → 2020: 6.06), with the Southeast having the lowest rate (2020: 0.28 and 2021: 0.15). **Conclusion:** A decrease in the number of hospitalizations, deaths and mortality rates was observed in the vast majority of Brazilian regions during the COVID-19 pandemic, with the adult and female population suffering the most hospitalizations.

Epidemiological factors implicated in Parkinson's disease: a preliminary study of patients from an outpatient clinic with a standardized routine questionnaire

Tatiane Thaís Santos Silva[1], Sophia Keiko Inuzuka[1], Júlio César Iaia[1], Maria Fernanda de Abreu Rodrigues[1], Rhanice Soares Huguenin[1], Iuri Sena Melo[1], Marcos Vinicius Souza Do Nascimento Júnior[1], Roberto Pereira Santos[1], Ana Lucia Zuma de Rosso[1], Rita de Cássia Leite Fernandes[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Tatiane Thaís Santos Silva; Email: tatianethaisufrj@gmail.com.

Background: Parkinson's disease (PD) is a progressive neurodegenerative disease resulting from degeneration of dopaminergic neurons in substantia nigra. Although the exact cause of PD is not yet completely understood, it is fostered by advanced age and the interaction of a variety of environmental factors and genetic factors. **Objective:** To develop a standardized epidemiological questionnaire, quick to apply and easy to understand for patients, to be used in routine neurological consultations to assess socio-environmental factors described as predisposing to the development of PD. **Methods:** Cross-sectional study with patients with a >2y PD diagnosis attending the Movement Disorders outpatient clinic of a universitary hospital who agreed to participate. We developed a structured questionnaire with 19 items that covered medical history, environmental exposures, and lifestyle habits before PD diagnosis. The questionnaire was applied by one of the researchers immediately before the scheduled neurological consultation, noting its execution time and ease of understanding by the patients.The Hoehn & Yahr scale defined the stage of the disease. **Results:** We analyzed 22 patients (77.3% male), with a mean age of 70.1 + 8.2 y (range 51-91y) and an average diagnosis time of 10.1+5.9y. Most participants were white (73%), were in H&Y phase II-III (78.6%) and had <8 years of formal education (59.1%). The questionnaire proved to be relatively easy to understand and quick to complete, taking an average time of 17 min (range 10' to 22'). In 31.8% there was a family history of PD. In 45.5% there was a history of depression, 36.4% had an anxiety disorder and 54.5% referred REM sleep behavior disorder. Furthermore, 36.4% had chronic constipation and 22.7% complained about hyposmia. Only 18.2% reported lifetime pesticide exposure, while 22.7% had a history of traumatic brain injury. Regarding medication use, 13.6% used calcium channel blockers and/or beta-blockers. Behaviorally, 27.3% did not engage in physical activity, but 59.1% reported sun exposure >3 days/week. 50% of parkinsonians denied ever smoking. The average caffeine consumption was 130.7±110.2ml/day. **Conclusion:** The questionnaire developed in this work proved to be practical and should be incorporated into the care of parkinsonians in our hospital. Due to the limited size of the research sample so far, we found some discrepant data in relation to the literature, such as the low rate of pesticides exposure, depression and hyposmia. The importance of epidemiological factors and lifestyle habits for the development and progression of PD has been increasingly emphasized in recent global studies. In routine neurological consultations, however, this search is rarely carried out due to the lack of a quick standardized assessment instrument. In this way, we hope to contribute to future research by enabling the collection of large-scale behavioral, medical and environmental data from our patients.

Epidemiological overview of migraine hospitalizations in Brazil: profile of hospitalized individuals and costs

Matheus Wendell de Almeida Pereira[1], Maria Alice Pereira Junqueira de Oliveira[1], Raissa Jaquelline dos Santos Dias[1], Éricka Pessôa de Azevedo[1], Gabriel da Conceição Veiga[1], Carla Caciana Leocadio Toledo[1], Luísa Lisbôa Machado[1], Camilla de Morais Lavadores[1]

[1]Universidade Federal do Rio de Janeiro, Macaé RJ, Brazil.

Correspondence: Matheus Wendell de Almeida Pereira; Email: mwap1313@gmail.com.

Background: Migraine stands as a pervasive condition worldwide, exerting a profound influence on individuals' quality of life and productivity. Despite its implications, the disorder remains neglected by both patients and healthcare providers. Therefore, understanding the current epidemiological situation regarding this issue is crucial for healthcare services. **Objective:** This study aims to conduct a quantitative analysis of hospitalizations in public healthcare institutions from January 2014 to January 2024, specifically focusing on cases attributed to migraine and other cephalic pain syndromes. The objective is to compare these findings across Brazil's five distinct regions, examining variables such as gender, ethnicity, age demographics, and the average cost of hospitalization. **Methods:** Using observational and cross-sectional approaches, this study utilizes data from Sistema de Informações Hospitalares do SUS (SIH-SUS) via DATASUS. Variables include hospitalizations for migraines and cephalic pain syndromes categorized by region, gender, ethnicity, age groups, and average costs. Data collection occurred from March 18 to 23, 2024. **Results:** During the specified period, Brazil documented 97,156 hospitalizations attributable to migraines and other cephalic pain syndromes, exhibiting a general inclination towards escalation over the years, albeit with declines observed in 2020 and 2021. The Southeast region registered the highest cumulative cases in the period, comprising 32.5% of the total, followed by the Northeast and South with 29.2% and 25.9%, respectively. Regarding gender distribution, females comprised 65.8% of hospitalizations, while males accounted for 34.1%. In terms of ethnicity, Caucasian individuals predominated, constituting 39.64% of cases, followed by "pardo" individuals (multiracial Brazilians), representing 39.62%. Notably, 15.4% of hospitalizations lacked ethnicity information. Moreover, the majority of hospitalizations occurred in individuals aged between 30 and 39 years, accounting for 18.5% of the total, followed by the age group of 20 to 29 years, accounting for 17.8%. It is pertinent to highlight that the average hospitalization cost surged from R$327.10 in January 2014 to R$673.80 in January 2024, peaking at a maximum of R$1,039.24 in the Northeast. **Conclusion:** It is noted that 15.4% of cases lacked information regarding the ethnicity of patients, thus compromising the accurate understanding of the individuals' profile. This deficiency hampers the formulation and execution of public health interventions aimed at preventing complications associated with the condition and ensuring the appropriate treatment of migraine. Furthermore, the two most affected groups represent a segment of the population with significant economic engagement. This underscores the need for effective disorder management, that could help mitigate complications and decrease the frequency cost of hospitalization cases.

Background: Encephalitis is characterized by inflammation of the brain parenchyma due to an acute infection or a post-infectious immune reaction and is associated with altered brain function. Clinical manifestations include fever, headache, focal neurological signs, altered consciousness, and seizures. In 2018, the hospital admission rate for viral encephalitis in Brazil was approximately 1 per 100,000 inhabitants. Therefore, this study aims to provide

an updated epidemiological overview of the condition. **Objective:** To analyze the profile of hospital admissions through the SUS for viral encephalitis in Brazil over the past 5 years. **Methods:** This is an ecological, cross-sectional, and descriptive study using secondary data available from the Hospital Information System of the Unified Health System (SIH/SUS) from 2019 to 2023. The variables analyzed were: demographic region, hospital admissions, sex, age group, and mortality rate. Data were collected and analyzed in May 2024 using descriptive statistics. **Results:** A total of 9,816 hospital admissions for viral encephalitis were recorded in Brazil over the past five years, with the highest number of admissions in the Northeast region. In the first year analyzed, there were 2,436 hospitalizations for viral encephalitis. A 32.4% decrease in the number of hospitalizations was observed from 2019 to 2021. In 2022, there was a new increase, which remained constant until 2023, reaching 2,067 cases. The highest number of admissions was among males (53.5%) and in the age group of 1 to 9 years (30.1%). The highest mortality rate was in 2020 at 6.28%, but in subsequent years, it showed a downward trend despite the increase in the number of hospitalizations. **Conclusion:** There has been an overall increase in the total number of hospital admissions for encephalitis from 2019 to 2023. However, it is important to consider that the COVID-19 pandemic likely influenced the significant reduction in the number of admissions between 2020 and 2021. In this context, the current challenge for the country is to reduce the number of hospital admissions through the SUS, as although the mortality rate is decreasing, the increase in hospitalizations indicates that this condition remains a public health challenge in Brazil.

https://doi.org/10.5327/CBN240691

Epidemiological profile and comorbidities of patients with Parkinson's disease at an university hospital

Ligia Aranha Puig Maldonado[1], Denise Hack Nicaretta[1], Maria Aparecida de Assis Patroclo[2]

[1]Universidade Federal do Estado do Rio de Janeiro, Escola de Medicina e Cirurgia, Hospital Universitário Gaffrée e Guinle, Rio de Janeiro RJ, Brazil.
[2]Universidade Federal do Estado do Rio de Janeiro, Instituto de Saúde Coletiva, Rio de Janeiro RJ, Brazil.

Correspondence: Denise Hack Nicaretta; Email: denisehn@terra.com.br.

Background: Parkinson's disease (PD) is a neurodegenerative disorder with onset prior to age 60 years, with unclear causes but linked to genetics, environment and aging. Risk factors include male gender, age over 80, pesticide exposure, head trauma, and genetics. It affects over 8.5 million people globally aged over 65, with an estimated 200,000 in Brazil and 7,121 in Rio de Janeiro. PD's prevalence is rising and expected to double by 2040 due to aging populations. **Objective:** To analyze the epidemiological profile and comorbidities in PD patients from the Parkinson's Disease Outpatient Clinic of a University Hospital in Rio de Janeiro city, over a five-year period from 2017 to 2022. The present study is justified due to the high prevalence of PD in the global population, and due to the many aspects to be elucidated both in its pathophysiology and in relation to epidemiology, risk factors, and associated comorbidities. **Methods:** Retrospective cross-sectional observational study. Target population: Adults diagnosed with PD according to the Movement Disorders Society (MDS) criteria from 2015, enrolled in the Parkinson's Disease Outpatient Clinic at a university hospital in Rio de Janeiro, from 2017 to 2022. Data were collected from patient records and self-declared. The project was submitted and approved by the Institutional Review Board for Human Research Ethics, and informed consent was obtained from all participants via telephone. **Results:** 53 patients met the criteria, agreed and gave consent. Among them, 20 (37.7%) were female, and 33 (62.2%) were male. The average age at diagnosis was 57.8 years, 28 (52.8%) identified as white, and a total of 47.9% identified as Black (Black + Mixed race), despite the majority of the population in Rio de Janeiro being black/mixed race. 49.2% had up to elementary education, and 51.8% had higher education levels. 71.6% (38 participants) did not have a history of smoking. 30 (56.6%) had systemic arterial hypertension; 14 (26.4%) had Type II Diabetes Mellitus; and 11 (20.7%) had other cardiovascular diseases. 23 (43.3%) patients had depression/depressed mood; 15 (28.3%) reported anxious mood; and 19 (35.8%) had other disorders. 28 (52.8%) patients reported insomnia; 22 (41.5%) had Rapid Eye Movement Sleep Behavior Disorder. 6 (11.3%) patients had a history of neoplasias. **Conclusion:** White males predominated, with an average age at diagnosis of 57.8 years. Comorbidities like cardiovascular diseases and depression were prevalent. The study suggests the need for standardized data collection and ongoing research to better understand and manage PD in Rio de Janeiro, especially with aging populations.

Epidemiological profile and impact of hospitalizations for complicated migraine in Brazil (2019-2023)

Monyque Pinheiro Charchar[1], Marcos Lude da Silva Ferreira[2], Lívia Vitória Costa Dias[1], Alec Peixoto Rabelo[2], Edson Luis de Barros Siqueira[2], Luiz Carlos Figueiredo Filho[2], Luan Nascimento Pereira de Amorim[2]

[1]Centro Universitário do Pará, Belém PA, Brazil.
[2]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Monyque Pinheiro Charchar; Email: mcharchar10@gmail.com.

Background: Most migraines are adequately treated on an outpatient basis. However, there is a form, known as migraine with aura, which involves more severe or prolonged symptoms, such as persistent auras and neurological symptoms, requiring more specific and immediate medical interventions. **Methods:** Through quantitative and temporal analysis, a study was conducted on data available in the Public Health Event Records (RESP) regarding the frequency of notification of complicated migraine treatment among the Brazilian Federal Units (UF), and variables such as type of hospitalization, death rate, mortality rate, average value, and annual average length of stay. Secondary information was obtained digitally using data tabulation tools TABNET and TABWIN, provided by the Brazilian Unified Health System Information System (SIH/SUS) and made available by the Department of Informatics of the Unified Health System (DATASUS). **Results:** Between 2019 and 2023, 38,908 hospital admission authorizations (AIH) were approved, with a peak in 2019. Additionally, 31.1% were recorded in the Southeast region, with São Paulo having the highest number of AIH (7,313). Pará (1,281), Maranhão (4,186), Paraná (6,185), and Goiás (2,343) also stood out in their regions. Urgent hospitalizations predominated in all states except Goiás, totaling 35,773, while elective admissions amounted to 3,133, all of medium complexity. During this period, the total death rate was 125 cases, with 24% occurring in 2019 and 35.2% in the Northeast region, mainly in Bahia. However, the highest mortality rates were observed in the North region, reaching 0.83 with a peak in 2021, especially in Amazonas (2.65), highlighting 2020 (7.69). The average expenditure was 312.66 Brazilian reais, with higher spending in 2023 (336.89), with the highest rates in the South region, mainly in Paraná (466.32). The average annual length of stay in all regions was 3.4 days, with the highest average in the Northeast (4.1), led by Sergipe (7.6). **Conclusion:** Between 2019 and 2023, 38,908 hospitalizations for complicated migraines were recorded in Brazil, peaking in 2019. The Southeast region had the highest number of hospitalizations, especially São Paulo. Most admissions were urgent, with higher mortality rates in the North, especially in Amazonas. Average costs increased, with the highest spending in Paraná. The average hospital stay was 3.4 days, higher in the Northeast, led by Sergipe. These data emphasize the need for regional public policies to optimize resources, reduce mortality and costs, and improve the treatment of complicated migraines

https://doi.org/10.5327/CBN240693

Epidemiological profile and mortality of hospitalizations for epilepsy in the state of Pará from 2014 to 2023

Fernando Gabriel dos Santos Santiago[1], Danusa Neves Somensi[1], Mariangela Moreno Domingues[1], Emanuel de Jesus Soares de Sousa[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Fernando Gabriel dos Santos Santiago; Email: fernando_gsantiago@outlook.com.

Background: Epilepsy is defined as a predisposition to the development of paroxysmal events characterized by behavioral, sensory, psychic, autonomic, and cognitive changes with a strong neurobiological, psychological, and socioeconomic impact. It is estimated that it affects 50 million people worldwide, while nationally it has a prevalence of about 2%, being one of the most predominant neurological conditions. Therefore, due to its strong social, economic, and biological impact, it is essential to characterize the epidemiological profile and morbidity and mortality. **Objective:** To analyze the epidemiological profile of epilepsy and its morbidity and mortality in a hospital context in the state of Pará from 2014 to 2023. **Methods:** This is an ecological, exploratory and descriptive time series study, carried out through data extracted from the Hospital Information System, made available through the Department of Informatics of the Unified Health System (DATASUS), corresponding to hospitalizations for epilepsy in the state of Pará from 2014 to 2023. The variables collected were: age group, sex, color/race, number of hospitalizations, days of stay, total amount spent, and mortality rate. For comparison of the data published by DATASUS, searches were carried out for scientific articles that described such realities of the disease, being searched on the SciELO and LILACS platforms. **Results:** There was a total of 10,307 hospitalizations with a trend of increase over the evaluated period, in which the year 2023 corresponded to the highest number with 1,218 and 2015 with the lowest number with about 928 hospitalizations. Furthermore, the predominant color/race was brown, corresponding to 64% of the cases. In relation to sex, the prevalent was male with 56% of hospitalizations, while the most affected age group was 0-14 years with 47% of hospitalizations. The average length of stay was 4.7 days and the total amount spent during the period was 5,282,915.17, with 2023 being the year with the highest total expenditure of 971,704.56 and the lowest in 2015 with 323,891.69, representing a trend of increase in line with the increase in the number of hospitalizations. When analyzing the mortality rate, there was an average of 2.19, staying below the national and regional average of 2.48 and 2.2, respectively. In addition, there is a higher predominance of mortality in males over the age of 60 with an average mortality of 7.91. **Conclusion:** In summary, the epidemiological profile researched shows a higher prevalence in the age of 0-14 years of male sex and brown color/race with a trend of increasing number of hospitalizations and total amount spent. Likewise, a mortality rate was found below the national and regional average, but with a high risk in male patients over 60 years old. The characterization of this care profile favors the planning of actions that can provide early diagnosis and treatment of this so prevalent condition.

Epidemiological profile and public expenditure of hospital admissions for migraines in Brazil

Joanna Sousa da Fonseca Santana[1], Laura Carolina Costa Andrade[1], Humberto de Castro Lima Filho[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Joanna Sousa da Fonseca Santana; Email: joannasantana20.2@bahiana.edu.br.

Background: Migraine is a neurovascular condition with a high global incidence and is prevalent in Brazil, ranking as the third most common complaint in medical consultations and the fourth leading cause of emergency room visits. Its socioeconomic impact is substantial, leading to healthcare costs, productivity loss, and standing out as the primary cause of disability in individuals under 50 worldwide. Therefore, an analysis of the epidemiological profile of migraine hospitalizations in Brazil is needed. **Objective:** To analyze the epidemiological profile and public expenditures on hospitalizations for migraine and other cephalalgias in Brazil. **Methods:** This is a cross-sectional, epidemiological study using secondary data from the Brazilian Unified Health System Hospital Information System (SIH/SUS). The study covered the Brazilian territory from 2012 to 2022, including data on patients hospitalized for migraine and other cephalalgias (ICD codes G43 and G44) from SIH/SUS. The variables studied were sex, race/ethnicity, age group, year of hospitalization, average length of stay, total days of stay, and total public expenditures on hospitalizations per year. Statistical analysis and data tabulation were performed using Excel for Windows. **Results:** A total of 97,093 hospitalizations were recorded, with 33,234 (34.23%) involving male patients and 63,859 (65.77%) involving female patients. The age group with the highest hospitalization rate was 30-39 years (18.68%), followed by 20-29 years (18.21%). The lowest rate among adults was 50-59 years (8.79%). Whites had the most hospitalizations (40.98%), and Indigenous the least (0.06%). The average annual hospitalizations over the decade were 8,789.63 ± 1,850.54. The total expenditure over the decade was R$ 42,923,587.81, with an average of R$ 3,887,132.70 ± 1,402,110.54 per year. Additionally, out of the 97,093 hospitalizations, 6,019 were in the North region (6.20%), 26,904 in the Northeast (27.71%), 33,501 in the Southeast (34.50%), 25,544 in the South (26.31%), and 5,125 in the Midwest (5.28%). There were a total of 377,687 days of stay across all years, with an average stay of 3.9 days. Hospitalizations peaked in 2019 with a 48.86% increase over three years, followed by a 28.32% decline until 2021, then a 14.22% rise in 2022. **Conclusion:** The epidemiological profile of hospital admissions is closely linked to the prevalence profile of migraines. In Brazil, the annual number of migraine-related hospitalizations is significantly high, as is the average length of stay, resulting in a substantial cost to the Brazilian Unified Health System. Improved access to prophylaxis, education of non-specialist healthcare providers in diagnosing and treating simple migraines, and prudent resource utilization are necessary to enhance quality of care and reduce the burden on public healthcare. Significant public health and economic impacts underscore the need for better preventive care and resource management.

Epidemiological profile and temporal trends of meningococcemia in Brazil between 2010 and 2023

Ryan Lucas Barbosa Oliveira[1], Laís Souza da Silva Vitorino[1], Lorena Marques Ribeiro[1], Maria Danyelle Farias de Oliveira[1], William Correia da Silva Filho[1], Maryanne Maria Simplício Santos[1], Taíssa Kelly Novais Veiga[1], Mariana Araújo Oliveira Barbosa Rocha[1], Valdirene Maria de Barros Barbosa[2]

[1]Universidade Federal de Alagoas, Arapiraca AL, Brazil.
[2]Hospital Santa Marcelina, São Paulo SP, Brazil.

Correspondence: Ryan Lucas Barbosa Oliveira; Email: ryan.oliveira@arapiraca.ufal.br.

Background: Meningococcemia is one of the most severe and lethal clinical forms of meningitis, characterized by rapid progression to death due to shock, sepsis and disseminated intravascular coagulation. Therefore, it remains epidemiologically relevant. **Objective:** To describe the epidemiological profile of meningococcemia in Brazil from 2010 to 2023. **Methods:** This observational, retrospective, descriptive study utilized data from the Notifiable Diseases Information System (SINAN/SUS - DATASUS) covering 2010-2023, considering hospitalizations according to place of residence. The variables analyzed were sex, race, month, mortality rate, and year. The analysis was performed using Microsoft Office Excel® 2016 and Joinpoint Regression® 5.1 to determine the annual percentage change (APC) with a 95% confidence interval (CI). **Results:** Among the clinical forms of meningitis, meningococcemia was the most lethal (39.7%), followed by tuberculous meningitis (31.3%). From 2010 to 2023, hospitalizations were primarily among children aged 1-4 (21.2%), males (54.6%), and whites (41.7%). There were 5,757 hospitalizations, predominantly between May and September, peaking in 2010 (941 hospitalizations and 359 deaths). The years with the lowest number of hospitalizations occurred in 2021 (76 hospitalizations) and 2020 (108 hospitalizations). The 14-year analysis showed an annual reduction of -13.7% (APC:-13.7 | CI95%=-18.3,-11.7; p<0.001). By establishing an inflection point in 2021, there is a marked decrease from 2010 to 2021 (APC:-14.5 | CI95%= -23.8,-3.70; p=0.011), and an increase from 2021 to 2023 (APC:6.19 | CI95%= -37;30.1; p=0.697). São Paulo had the highest number of hospitalizations (45.1%), followed by Rio de Janeiro (16.8%), while Roraima and Amapá had the lowest (0.01% each). During the study, there were 2,287 deaths, yielding a national mortality rate of 0.07/100,000 inhabitants/year, higher in the 20-39 and 1-4 age groups. São Paulo and Rio de Janeiro had the highest mortality rates (0.397 and 0.395/100,000 inhabitants/year), while Roraima and Tocantins had the lowest (0.03 and 0.04/100,000 inhabitants/year). **Conclusion:** Hospitalizations and deaths declined significantly from 2011 onwards, likely due to the introduction of the meningococcal C vaccine in 2010 and its extension to adolescents aged 11-14 in 2018. The mortality rate was higher in states with more hospitalizations, such as São Paulo and Rio de Janeiro, suggesting a possible lack of notification in states with lower mortality and hospitalization rates, such as Roraima. The distribution of hospitalizations in the months mentioned shows a seasonal behavior, with a higher incidence in the autumn and winter periods. The lower hospitalization rates in 2020 and 2021 could be due to underreporting during the COVID-19 pandemic, warranting further analysis to confirm the increase from 2021 onwards.

Epidemiological profile and treatment efficacy of cladribine in a single Brazilian multiple sclerosis center

Breno Sousa Paiva[1], Fabio Victor Vieira Rocha[1], Daniel José Siqueira Tosi[1], Guilherme Valiate Picoli[1], Paula Zago Melo[2] , Bruno Batitucci Castrillo[1]

[1]Universidade Federal do Espírito Santo, Vitória ES, Brazil.
[2]Hospital Universitário Cassiano Antonio Moraes, Vitória ES, Brazil.

Correspondence: Fabio Victor Vieira Rocha; Email: fabio.vvrocha@gmail.com.

Background: Multiple sclerosis (MS) is a demyelinating disease of the nervous system with an autoimmune inflammatory mechanism, affecting the white matter of the brain, spinal cord, and optic nerve. Oral cladribine is a therapeutic alternative for patients with Relapsing-Remitting Multiple Sclerosis (RRMS), as it offers a convenient dosing regimen from the perspective of both patients and the healthcare system, being an oral medication with spaced doses and the lowest monitoring burden among treatments. Oral cladribine was approved in Brazil in 2019, but there is limited local data on clinical practice. **Objective:** To analyze the efficacy and persistence of cladribine treatment among Brazilian patients with multiple sclerosis in a Single Center. **Methods:** This is an observational, retrospective, and longitudinal study involving 10 MS patients treated with cladribine. The inclusion criteria were: diagnosis of relapsing-onset MS according to current criteria, and initiation of oral cladribine treatment at least 6 months before analysis. The main clinical data included disease activity (relapses and MRI follow-up), worsening of EDSS (Expanded Disability Status Scale), and adverse effects. **Results:** 10 patients treated with cladribine were included in the initial analysis, 9 (90%) being females. Median age at disease onset was 33 years (19-49), and on starting cladribine was 33.5 years (25-51). Median initial EDSS score was 2 (1-2.5). The main indications for cladribine use were: gestational desire in 7 (70%) patients; risk of Progressive Multifocal Leukoencephalopathy (PML) in 2 (20%) patients; and convenience in 1 (10%) patient. 80% of patients were naïve. After 15.5 months (7-39) of follow-up, 9 (90%) patients remained relapse-free, 9 (90%) did not show EDSS progression, 8 (80%) did not show MRI activity, and 8 (80%) were in NEDA-3. There were no treatment discontinuations. The minimum lymphocyte count reached a median of 1000.5 (510-1390), with 5 (50%) patients experiencing lymphopenia. Among those with lymphopenia, 4 (40% of patients; 80% of lymphopenias) had grade 2 lymphopenia, while 1 (10% of patients; 20% of lymphopenias) had grade 1 lymphopenia. The median time to the worst lymphopenia occurrence after starting cladribine was 9.5 months (range: 1-15). Additionally, 9 patients experienced side effects, with only one considered severe. **Conclusion:** The data demonstrate therapeutic success, with high efficacy and persistence of treatment among Brazilian MS patients, evidenced by 80% of patients achieving NEDA-3. The result is probably attributed to the high number of naïve patients (80%) in the sample, although there is a temporal limitation of the study.

Background: Brain neoplasms, although less frequent than other types of cancer, are notorious for their consumptive human impact, high mortality rates and the challenge they represent for the health system in view of the aging population. In the Brazilian context, the regional analysis of hospitalizations for brain neoplasms is essential to understand the epidemiological particularities and the specific challenges of each region. The Brazilian Northeast, a region marked by great socioeconomic disparities and difficulties in accessing specialized health care, represents a unique scenario in identifying epidemiological patterns and priority areas for interventions. **Objective:** To describe the epidemiological profile of hospitalizations for malignant neoplasia of the brain in the Northeast region of Brazil, analyzing data regarding age group, race/color, regime and type of care, length of hospital stay and geographic distribution in the period

from 2008 to 2023. **Methods:** It consists of a quantitative, observational and descriptive study based on secondary data from the Department of Informatics of the Unified Health System (DATASUS), of the Ministry of Health, on cases of hospitalizations for malignant neoplasia of the brain in the last 16 years (2008 to 2023). **Results:** During the 16 years observed, there were 43,727 hospitalizations for brain neoplasms in the Northeast of Brazil, corresponding to 20.3% of the total number of hospitalizations for this cause in the country. Of these, 81.0% were urgent, while at national level this figure was 76.5%. The average hospital stay in the region was 11.9 days, above the national average of 10.7 days; 26.9% occurred in the state of Pernambuco, 24.5% in Bahia and 17.5% in Ceará, 6.7% in Rio Grande do Norte, 6.3% in Paraíba, 6.3% in Piauí, 4, 1% in Maranhão, 4.0% in Alagoas and 3.6% in Sergipe. 57.2% of hospitalizations were mixed-race people; however, 35.0% did not have color/race information specified; 49.0% of hospitalizations were among individuals between 20 and 59 years old, 25.5% among individuals under 20 years old and 25.5% among individuals over 60 years old. **Conclusion:** There is a considerable incidence of brain neoplasia in the Brazilian Northeast when compared to the total number of Brazilian cases, representing a substantial part of the country's hospitalizations for this cause, highlighting the importance of this health problem in this region. Furthermore, the majority of hospitalizations occurred on an urgent basis in Pernambuco, Bahia and Ceará, indicating that some of these patients may already be in advanced stages of the neoplasia. The majority of hospitalizations were mixed-race people, with a considerable number of people without this specification and with an age range mainly between 20 and 59 years old. The importance of developing health policies aimed at screening and early diagnosis, as well as adequate treatment to reduce hospitalization rates for brain neoplasia, is highlighted.

Epidemiological profile of central nervous system neoplasms in the last decade

Bruno Ale Bark[1], Enzo Figueiredo Martineli[1], Samir Ale Bark[2], Bruno Henrique Mota Segnori[2], Guilherme Dorabiallo Bark[3]

[1]Universidade de Marília, Marília SP, Brazil.
[2]Faculdade Evangélica Mackenzie do Paraná, Curitiba PR, Brazil.
[3]Hospital do Rocio, Curitiba PR, Brazil.

Correspondence: Bruno Ale Bark; Email: brunoale.bark12@gmail.com.

Background: The epidemiological profile is one of the fundamental pillars of public health as it offers a detailed view of the health condition of a population. It is observed that central nervous system neoplasms have gained prominence as an area of significant epidemiological studies in the field of neuro-oncology. These neoplasms include a wide range of tumors, from benign to highly malignant, and their differentiation is crucial for choosing the therapeutic approach and prognosis, considering that they can cause irreversible or even fatal neurological damage. The causes of these tumors are diverse, with age, sex, race, epidemiological factors, and lifestyle habits being the main modulators for the development of neoplasms. **Objective:** To analyze the epidemiological profile of patients diagnosed with central nervous system neoplasms. **Methods:** A cross-sectional, retrospective, observational, and quantitative study was conducted through the statistical analysis of data on malignant and benign neoplasms of the brain and other parts of the central nervous system obtained from DATASUS - Department of Informatics of the Unified Health System, with the variables "sex," "age group," and "race," from January 2014 to January 2024. **Results:** Patients in the age group of 30 to 59 years resulted in 70,736 hospitalizations for malignant neoplasms and 14,126 for benign neoplasms. In the age group of 1 to 29 years, there were 49,386 hospitalizations for malignant neoplasms and 5,500 for benign neoplasms. Additionally, in the age group over 60 years, malignant neoplasms accounted for 55,527 hospitalizations, while benign neoplasms totaled 7,528 hospitalizations. Analyzing the variable: sex, it was observed that malignant neoplasms of the central nervous system are more prevalent in men 92,045 (52.05%) than in women 84,794 (47.95%). Conversely, benign neoplasms were more prevalent in women 14,939 (54.55%) than in men 12,445 (45.45%). Regarding race, the results showed a predominance in whites 77,103 (51.94%), followed by browns 63,640 (42.87%) in malignant neoplasms, while in benign neoplasms, the values obtained were, respectively, 12,963 (58.43%) and 8,300 (37.41%) in the brown and white races. **Conclusion:** The epidemiological profile is not merely an expression of data but a facilitator for understanding, planning, and implementing effective public health policies. The present study showed that the age group of 30 to 59 years is the most affected by central nervous system neoplasms, while malignant neoplasms affect males more and benign neoplasms affect females more. Similarly, an inversion was observed concerning race, with whites having a predominance of malignant neoplasms, while in benign neoplasms, the predominance occurs in browns. In light of this scenario, attention should be paid to these variables for both early diagnosis and effective therapeutic implementation.

[2]Universidade Estadual do Sudoeste da Bahia, Instituto Multidisciplinar em Saúde, Vitória da Conquista BA, Brazil.
[3]Faculdade Santo Agostinho, Vitória da Conquista BA, Brazil.

Correspondence: Emmanuel Santos Trindade; Email: emmanuelstrindade@gmail.com.

Background: Brain tumors are neoplasms of the Central Nervous System (CNS), characterized by abnormal cell proliferation in the region, which may include the cerebral hemispheres, hypothalamus, thalamus, basal ganglia, brainstem, cerebellum and meninges. According to data from the National Cancer Institute (INCA), 1.4 to 1.8% of all malignant tumors worldwide are in the CNS, with 70.9% of these in the cerebral hemispheres, brainstem and cerebellum. The annual incidence of CNS tumors is 4.85 per 100,000 in females and 5.61 per 100,000 in males. The highest occurrence is in patients over the fourth decade of life, with males being more affected in almost all types of CNS tumors. The symptoms of malignant brain neoplasms vary according to the location and size of the neoplasm, causing anything from headaches and seizures to permanent neurological deficits. **Objective:** To analyze the epidemiological profile of deaths due to brain cancer in Brazil between 2017 and 2021, according to the regions of the country. **Methods:** This is a descriptive study, examining the geographical distribution of deaths due to brain cancer in Brazil and its regions. A detailed analysis of the mortality from this disease throughout the Brazilian territory was presented using data from the Mortality Information System (SIM) in DATASUS for the period from 2017 to 2021, using the variables: processing year, age group, sex, ethnicity and region. **Results:** There were 40,983 deaths reported due to malignant brain neoplasms in Brazil from 2017 to 2021. The Southeast region accounted for the majority of deaths (44.3%), followed by the Northeast (22.3%), South (19.9%), Midwest (7.6%), and North (5.7%) regions. White individuals accounted for the majority of deaths (59.7%) overall. The predominance of white individuals was observed in the Southeast (67.1%), South (87.9%), and Midwest (53.3%) regions. This was not observed in the North and Northeast regions, where brown individuals were the majority, at 65.7% and 58.3%, respectively. There was a slight predominance in males, accounting for 52% of total deaths, which was evident in all regions. Regarding age groups, there was a lower number of deaths in the age group of 10 to 19 years (2.6%) compared to the age group of 0 to 9 years (3.3%). From the third decade onwards, the number of deaths increases until reaching a peak in the seventh decade of life (24.4%), after which the numbers start to decrease again. **Conclusion:** In view of the above, the epidemiological profile of deaths from brain cancer in Brazil between 2017 and 2021 was of male, white and elderly individuals, with the exception of the north and northeast regions, where the majority of deaths were of individuals brown. These findings are in agreement with the main population affected by malignant brain tumors and the advances in prevention, early detection, and treatment in younger patients.

https://doi.org/10.5327/CBN240700

Epidemiological profile of deaths from hereditary ataxias in Brazil from 2013 to 2022

Larissa da Silva Almeida[1], Guilherme Carvalho de Souza[1], Antonia Cardoso Silva[1], Julio César Soares Barros[1], Alícia Eduarda Rios Soares[1], André de Oliveira Paiva[1], Gabriela Barbosa de Sá Rocha[1]

[1]Universidade Federal de Alagoas, Maceió AL, Brazil.

Correspondence: Larissa da Silva Almeida; Email: larissa.almeida@famed.ufal.br.

Background: Hereditary ataxias are neurological disorders characterized by progressive dysfunction of the cerebellum and its connections, leading to issues with coordination and balance. This group includes subtypes such as spinocerebellar ataxias and Friedreich's ataxia, which can be genetically transmitted in an autosomal dominant, recessive or X-linked inheritance. Besides cerebellar ataxia, patients often exhibit a variety of neurological symptoms, including peripheral neuropathy and visual deficits. **Objective:** This study aims to investigate the epidemiological profile of deaths due to hereditary ataxias in Brazil from 2013 to 2022. **Methods:** This is a retrospective, cross-sectional, quantitative, and descriptive epidemiological study. Data were obtained from the Mortality Information System, focusing on deaths from 2013 to 2022 categorized under Hereditary Ataxia (G11) according to the ICD-10. The variables examined included region, race/ethnicity, sex, age group, and place of occurrence. After collection, the data were tabulated in Microsoft Excel for statistical analysis. **Results:** A total of 1,256 deaths were recorded from 2013 to 2022. Regional distribution included 50 deaths in the North, 260 in the Northeast, 459 in the Southeast, 377 in the South, and 110 in the Central-West. Among the deceased, 848 (67.5%) were identified as white. The distribution between sexes was equal, with 628 deaths each for males and females. The most prevalent age group was 60-69 years, with 265 deaths (21%), followed by the 50-59 years group with 244 deaths (19.4%). Finally, 845 deaths (67.2%) occurred in hospitals or other healthcare facilities, while 383 (30.5%) occurred at home. **Conclusion:** The analysis of the epidemiological profile of hereditary ataxias in Brazil highlights the need for more detailed research, particularly in regions outside the South-Southeast axis. This gap is critical as it contributes to the underreporting of cases in these areas, complicating the diagnosis and therapeutic management of affected patients. Therefore, a detailed epidemiological investigation across all regions is essential to improve clinical support conditions for hereditary ataxias.

https://doi.org/10.5327/CBN240701

Epidemiological profile of epilepsy hospitalizations among young people in Northeastern Brazil from 2013 to 2023

Italo Lafayette Silva[1], Gilberto de Paula Pinheiro Filho[1], Lucas Roque Evangelista[1], Nicolle Gabrielle Lima Silva[1], Henrique Katsumi Kawano[1], Dayanne Garcia de Freitas[1], Renan de Holanda Alves[1], Renato Vieira de Freitas Filho[1]

[1]Universidade Nove de Julho, São Paulo SP, Brazil.

Correspondence: Italo Lafayette Silva; Email: italolafayette@gmail.com.

Background: Epilepsy is characterized by a permanent predisposition of the brain to cause epileptic seizures, with significant neurobiological, cognitive, psychological and social repercussions. Hospital admissions are an important public health indicator, reflecting not only the incidence of specific medical conditions, but also epidemiological dynamics over time. This study focuses on the hospitalizations of young people, aged between 15 and 29, in the Northeast region of Brazil, exploring aspects such as geographical distribution, temporal trends and demographic characteristics. **Objective:** This study aims to identify patterns and trends in hospital admissions of young people in the Northeast region of Brazil, offering insights for public health policies aimed at the prevention and treatment of conditions affecting this age group. **Methods:** A cross-sectional, descriptive and quantitative epidemiological approach was used. Data on epilepsy-related hospitalizations in the Northeast region of Brazil, from January 2013 to December 2023, were obtained from the SUS Hospital Information System (SIH/SUS), made available by the Department of Informatics of the Unified Health System (DATASUS). The variables analyzed included information on geographic region, gender, race and age group. **Results:** During the period analyzed, the Northeast region recorded a total of 18,500 hospitalizations for the 15-29 age group. The year 2023 stood out with the highest number of hospitalizations, totaling 2,189 cases, marking a significant increase over the decade. This represents a percentage increase of approximately 45.15% compared to 2013, when 1,508 hospitalizations were recorded. Bahia led the way with the highest number of cases, totaling 4,684 (25.32%) over the period studied, while Sergipe recorded the lowest number of hospitalizations, with 378 (2.04%). The annual average of hospitalizations was approximately 1,682 cases. Together, Bahia and Pernambuco accounted for around 50.10% of the total number of cases analyzed. It is noteworthy that males predominated, with 9,836 (53.15%) hospitalizations, compared to 8,664 (46.84%) for females. In addition, individuals of brown ethnicity were the most frequently hospitalized, with around 11,801 (63.71%) cases. **Conclusion:** This study showed a significant increase in the number of hospitalizations over the decade, with 2023 recording the highest peak. There was a predominance of patients from Bahia and of brown ethnicity; however, there was no significant differentiation by gender among the patients.

Epidemiological profile of hospitalization for mental and behavioral disorders due to alcohol use in Brazil between the years 2019-2024

Vagner Costa da Cunha Júnior[1], Luana Cristina de Oliveira Lima[1], Maria Cecília Leal Menezes[1], Arthur Vinícius Feitosa Santos[1], Sabrina Sthéphanie Ataíde Martins[1], Thiago Pariz da Silva Dumas[1]

[1]Universidade Tiradentes, Aracaju SE, Brazil.

Correspondence: Vagner Costa da Cunha Júnior; Email: vccjr1@gmail.com.

Background: Alcohol is the legal drug most used by the world population, with repercussions related to symptoms of depression, anxiety and hypomania/mania during periods of intoxication and abstinence. Alcohol dependence has high rates among the user population, reaching a rate of 14.9%, followed by major depression (13%), dysthymia (4.9%), bipolar disorder (2%) and others. **Objective:** To analyze hospitalizations for mental and behavioral disorders due to alcohol use in Brazil and its regions from January 2019 to March 2024. **Methods:** Descriptive epidemiological study using secondary data from the SUS Hospital Information System (SIH/SUS) the Tabnet and data published in the Brazilian Institute of Geography and Statistics (IBGE), being tabulated in a spreadsheet in the Microsoft Excel program, according with data collected from hospitalizations during the period from January 2019 to March 2024. The variables analyzed were federative region, gender, ethnicity and age group. **Results:** In the period in question, there were a total of 161,021 hospitalizations for mental and behavioral disorders due to alcohol use, of which 139,631 (86.72%) were male patients. Furthermore, regarding the other parameters analyzed, it was possible to notice a higher prevalence of the condition under study in the white ethnic population (45.25% of cases), followed by mixed race (32.63%) and people without declared ethnicity (14, 29%), from the South region (2058.61 cases per one million inhabitants), which represents more than double the number of hospitalizations from the Central-West region (second most affected region, with 748.84 per one million inhabitants), and the age group that covers 30 to 59 years, with 124,439 cases (77.28%) in the period analyzed. **Conclusion:** After analyzing the results, it is concluded that the male population, mainly aged between 30 and 59 years old, white and resident in the southern region of the country, has a greater propensity to develop mental and behavioral disorders due to the use of alcohol. This trend can be explained by social factors, such as alcohol culture in the male population, as well as cultural and regional factors, such as German colonization in the South and the large production of alcoholic beverages in this region. All of these factors lead to an increase in alcohol consumption in the population, but end up having undesirable consequences in the long term. Therefore, we can see the need to create mechanisms to prevent alcohol abuse through the government, using public policies to raise popular awareness.

https://doi.org/10.5327/CBN240703

Epidemiological profile of hospitalization for Parkinson's in Brazil between the years 2014-2024

Luana Cristina de Oliveira Lima[1], Arthur Vinícius Feitosa Santos[1], Vagner Costa da Cunha Júnior[1], Sabrina Sthéphanie Ataíde Martins[1], Maria Cecília Leal Menezes[1]

[1]Universidade Tiradentes, Aracaju SE, Brazil.

Correspondence: Luana Cristina de Oliveira Lima; Email: luana.cristina0410@gmail.com.

Background: Parkinson's disease (PD) is the second most common pathology in the world that causes neural degeneration, second only to Alzheimer's. It causes progressive loss of neurons and its main characteristics are tremors and bradykinesia, which can manifest itself in motor and non-motor forms. PD occurs due to the progressive loss of dopaminergic neurons, leading to a decrease in dopamine, an important neurotransmitter that is present in the substantia nigra in the midbrain and is associated with the basal ganglia and other neurotransmitters, generating system dysfunction due to its lack. Furthermore, this disease manifests itself in all ethnic groups and social classes and, despite being prevalent in elderly people, it can affect young individuals. **Objective:** To analyze hospitalizations for PD in Brazil and its regions during the period from January 2014 to February 2024, through analysis of data from the Department of Information and IT of the Unified Health System (DATASUS). **Methods:** Descriptive epidemiological study using secondary data from the SUS Hospital Information System (SIH/SUS), Tabnet, and data published in the Brazilian Institute of Geography and Statistics (IBGE), being tabulated in Microsoft Excel, according to data collected from hospitalizations during the period from January 2014 to February 2024. The variables analyzed were federative region, gender, ethnicity and age group. **Results:** In the period analyzed, cases of admissions due to PD were 48.66 per million inhabitants in Brazil, with the South region (with 72.6% of its population being white) having the highest rate of hospitalizations - 92.66 per million inhabitants - and the North region (with 20.7% of its population being white) the lowest - 19.94 per million inhabitants. The total number of hospital admissions in the period analyzed was 9881 cases, with a higher prevalence in men (58.76%) and those of white ethnicity (54.04%). It is noteworthy that the majority affected group is made up of whites, mixed race people and those with no information (95.68%) and the most prevalent age group is individuals over 50 years old (89.55%).**Conclusion:** According to the results, it was found that hospitalizations for PD are more prevalent in men of white ethnicity and over the age of 50, factors that may be associated with greater susceptibility of this population to toxic agents, head trauma, hormonal issues, as well as cellular degeneration arising from the most advanced stage of the physiological and natural aging process at this stage of life. Finally, population analysis is important for directing public policies to assist cases of this disease.

Epidemiological profile of hospitalizations and deaths from multiple sclerosis in Brazil from 2019 to 2023

Caroline Patrícia Amaral Costa[1], Luan Daher Fernandes[2], Luiza da Paz de Souza[2], Suzana Gomes de Oliveira[2], Arley Nikson Oliveira Barreto[2], Moisés Cardoso Portilho[3], Luiz Carlos Figueiredo Filho[2], Luan Nascimento Pereira de Amorim[2]

[1]Universidade Federal do Pará, Belém PA, Brazil. [2]Universidade do Estado do Pará, Belém PA, Brazil. [3]Centro Universitário Metropolitano da Amazônia, Belém PA, Brazil.

Correspondence: Caroline Patrícia Amaral Costa; Email: caroline.costa@ics.ufpa.br.

Background: Multiple sclerosis (MS) is a chronic autoimmune disease that affects the central nervous system, which includes the brain and spinal cord. In multiple sclerosis, the immune system attacks myelin, a structure formed by a lipid membrane rich in glycophospholipids and cholesterol, which covers axons and is found in the white matter of glial cells. MS can take different forms, the most common being the recurrent remitting form, where symptoms can disappear completely between outbreaks, and the progressive form, where symptoms get progressively worse over time. Despite the fact that this pathology has no cure, treatments are available through the health system in order to improve the quality of life of users of the Unified Health System. **Objective:** To describe the epidemiological profile of hospitalizations and deaths from multiple sclerosis in Brazil between 2019 and 2023. **Methods:** This is an observational, descriptive and retrospective epidemiological study, with a quantitative approach, carried out by collecting secondary data from the Hospital Admissions System (SIH), from DATASUS, referring to each region of Brazil, in the time interval from 2019 to 2023. To build this epidemiological profile, the categories of deaths and hospitalizations were evaluated, as well as average values and their relationship with deaths. In addition, the quantitative data that make up each contingent in the subcategories of sex, race/color and age group were also used. The data was then organized and tabulated in Microsoft Excel 2021 software. **Results:** From 2019 to 2023, 27,586 hospitalizations and 170 deaths

were reported in Brazil, with annual averages of 5,517 and 34 cases, respectively. Of this total, the region with the highest prevalence of cases was the Southeast, with 20,790 (75.36%) hospitalizations and 24 deaths (14.11%). In terms of epidemiological indicators, there were 8,52 hospitalizations (30.89%) and 79 deaths among males (46.47%), and 19,062 hospitalizations (69.11%) and 91 deaths among females (53.52%). As for age group, the highest prevalence was in the 30-39 age group (n=7,739; 28.05%) for hospitalizations, followed by the 60-69 age group (n=47; 27.64%) for deaths. The ethnic group most affected was white, with 15,612 (56.81%) hospitalizations and 85 (50%) deaths. Thus, the most affected population was found to be white females, of economically active age and middle-aged, from the Southeast region. **Conclusion:** The findings highlight that genetic and environmental factors, as possible precursors of MS, are prevalent unevenly across Brazil, highlighting the need for awareness campaigns to promote early diagnosis and appropriate treatment to mitigate the rate of hospitalization and mortality.

Background: According to Caixeta (2012), Alzheimer's disease (AD) is a progressive neurodegenerative disease and the most prevalent of dementias in population-based clinical studies, with a prevalence and incidence of 50 to 75% of cases. This clinical condition is characterized by a gradual decline in intellectual and cognitive abilities. Most cases arise after the age of 65 (late-onset), but some may appear in younger individuals (early-onset Alzheimer's disease). **Objective:** This study aims to analyze the epidemiological profile of patients with AD in the Brazilian population over the past five years (2019 to 2023), corroborating or not with the current literature. **Methods:** This is a cross-sectional, descriptive, quantitative study, using data from January 2019 to December 2023. Data were collected from individuals diagnosed with the condition throughout Brazil, regardless of age group. Data collection was conducted through the Informatics Department of the Unified Health System (DATASUS), analyzing parameters such as total number of cases by region, color/race, sex, age, and deaths. **Results:** In Brazil, there were 7,867 cases of hospitalizations during the period from 2019 to 2023. Regionally, the Southeast was the most affected with 46.70% (n=3,674), followed by the South with 25.55% (n=2,010), Northeast 17.74% (n=1,396), Central-West 6.53% (n=514), and North 3.47%. Analyzing by color/race, the most affected was white with 50.56% (n=3,978), brown 26.42% (n=2,079), and black 4.51% (n=355). Regarding sex, the majority were female with 65.84% (n=5,180) and male with 34.16% (n=2,687). The number of hospitalizations due to AD by age group included patients aged 80 and over, comprising 59.73% (n=4,699). The age group 70 to 79 years represented 27.90% (n=2,195), together comprising 87.63%. Chronologically, there was a gradual increase in the number of hospitalizations per year, with 2019 (n=1,584), 2020 (n=1,199), 2021 (n=1,353), 2022 (n=1,627), and 2023 (n=2,014). During the same period, 1,892 deaths were recorded, with 57.82% in the Southeast region, followed by the South (20.45%), Northeast (11.95%), Central-West (7.61%), and North (2.17%). **Conclusion:** Epidemiological research on "age-related" diseases is essential because early pathological changes occur before symptoms. As observed, AD has a high incidence in Brazil, especially in the Southeast, mainly affecting white women over 70 years old, with a gradual increase over time. The disease, which usually begins late, impairs the quality of life by affecting cognitive functions such as recent memory. Awareness campaigns are crucial for earlier diagnoses due to its progressive nature.

Correspondence: Danilo Silva Nogueira; Email: danilo-nogg@hotmail.com.

Background: Viral meningitis is an infectious disease that affects the meninges, membranes that cover the central nervous system. It is caused by viruses, mainly from the Enterovirus group. In 2019, however, the SARS-Cov-2 virus spread globally, showing itself as a new cause of this syndrome due to the presence of the receptors for this pathogen in the cerebral vascular endothelium and the breakdown of the blood-brain barrier, leading to the development of this pathology. **Objective:** The present study is an analysis of the epidemiological profile of patients hospitalized for viral meningitis in the period from 2019 to 2021, which is described as the COVID-19 pandemic. **Methods:** This is a cross-sectional, descriptive, quantitative study, using notification data from all over Brazil, regardless of age group, from January 2019 to December 2021. Data collection was done through DATASUS (Sistema de Departamento de Informática do Sistema Único de Saúde), where the parameters of: total number of hospitalization cases by region, color/race, sex, and age were analyzed. **Results:** In the period from 2019 to 2021, 5,750 cases of hospitalization were notified. Of these, 51.37% (n=2,954) were registered in 2019 only, while in 2020, 26.33% (n=1,514) and 2021, 18.61% (n=1,070). At a regional level, cases in the Southeast region represent 41.74% (n=2,400), in the South region, 25.44% (n=1,463), Northeast, 20.45% (n=1,176), Central-West, 6.40% (n=376) and North, 5.82% (n=335). When comparing the states with the highest and lowest numbers, respectively, São Paulo, 29.98% (n=1,724) and Roraima, 0.09% (n=5) stand out. Among hospitalizations by color/race, 40.31% (n=2,318) correspond to white ethnicity, 33.37% mixed race (n=1,919), black 2.97% (n=171), yellow 1.53% (n=88) and indigenous 0.24% (n=14). As for data by sex, men correspond to 56.56% (n=3,252) and women to 43.44% (n=2,498). The age groups with the highest index were under 1 year old, 20.71% (n=1,191), 1 to 4 years old, 17.29% (n=994) and 5 to 9 years old, 12.49% (n= 718). **Conclusion:** The data reveals that during the COVID-19 pandemic there was a reduction in the number of cases of viral meningitis compared to previous years, with 51.37% of the total reported in the first year of the period, showing a significant decrease in the following two years. Among the regions, Southeast has the highest values, 41.74% of cases, with predominant rates in the state of São Paulo. Conversely, the North region has the lowest index. As for sex, men are more affected than women. In relation to age group, the most affected are children under 1 year old. In terms of race/ethnicity, white, brown, black, yellow and indigenous cases stand out in decreasing order of number. Finally, it is concluded that this reduction in the number of people affected is possibly due to underreporting, affecting regions that lack health services, as well as the mitigation in incidence due to the social isolation regime in place during the period.

Epidemiological profile of hospitalizations for central nervous system tuberculosis: a half-decade study across regions of Brazil

Luan Nascimento Pereira de Amorim[1], Bruno Kenji Hosoda Mineshita[1], Dangilla Ribeiro dos Santos[1], Fernando Lourenzo Rocha Vianna Oliveira[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Luan Nascimento Pereira de Amorim; Email: luanamorim010@gmail.com.

Background: Tuberculosis is an infectious disease caused by the bacterium Mycobacterium tuberculosis, which has tropism for the lungs, more precisely, the upper lobes. However, upon reaching the bloodstream, the extrapulmonary form can affect other organs, such as the Central Nervous System, and is then considered a severe form of the disease. **Objective:** To identify the epidemiological profile of hospitalizations for neurotuberculosis between regions of Brazil, from 2019 to 2023. **Methods:** This is a descriptive, cross-sectional and quantitative study, based on data from the Hospital Information System tabulated by the Information Technology Department of the Unified Health System (SIH/DATASUS), recorded from 2019 to 2023, in Brazil. Data were collected regarding ICD-10: tuberculosis of the nervous system. The variables for analysis were sex, age group and outcome, in addition to identifying the years and regions with the highest number of hospitalizations which, due to the lack of a population estimate for the year 2023, absolute data were used. Microsoft Excel 2021 software was subsequently used for calculations and analyses. **Results:** 1,629 hospitalizations for neurotuberculosis were recorded in Brazil from 2019 to 2023. Within the period studied, a reduction of approximately 13% in hospitalizations was noted from 2019 (n=325/19.95%) to 2021 (n=283 /17.37%), followed by an increase of approximately 27.62% until 2023 (n=391/24%). Almost half of the hospitalizations were concentrated in the Southeast region (n=770/47.27%), followed by the Northeast regions (n=292/17.93%) and the South (n=286/17.53%). Economically, the average value of hospitalizations for neurotuberculosis increased in the average value in the years 2022 and 2023, exceeding the amount of 3 thousand reais on average for each hospitalization. A predominance of males was identified (n=1068/ 65.56%) overall, it is worth highlighting that this proportion was present in all regions of Brazil. The age group between 30 and 39 years old concentrated the majority of cases (n=332/20.38%), followed by the age group between 40 and 49 years old (n=304/18.66%). In the outcome criterion, 193 deaths were recorded and a mortality rate of 9.21 in the year 2023, with its highest rate in the year 2022 (15.58) according to DATASUS. **Conclusion:** Therefore, the importance of screening for tuberculosis of the central nervous system is noted, given the increase in recent hospitalizations. Furthermore, it is important to understand the regions with the highest concentrations of cases so that it can assist in actions aimed at promoting health. Furthermore, despite the limitations found in this work, such as the lack of population estimates and data on treatment carried out, this does not nullify the research findings, such as the higher prevalence due to the profile: men aged 30 to 39 years, residing in the southeastern region of Brazil.

Background: Epilepsy is a neurological disease that occurs due to hyperactivity and dysregulation of neural activity, causing disordered electrical discharges. This pathology, which is characterized by recurrent seizures, is one of the most common neurological diseases in childhood and, worldwide, affects about 1 to 2% of the pediatric population. Therefore, the relevance of analyzing the epidemiological profile of epilepsy in children in Brazil is evident, given the prevalence of this pathology in childhood, as well as its negative impact on the quality of life of affected children. **Objective:** To analyze the epidemiological profile of childhood epilepsy in Brazil between 2019 and 2023. **Methods:** This is a cross-sectional, quantitative, descriptive and observational research, with data from January 2019 to December 2023, collected through the SUS Hospital Information System, obtained on the DATASUS platform. The total number of hospitalizations for epilepsy in the age group between 0 and 14 years of age in Brazil were analyzed, considering the variables: region, year, age group, sex, color/race, total hospital expenses, type of care, average stay and deaths. **Results:** Of the total of 110,891 hospitalizations for epilepsy in children aged 0 to 14 years in Brazil, the Southeast was the most affected region (33.6%), and the North the least affected (7.06%). In 2022, there was the highest number of hospitalizations (23,748) and, in 2020, the lowest number (19,604). Of the type of care, 93.5% were urgent. It was identified that brown individuals (50.4%), males (55.2%) and in the age group between 0 and 4 years (42.1%) were the most affected by the disease. The average length of hospital stay, in days, was 5.2, and 611 deaths were recorded in the period analyzed. **Conclusion:** The majority of hospitalizations for epilepsy in childhood occurred in the Southeast, in 2022, on an emergency basis and in brown boys aged between 0 and 4 years. Therefore, the high prevalence of epilepsy in children in Brazil highlights the importance of implementing public policies aimed at preventing situations that cause epileptic seizures and managing these seizures, in order to reduce the number of hospitalizations due to this cause.

Epidemiological profile of hospitalizations for neurocysticercosis by regions of Brazil 2013-2022

Pedro Ferreira de Souza Evangelista[1], Emmanuel Santos Trindade[2], Indira da Silva Felício[1]

[1]Faculdade Santo Agostinho, Vitória da Conquista BA, Brazil.
[2]Universidade Estadual do Sudoeste da Bahia, Vitória da Conquista BA, Brazil.

Correspondence: Pedro Ferreira de Souza Evangelista; Email: pedro.evvan@gmail.com.

Background: Neurocysticercosis is the most common parasitic infection of the central nervous system (CNS), caused by the Taenia solium larva, known as Cysticercus cellulosae. Man is the definitive host and pigs are the intermediate hosts. When it invades the nervous tissue, the cysticercus undergoes degeneration, accompanied by an intense inflammatory response, which can vary in degree and occur in different places, such as the subdural space, choroid plexus or ventricular wall. This degeneration process can result in intracranial hypertension, dementia, meningitis, hydrocephalus, stroke and permanent neurological damage. **Objective:** To estimate the number of reported cases of neurocysticercosis in Brazil from 2013 to 2022. **Methods:** This is a descriptive study to evaluate the geographical distribution of hospitalizations caused by neurocysticercosis, ICD B69.0, in different parts of the country. It presents a detailed analysis of hospitalizations resulting from this pathology distributed throughout the Brazilian federative units, which were stratified by sex, ethnicity and age group, using data from the DATASUS database, within the SIH/SUS Hospitalization Segment from 2013 to 2022. **Results:** Between 2013 and 2022, 2,534 hospitalizations for neurocysticercosis were recorded in Brazil. 55.92% of hospitalizations were of male individuals. This male predominance occurred in all years, with the exception of 2022, when 51.18% of hospitalizations were female. Regarding ethnicity, there was a higher proportion of hospitalizations of brown (39.82%) and white (28.57%) people at the expense of black (3.87%), yellow (1.74%) and indigenous (0.24%). However, 25.77% of hospitalizations did not present information regarding the patients' ethnicity. The age groups, in descending order of hospitalizations, were 40-49 years old (20.17%), 50-59 years old (18.27%), 30-39 years old (17.40%), 20-29 years old (12.23 %), 60-69 years (12.12%), 70-79 years (7.14%), 10-19 years (6.75%), 0-9 years (3.99%) and 80 years or over (1.93%). It is noticeable that hospitalizations are concentrated in middle age, with a reduction as they approach the extremes of age, which is in line with the natural history of the disease, as, although normally acquired in childhood, clinical manifestations take time to establish themselves, thus requiring hospitalization normally in adulthood. **Conclusion:** Based on the findings, it is possible to notice a predominance of brown, middle-aged male individuals among hospitalizations for neurocysticercosis in Brazil between 2013 and 2022. These findings reinforce those found in the literature, considering it is a predominant disease in rural areas, with precarious hygiene and basic sanitation conditions.

https://doi.org/10.5327/CBN240710

Epidemiological profile of hospitalizations for Parkinson's disease in brazil from 2012 to 2022

Isabella Queiroz Barbosa[1], Pedro Ferreira de Souza Evangelista[1], Gabriel Lédo Pereira de Oliveira[1]

[1]Faculdade Santo Agostinho, Vitória da Conquista BA, Brazil.

Correspondence: Isabella Queiroz Barbosa; Email: qbisabella@hotmail.com.

Background: Parkinson's disease (PD) is a neurodegenerative pathology that mainly affects the elderly and whose clinical manifestations involve the motor system with resting tremor and muscle rigidity. This condition has a multifactorial etiology that results in the degeneration of dopaminergic neurons in the substantia nigra. In Brazil, PD contributes significantly to hospital admissions, especially in relation to complications such as falls, severe motor crises and aspiration pneumonia. In addition, its high prevalence among the elderly population increases mortality rates. **Objective:** To analyze the epidemiological pattern of hospitalizations for PD in Brazil from 2012 to 2022. **Methods:** A descriptive analysis was carried out to assess the geographical distribution of hospitalizations caused by PD (ICD G20) in Brazil. The DATASUS database was used, which was segmented by age group, gender and ethnicity, within the Hospital Information System (SIH) segment, from 2012-2022. **Results:** From 2012 to 2022, the number of hospitalizations due to PD increased from 398 to 791 per year, an increase of 98.74%, totaling 7,427 cases in that period. The Southeast region had the highest number of hospitalizations (53.27%), while the Midwest had the lowest (3.54%). In terms of age group, those aged 60 and over accounted for the majority of hospitalizations (73.67%), which indicates a higher prevalence in older age groups and highlights the need for health care for the elderly. In terms of gender, men had more hospitalizations than women in all the years analyzed, with a total of 4,321 (58.16%) for men and 3,106 (41.84%) for women. As for color/race, white people accounted for the majority of admissions (64.94%), followed by brown (29.62%) and black (4%). **Conclusion:** Analysis of the results shows that the increase in hospitalizations during the period in question reflects the increase in the incidence of the disease, possibly due to better identification and recording of PD cases. The geographical distribution shows a more evident concentration in the southeast region, indicating regional disparities in access to health services or in the prevalence of the disease. The predominance of hospitalizations among individuals aged 60 and over highlights the vulnerability of the elderly population to PD. In addition, the differences observed between the sexes, with a higher proportion of hospitalizations among men, and between different racial groups, with a predominance of hospitalizations among white people, suggest that biological and socioeconomic factors may influence the incidence and severity of the disease.

Epidemiological profile of hospitalizations for viral encephalitis in Brazil from 2014 to 2023

Fernando Gabriel dos Santos Santiago[1], Erick Antonio Rodrigues Mendes[1], Lucas Miquilini de Arrudas Farias[1], Savio Roberto Silva Costa[1], Danusa Neves Somensi[1], Mariangela Moreno Domingues[1], Emanuel de Jesus Soares de Souza[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Fernando Gabriel dos Santos Santiago; Email: fernando_gsantiago@outlook.com.

Background: Viral encephalitis is defined as inflammation of the brain parenchyma with neurological dysfunction of infectious or autoimmune origin, encephalitis has predominantly viral etiology, notably the Herpes virus (HSV-1 and HSV-2), followed by enteroviruses, varicella-zoster and other unknowns, whose frequencies vary in a multifactorial way. A large part of the population is seropositive for most encephalitis pathogens, which, via hematogenic or nervous routes, spread during periods of host immunosuppression, after a state of latency, as in the reactivation of HSV-1, latent in the trigeminal ganglia after primary infection. **Objective:** To determine the epidemiological profile of hospitalizations for viral encephalitis in Brazil between 2014 and 2023. **Methods:** This is a cross-sectional, descriptive and quantitative study, carried out from data extracted from the Hospital Information System of SUS (SIH/SUS) of the Department of Informatics of the Unified Health System of Brazil (DATASUS). The variables used were sex, age group, ethnicity, region, number of services per year, average length of stay and total amount spent. Data analysis was performed using the Biostat 5.3 software. **Results:** There were a total of 19,972 cases of viral encephalitis recorded in the period from 2014 to 2023. The most affected profile was male, in the age group of 1 to 4 years, in the brown cord. The most affected Brazilian region was the North, with 8,279 hospitalizations for viral encephalitis, about 41.45% of the total cases. With the exception of the year 2013, in which only 123 hospitalizations were recorded, this quantity maintained a heterogeneous pattern, with its maximum peak in 2019 with 2,452 records and minimum peak in 2020, with 1,644. The average length of stay fluctuated between 9.2 days, in the Midwest region, and 11.8 days, in the Southeast region, where hospitalizations also had higher mortality. In the analyzed period, about 40 million reais were spent due to these cases. **Conclusion:** This study showed that the profile most affected by hospitalizations for viral encephalitis in

the period from 2013 to 2024 was male, in the age group of 1 to 4 years, in the brown cord. In this 10-year period, cases of viral encephalitis totaled almost 20,000 hospitalizations. These cases were distributed heterogeneously over this period, showing little variation. There was no predominance of greater impact in a specific region, as all were impacted in different ways, such as the North region with the highest number of cases, the Northeast region with the longest stay and the Southeast region with the highest mortality, still showing little variation among themselves. This constant in the distribution of hospitalizations, whether in the temporal aspect or in the regional aspect, demonstrates the magnitude of the importance of this pathology, reinforcing the need to foster its research and treatment.

https://doi.org/10.5327/CBN240712

Epidemiological profile of hospitalizations for viral meningitis in Brazil between the years 2019-2024.

Arthur Vinícius Feitosa Santos[1], Thiago Pariz da Silva Dumas[1], Vagner Costa da Cunha Júnior[1], Luana Cristina de Oliveira Lima[1], Maria Cecília Leal Menezes[1], Sabrina Sthéphanie Ataíde Martins[1]

[1]Universidade Tiradentes, Aracaju SE, Brazil.

Correspondence: Arthur Vinicius Feitosa Santos; Email: arthur.vinicius04@souunit.com.br.

Background: Viral meningitis is a neurological condition that generally evolves benignly. It usually presents with an acute onset of fever, headache, photophobia, neck stiffness and, frequently, nausea and vomiting, although younger children may not show signs of meningeal irritation. It can occur alone or in outbreaks and affects people of all ages, being more common in children under five years of age. Approximately 85% of cases are caused by Enteroviruses, including Poliovirus, Echovirus and Coxsackievirus. **Objective:** To analyze hospitalizations due to viral meningitis in Brazil during the period from January 2019 to March 2024. **Methods:** Descriptive epidemiological study using secondary data from the SUS Hospital Information System (SIH/SUS), Tabnet, and data published in the Brazilian Institute of Geography and Statistics (IBGE), being tabulated in Microsoft Excel, according to data collected on hospitalizations and deaths during the period from January 2019 to March 2024. The variables analyzed were federative region and age group. **Results:** In the period analyzed, the rate of hospitalizations for viral meningitis was 50.76 per million inhabitants in Brazil. The data demonstrated that children aged 0 to 9 years represent 51.98% of total cases of the disease, the prevalence of which decreases with increasing age of the population, whereas the elderly (people aged 60 or over) represented only 4.27 % of cases. Furthermore, it should be noted that cold weather is a factor that contributes to greater infectivity of the meningitis virus. That said, in the Northeast and North regions, 40.20 and 35.57 cases were recorded per million inhabitants, respectively, while in the South region 89 cases were recorded per million inhabitants. **Conclusion:** According to the analysis of the results, the younger population has a higher prevalence (51.68% of all cases) of hospitalizations for the disease. Also, it is possible to conclude that viral meningitis is related to an immature immune system, as the number of cases decreases drastically with increasing population age. Additionally, it is necessary to reinforce that this situation occurs equally in all brazilian states, showing that it is associated with viral meningitis. Furthermore, the literature demonstrates that there is a clear tendency for people to stay together at home, especially during colder periods. This behavior, along with the decrease in the effectiveness of the immune system due to the cold, corroborates the increased infectivity of viruses. This is evidenced by the fact that the number of hospitalizations in the Southern states more than doubles compared to those in the North and Northeast. Finally, it is important that public policies are created aimed at children in the fight against viral meningitis, focusing mainly on those who live in cold regions of the country.

Background: Meningitis is included in the National List of Compulsory Notifiable Diseases in Brazil and is defined as an inflammatory process affecting the membranes surrounding the brain and spinal cord. It presents with meningeal syndrome characterized by neck stiffness, fever, and headache, and may also show signs of meningeal irritation such as Brudzinski and Kernig signs. **Objective:** To outline the epidemiological profile of meningitis in Brazil from 2014 to 2023. **Methods:** This is an epidemiological, descriptive, and retrospective study conducted through the electronic platform from the Informatics Department of the Public Unified Health System (DATASUS). The population assessed included all patients affected by meningitis in Brazil over the past 9 years. To achieve the study objectives, the information from the patients was categorized according to age, sex, race, and location. The information used in this epidemiological study was obtained from a secondary database, and submission to an Ethics Committee was not required. **Results:** Various etiologies were evaluated and compared by age group, sex, and race over the past 9 years: meningococcemia (MCC), meningococcal meningitis (MM), meningococcal meningitis with meningococcemia (MM+MCC), tuberculous meningitis (MTBC), meningitis due to other bacteria (MB), unspecified meningitis (MNE), viral meningitis (MV), meningitis due to other etiologies (MOE), Haemophilus meningitis (MH), and pneumococcal meningitis (MP). During this period, a total of 144,001 cases of meningitis were diagnosed. Of note, viral meningitis (MV) predominated across all age groups from <1 year to 64 years, accounting for 63,590 cases (~44.16%), predominantly affecting males with 84,544 confirmed cases (~58.72%), and the black race with 67,466 confirmed cases (~46.9%). **Conclusion:** Regarding meningitis and its main subtypes, the epidemiological study revealed that viral meningitis was the most prevalent in Brazil over the past 9 years. Additionally, the disease was more common in males and among individuals of black race. These findings underscore the need for more active epidemiological surveillance and health promotion and prevention actions targeted at the most affected groups.

Background: Meningitis is an inflammation of the membranes covering the brain and spinal cord, mainly affecting the arachnoid space and occasionally impacting the cranial or spinal regions. Without treatment, meningitis has a fatality rate (TL) between 50% and 80%. With treatment, this rate is reduced to around 15%. Infectious meningitis represents an important challenge for Brazilian public health, and are diseases for which notification is mandatory. **Objective:** To detail and investigate the epidemiological profile of meningitis cases reported in southern Brazil between 2019 and 2023. **Methods:** This is an observational, descriptive and quantitative ecological study, with data collected from the Notifiable Diseases Information System (SINAN), on the DATASUS platform, in May 2024. The variables were investigated: total notifications, notifications from each federative unit, sex, age group, color or race, level of education, frequent etiology and evolution throughout the region (Rio Grande do Sul, Santa Catarina and Paraná) between January 2019 and December 2023. **Results:** Between 2019 and 2023, 13,686 cases of meningitis reported in the southern region were identified. Of these, 6,345 (46.3%) were in the state of Paraná, making it the most affected area, 3,400 (24.84%) in Santa Catarina and 3,941 (28.8%) in Rio Grande do Sul. The data indicate a higher incidence among men (58.32%), children under 1 year old (19.22%) and 40-59 years old (17.70%), and predominantly white (78.95%). Regarding education, 10% of those affected had completed high school. The most common etiology was viral (44.41%). Regarding the outcome, 78.94% were discharged from hospital. **Conclusion:** Public policies aimed at preventing meningitis must be widely implemented. In the South region, they should be mainly focused on the state of Paraná, on white children under 1 year of age. Early diagnosis is important for a hospital discharge prognosis.

Epidemiological profile of multiple sclerosis in Brazil: an analysis of the last 5 years (2019-2023)

Background: Multiple sclerosis (MS) is a chronic disease that causes the demyelination of the myelin sheath, it is an autoimmune disease, with its etiology being diverse and still heavily researched. MS causes neurological disabilities and affects young patients, most of them in the age range of 20 to 40 years. It causes a variety of symptoms,

such as fatigue, muscle weakness and paresthesias, as well as visual, cognitive, and mental alterations, and presents in three forms: relapsing-remitting, secondary progressive, and primary progressive. The first type being present in 85% of cases. For MS diagnosis, it is used the McDonald's 2017 criteria involving clinical aspects, imaging, and analysis of cerebrospinal fluid with specific markers. **Objective:** To analyze the epidemiological characteristics of the patients affected by multiple sclerosis between 2019 and 2023. **Methods:** Ecological and descriptive study, using data collected from the Brazilian Unified Health System Hospital Information. Were collected informations on sex, race, region of origin, type of care (elective or emergency), hospitalization rate, and mortality for the years 2019 to 2023. **Results:** There were 27,577 hospitalizations for Multiple Sclerosis (MS) in Brazil, with the year 2022 having the highest number of cases (26.46%, n=7,299). These hospitalized patients were mostly in emergency care (52.31%, n=14,427). The Southeast region presented the highest frequency (75%, n=20,786) of cases, while the North region was the least frequent (1.33%, n=367). The analysis revealed a higher occurrence in females (69.10%, n=19,057), with the most affected age group being between 30 and 39 years (28.04%, n=7,735). Whites accounted for 57% of hospitalizations (n=15,609), while those of indigenous origin accounted for only 0.01% (n=4). In addition, it is worth noting that 10% of cases (n=2,767) did not contain information on race. The average mortality rate of MS was 0.61%, peaking in 2018 with a representation of 1.13%, and the lowest number in 2022 with 0.45%. Regarding the mortality rate by age group, there is a gradual and direct proportional increase with age, the highest percentage is in patients who are over 80 years old at 16% and the lowest percentage is between 15 and 29 years old at 0.13%. **Conclusion:** Between 2019 and 2023, there are significant differences in the mortality rate and hospitalizations due to Multiple Sclerosis depending on the year of registration. Age is an aggravating factor and there is a big discrepancy depending on region. Regarding race, the possibility of information bias related to databases should be considered, with possible underreporting and/or differences in access to healthcare services among the studied populations. However, further studies are needed to understand the relationship between epidemiological data and patient characteristics in order to advance treatment, diagnosis, and patient support.

Epidemiological profile of multiple sclerosis inpatients in Brazil in the last 10 years

Tainá Reis Martins[1], Wívian Maria Pires Figueredo[1], Mariana Guimarães Mundim[1], Karina Andrade de Prince[1]

[1]Centro Universitário FIPMoc, Montes Claros MG, Brazil.

Correspondence: Tainá Reis Martins; Email: taina2002@hotmail.com.

Background: Multiple sclerosis (MS) is an immunomediated, demyelinating and neurodegenerative disease of the central nervous system. The first symptoms of MS tend to appear between 20 and 40 years of age, representing the main cause of non-traumatic neurological disability in young adults. In Brazil, it is estimated that about 40,000 individuals live with the disease, but there are weaknesses and obstacles in the Brazilian epidemiological data due to late diagnosis, the difficulty of classifying the disease and the limited access to centers specialized in the diagnosis and treatment of MS. **Objective:** To analyze the epidemiological profile of patients who required hospitalization for MS in the last 10 years in Brazil. **Methods:** This is a descriptive, retrospective, ecological time series study. It had as a research universe the database of the Hospital Information System of SUS (SIH/ SUS), made available by the Department of Informatics of SUS (DATASUS) number of hospitalizations and hospital expenses per MS in Brazil from January 2014 to December 2023. The variables analyzed were gender, hospital cost, nature of care, average hospitalization rate and deaths. **Results:** In the period analyzed, a total of 43,950 hospitalizations were reported, with a higher number recorded in 2022 (16.6%), and a significant increase in the number in 220% (4,464) in the last 10 years. Hospitalizations predominated in females, representing 69.6% (479,643), that is, 2.2 times more than men, being the common age group between both sexes more affected from 30 to 39 years, with 28.7% (12,645). The region with the most hospitalizations was the southeast with 70.5% (31,006). The mortality rate over these years decreased 11.9% (9.4 to 8.3), in contrast, it is noteworthy that the highest mortality rate occurred in males, with index 1.1 and rate approximately 103% higher than for women. In addition, the group with the highest mortality was 80 years or more, with an index of 11, and the northern region with the highest mortality rate, with an index of 2.6. Regarding the nature of the visits, 53.7% (23,617) of the visits were urgent. The highest total number of hospitalizations was in 2023 (R$ 3,649,310.85), with an increase from 2014 to 2023 of 118% (R$ 1,980,724.00). The female gender comprised 66.5% (R$ 16,498,959.12) of the expenses of the total value. The average value of hospitalization decreased 31.8% (R$ 262.89). **Conclusion:** The epidemiological profile more incident were women from 30 to 39 years old. Currently the number of hospitalizations and the total value cost is increasing, while the average values per hospitalization decrease significantly. Although they are not the most affected population, residents of the North Region and males have higher mortality, and the reasons for this should be analyzed, either by precarious care, availability of resources, and biological susceptibility or self-neglect.

Epidemiological profile of muscle disorders: insights from a specialized service in São Paulo

Filipe Tupinambá Di Pace[1], Cristiane Araújo Martins Moreno[1], Clara Gontijo Camelo[1], Raquel Diógenes Alencar Sindeaux[1], Karlla Danielle Ferreira Lima[1], Marco Antônio Veloso Albuquerque[1], Alullin Fonseca[1], Rodrigo de Holanda Mendonça[1], André Macedo Serafim Silva[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Filipe Tupinambá Di Pace; Email: filipedipace@gmail.com.

Background: Neuromuscular diseases (NMDs) are conditions characterized by primary dysfunction of muscles, neuromuscular junction, nerves or motor neurons. Understanding the distribution and frequency of these conditions is important for improving diagnostic and therapeutic approaches. **Objective:** To provide an epidemiological profile of patients attending a specialized muscle service. **Methods:** Data obtained between November 2020 and February 2024 were automatically extracted from electronic medical records and revised by an examiner. Key data points included patient registration, birth date, sex, genetic test results, disease topography, and diagnosis. **Results:** There were 5160 appointments and a total of 1526 patients, of them, 55% were male, the mean age was 31(0-88) years, and 62.6% were adults. The muscle was the most frequent topography (63%), and the top diagnosis was dystrophinopathy (24.8%). Regarding other muscle diseases, the most common diagnoses were congenital muscular dystrophy (11.3%), mitochondrial myopathy (8.9%), congenital myopathy (8.4%), and limb-girdle muscular dystrophy (7.9%), and when a genetic test was conclusive mostly of them were respectively related to LAMA2, TK2, RYR1, and DYSF. Myotonic dystrophy accounted for 7.4% of cases, all of them due to DMPK expansion. Facioscapulohumeral muscular dystrophy (3.3%) included one patient with type 2 disease. Metabolic myopathies (2.3%) and channelopathies (2.2%) were mainly caused by glycogenosis and congenital myotonia, respectively. Other inherited myopathies made up 2,8% of the cases, mostly myofibrillar myopathy secondary to DES pathogenic variant, and 6 patients with hereditary inclusion body myositis, including 4 with the pathogenic variant in ANXA11. Inflammatory myopathy was the most frequent non-genetic diagnosis (3.8%), and an atypical presentation and/or family history motivated a genetic test in 15.5% before the final diagnosis. Congenital myasthenia (2.9%) was mostly related to CHRNE pathogenic variants. Although the clinic is aimed at myopathies, other neuromuscular conditions were also seen during this period: Inherited neuropathies (4.2%) mostly included Charcot-Marie-Tooth disease (54%) and acute hepatic porphyria (28%). For motor neuron diseases (13%), spinal muscular atrophy was the predominant diagnosis (72.3%), followed by amyotrophic lateral sclerosis and non-5q spinal muscular atrophy. An undefined diagnosis was present in 14.1% of cases, in which 43.5% had at least one inconclusive genetic test. **Conclusion:** The data offers valuable insights into the epidemiology of muscle diseases in São Paulo. The high rate of genetic diseases and the significant proportion of undefined diagnoses underscores the need for advanced genetic testing with availability to the population, and research to identify novel mutations. Improved diagnostic tools and therapeutic strategies tailored to the specific profiles of the local population could enhance patient outcomes.

[6]Santa Casa de Misericórdia de Limeira, Limeira SP, Brazil.

Correspondence: Victória Stephane Tessaro; Email: stephanetessaro.2020@gmail.com.

Background: Parkinson's disease (PD) is a degenerative, chronic, and progressive disorder of unknown etiology that affects the central nervous system. Its primary symptoms include bradykinesia, tremors, muscular rigidity, and postural instability. The main cause of the disease is the death of cells in the substantia nigra, which produces dopamine, a neurotransmitter that controls movement. Studies indicate that the incidence of PD increases with age. **Objective:** To characterize the epidemiological profile of PD in Brazil over the past 10 years. **Methods:** A retrospective, descriptive, and cross-sectional epidemiological analysis was conducted using data provided by the Department of Informatics of the Unified Health System of the Ministry of Health (DATASUS/MS). **Results:** The results showed that PD accounted for a total of 629 deaths and 9,991 hospitalizations in the last 10 years, with a notable concentration in the southern and southeastern regions, and its peak incidence occurred in 2023. The age group with the highest number of deaths was 80 years and older, with a significant mortality rate of 14.65%, while the age group of 70 to 79 years surpassed others in hospitalizations (2,645). There was a higher prevalence of mortality among females (6.82%), particularly in the northern region, whereas males predominated in hospital admissions (5,876), especially

in the southeastern region. The Black (13.06%) and Yellow (7.83%) races also exhibited higher rates of morbidity and mortality compared to other racial groups. **Conclusion:** It can be concluded that mortality rates were higher among elderly individuals aged 80 years and above, particularly in females and in the northern region. Conversely, hospitalization rates were higher among males in the 70 to 79 age group, especially in the southeastern region. Additionally, morbidity and mortality were higher in non-White races. These findings are important for informing public health policy decisions regarding PD based on the observed trends during this period.

Epidemiological profile of patients hospitalized for tetanus in Brazil over the last 10 years

Pedro Henrique de Vilhena[1], Júlia de Oliveira Bessegatto[1], Alisson Rafael de Oliveira Pereira[1], Rodrigo Ferreira de Moura[1]

[1]Universidade Federal de Lavras, Lavras MG, Brazil.

Correspondence: Pedro Henrique de Vilhena; Email: phdvilhena@gmail.com.

Background: Tetanus is an acute poisoning caused by the neurotoxins produced by Clostridium tetani. Infection occurs by the inoculation of spores into the skin or mucous membranes, mainly through wounds. Although the treatment of the disease can be carried out with support, antibiotic therapy, and neutralization of the toxin, only the complete vaccination schedule followed by reinforcement with adult bacterial duo (adult dT) every 10 years confers lasting immunity. Thus, knowledge of the epidemiological panorama of patients hospitalized for tetanus may indicate the population profile most vulnerable to infection. **Objective:** To analyze the epidemiological profile of patients hospitalized for tetanus in Brazil. **Methods:** A retrospective study was conducted using secondary data recorded in SINAN, SI-PNI, and SIH available in DATASUS from 2013 to 2022, analyzing notifications, hospitalizations, sex, color/race, age group, type of care, deaths, average hospitalization costs, and adult dT vaccination coverage. **Results:** A total of 2291 cases of accidental tetanus were confirmed in the study interval, 1825 (79%) hospitalizations and 335 (15%) deaths. The average number of cases per year was 230, with 90% of the cases being urgent. The total cost of hospitalization was R$11,321,436, about R$6,203 per hospitalization. Spending on males represents 85% of this amount, which is explained by the proportion of cases by gender, with 4.4 times more cases occurring in men. The average expenditure/hospitalization rate maintained greater proximity between the sexes. In terms of race/color, there was a change in trend with a reduction in hospitalizations by whites in 2020 (APC: -32.04, 95%CI: -45 to -11, p<0.001). A reduction in the number of cases was observed in the "no information" group, with an increase in the brown group and a small peak in 2019 in the black group. Thus, of the total set, 26% of the cases did not have identification information, whereas the most affected identified themselves as brown (42%) and white (27%). As for the regional analysis, Minas Gerais (MG), Rio Grande do Sul (RS) and Paraná (PR) together represent 27% of the country's cases, while Roraima (RR) and Tocantins (TO) have the lowest number (<1%). By extension, MG and RS had the highest number of deaths, although when analyzed proportionally, RR, Amapá (AP) and RO reached lethality rates above 50%. These data also reflect adult dT vaccination coverage. The number of confirmed cases was negatively correlated with adult dT vaccination coverage (Kendall= -0.23; p<0.08). The age groups 50-59 years (24%) and 60-69 years (20%) groups were more hospitalized and received the lowest adult dT booster doses. **Conclusion:** Brown men aged between 50 and 69 years living in MG and RS in emergency care represent the social group with the lowest vaccination coverage and the greatest vulnerability to tetanus.

https://doi.org/10.5327/CBN240720

Epidemiological profile of patients who death from Alzheimer's disease in Salvador – Bahia: 2013 to 2023

Ana Beatriz de Oliveira Andrade[1], Juarez Pereira Dias[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Ana Beatriz de Oliveira Andrade; Email: anabeandrade@hotmail.com.

Background: With the aging of populations, chronic non-communicable diseases gain notoriety, especially dementia - syndromes with a progressive and generalized decline in cognitive functions, the most recurrent being Alzheimer's disease (AD), an irreversible degenerative neurological disease, with behavioral and affective disorders. **Objective:** To analyze the epidemiological profile of patients who died from AD in Salvador - Bahia in the period from 2013 to 2023. In addition to describing deaths by sex, age group, annual distribution, temporal trend, spatial distribution by health district and analyzing characteristics. **Methods:** A descriptive study was conducted with secondary data obtained from the Mortality Information System on the website of the SUS Department of Information Technology. The variables used were: number of cases per year of notification and health district of residence, sex, age group, race/skin color and education. The variables were analyzed according to their absolute and percentage distribution. Pearson's Chi-Square test and Simple Linear Regression were used, with statistical significance set at p<0.05. Statistical storage and analysis were performed using the Statistical Package for Social Sciences. **Results:** During the study period, 3,087 deaths from AD were recorded in the population over 60 years of age in Salvador. Most deaths occurred in females, 2,248 (72.56%), and in the age group over 80 years, 2,471 (79.76%). The mortality rate increased by 286.01% during the study. The Health District with the highest average rate was the Historic Center (38.35/100,000 inhabitants). There was an increase as the age groups advanced, with the majority of those affected being over 80 years of age (99.13/100,000 inhabitants). There was an increasing trend between the sexes, with a prevalence of males among the youngest and females over 80 years of age. The highest frequency of deaths was in the white race/skin color, 1,481 (47.80%). In addition to the prevalence among those who had eight to eleven years of schooling, 733 (23.66%). **Conclusion:** AD is a major public health problem. Its increasing incidence in recent years is a reflection of aging, better access to resources and information, and improvements in diagnostic methods. In this scenario, early diagnosis, training of health professionals, clinics and hospitals, and technological advances in the scientific field are imperative.

https://doi.org/10.5327/CBN240721

Epidemiological profile of patients with Guillain-Barré syndrome from 2013 to 2023 in the Federal District, Brazil

Maria Regina Saddi Guerra[1], Fernanda Massue Komatsu Rabelo[1], Fernanda Carneiro e Cardoso[1], Maria Fernanda Alves Barros[1], Mariana Santos Vogel[1], Ana Clara Monte Varandas[1], Cayara Mattos Costa[2]

[1]Universidade Católica de Brasília, Brasília DF, Brazil.
[2]Universidade Federal do Maranhão, São Luís MA, Brazil.

Correspondence: Maria Regina Saddi Guerra; Email: mreginasaddi@gmail.com.

Background: Guillain-Barré syndrome (GBS) is an autoimmune disease characterized by demyelination or axonal degeneration of peripheral nerves, resulting in muscle weakness or loss of sensation. In Brazil, from 2008 to 2014, were recorded 15,512 hospitalizations, showing the relevance that this syndrome has on the health of the Brazilian population, as it not only compromises patients' quality of life, but also has a considerable impact on the health system due to the need for prolonged hospitalizations and intensive care. **Objective:** Describe the epidemiological situation of GBS in the Federal District (DF) between the years 2013-2023. **Methods:** Ecological time series study using data from the "Sala de Situação-Infosaúde" platform of the Health Department of the Federal District in the Hospital Information System database, CID G61.1 (Guillain-Barré syndrome) from 2013 to 2023. The variables investigated in the Federal District (DF) were: total hospitalizations, year of prevalence, nature of the intervention, gender, age group, length of stay, prevalence among hospitals and procedures. **Results:** In the period analyzed, there were 460 hospitalizations, with an average of 48.2 hospitalizations per year. From 2013 to 2017, the average number of hospitalizations was 32 per year, however there was a sudden increase in hospitalizations in 2018, a pattern that remained constant until 2023, a period in which the average was 50 per year. Regarding the nature of the intervention, there is a predominance of urgency (90.65%) over elective (9.35%). In the gender variable, there was a higher rate of male patients (58.7%) compared to female patients (41.3%). In terms of hospitalization authorizations by age group, there was a higher prevalence in the 15 to 19 year old range (47). The Ceilândia Regional Hospital has the longest average length of stay (27.5 days), followed by the Guará Regional Hospital with (18.07 days). The highest number of hospitalization authorizations per health establishment was at Hospital de Base do Distrito Federal (267), followed by Hospital Regional da Asa Norte (34). In relation to hospitalization authorizations by administrative region of residence, there was a predominance of those from the Ceilândia region (52) and in relation to those residing outside the DF, there was a predominance of inhabitants of the municipality of Luziânia (13). The most commonly performed procedures were the treatment of polyneuropathies (347) and Acute Demyelinating Polyradiculoneuritis (81). **Conclusion:** The study showed the predominance of hospitalizations for GBS in the Federal District from 2013 to 2023: men, between 15 and 19 years old, with elective hospitalization, at the Hospital de Base of the Federal District and with the treatment procedure of polyneuropathies. This study highlights the need for new actions aimed at intervention and treatment of this disease, both acute and late management with sequelae.

Epidemiological profile of patients with headache in neurology outpatient clinics in the Southern region of Santa Catarina

Camila Pezente Dal Toe[1], Debora Dagostin Casagrande[1], Tatiana Pizzolotto Bruch[1], Natalli Studnicka[1], Maria Laura Zanette Naspolini[1], Natália Effting Crema[1]

[1]Universidade do Extremo Sul Catarinense, Criciúma SC, Brazil.

Correspondence: Camila Pezente Dal Toé; Email: camilapezente@hotmail.com.

This study aimed to evaluate the clinical and epidemiological profile of patients with headache treated at neurology outpatient clinics of the Brazilian Unified Health System (SUS) in the cities of Criciúma, Forquilhinha, and Içara, Santa Catarina. A total of 212 medical records were analyzed, predominantly from female patients (77.4%) with a mean age of 47.01 years. The majority of cases (87.7%) were classified as primary headaches, with migraine being the most common form (31.1%), followed

by Tension-Type Headache (5.7%). The research did not find significant abnormalities in imaging studies related to headache. Regarding the association with COVID-19, only 32.4% of patients reported worsening or onset of headache after contact with the virus. These findings suggest that primary headaches, particularly migraine, are prevalent in trained neurology outpatient clinics, with little evidence of significant impact. This study contributes to understanding the profile and clinical characteristics of headache in the population served by SUS in the southern region of Santa Catarina, emphasizing the importance of epidemiological studies to guide public health policies.

https://doi.org/10.5327/CBN240723

Epidemiological profile of patients with multiple sclerosis from 2013 to 2023 in the Federal District, Brazil

Maria Regina Saddi Guerra[1], Marcela Pontes Paulo[1], Sarah dos Reis Alves de Paiva[1], Guilherme Lacerda Oliveira[1], Vinícius Turial Assis dos Santos[1], Gabriel Ferreira de Jesus Malta[1], Cayara Mattos Costa[2]

[1]Universidade Católica de Brasília, Brasília DF, Brazil.
[2]Universidade Federal do Maranhão, São Luís MA, Brazil.

Correspondence: Maria Regina Saddi Guerra; Email: mreginasaddi@gmail.com.

Background: Multiple sclerosis (MS) is an autoimmune neurological condition characterized by an abnormal immune response that causes inflammation and damage to the myelin sheaths of the central nervous system. Today, the disease affects 2.8 million people worldwide and it is estimated that 40 thousand people have this disease in Brazil. Due to the multiplicity of symptoms and long-term debilitating consequences, the study of MS is essential for the technical and theoretical improvement of the disease. **Objective:** To outline the epidemiological profile of patients diagnosed with MS in the Federal District from 2013 to 2023. **Methods:** This was an ecological time-series study using data from the public platform "Sala de Situação-Infosaúde" of the Health Department of the Federal District in the database of the Hospital Information System (SIH) of ICD G35 (multiple sclerosis) between the years 2013-2023. The total number of hospitalizations, age group, sex, prevalence among administrative regions, the nature of the intervention, the average length of stay and the cost were analyzed. **Results:** There were 2437 hospital admissions due to MS in the observed period, of which 74.39% were female and 25.61% male. The age distribution prevails in the range of 20 to 49 years of age (80.18%), with emphasis on the group of 40 to 44 years of age (17.23%). The origin of MS patients is concentrated in four administrative regions of the Federal District (35.82%): Ceilândia, Taguatinga, Samambaia and Plano Piloto, respectively, in order of prevalence. From 2013 to 2018, the number of hospitalizations increased progressively, with 782 in 2018 (32.08%). In 2019, there was a sudden drop in the number of hospitalizations (27), which continued throughout 2020 (25) and only recovered between 2021 (241) and 2022 (506), most likely as an effect of the spread of the SARS-CoV-2 virus. In 2023, the values decrease again with 31 hospitalizations, possibly arising from administrative and operational changes at SES-DF. Of the total number of hospitalizations, 58.6% were urgent and 41.4% were elective, with a single hegemonic prevalence in clinical beds (99.17%) and an average length of stay of 1.56 days. Costs totaled 615,587.48 reais during the period. **Conclusion:** The epidemiological profile of the patients was, for the most part, between the ages of 40 and 44, female, residents of administrative regions with a high population, with elective care and length of stay of 1.56 days. The importance of public policies aimed at caring for patients with MS, as well as specialized support centers, is highlighted.

https://doi.org/10.5327/CBN240724

Epidemiological profile of patients with neurotuberculosis in Brazil over the last 5 years

Marcela dos Santos de Deus[1], Mariana Aires Silva[1], Pedro Keemper Rocha Alpino[1], Jéssika Yumi Taba Ono[1], Maria Clara Caparroz Cassioti[1], Maria Luiza Leme Camargo[1], Danielli Casonato da Silva[1], Luah da Silva Ishikawa Manhani[1], Luana Fornetti Castilho Cazani[1], Maiara Silva Tramonte[1]

[1]Universidade Nove de Julho, Bauru SP, Brazil.

Correspondence: Marcela dos Santos de Deus; Email: marcela.dsdd@uni9.edu.br.

Background: Neurotuberculosis is a bacterial infection caused by Mycobacterium tuberculosis, affecting the Central Nervous System (CNS). The dissemination occurs when the bacteria enter the bloodstream and cross the blood-brain barrier. CNS TB commonly occurs in individuals previously treated for pulmonary TB years earlier, due to reactivation of latent infection. The primary infection, usually acquired by inhaling droplets containing bacilli, can lead to dissemination to the meninges and brain surface. Bacilli can remain latent in tubercles, which may rupture into the subarachnoid space, triggering tuberculous meningitis, the main clinical presentation of neurotuberculosis. **Objective:** Analysis of the epidemiological profile of patients with neurotuberculosis in Brazil over the past 5 years. **Methods:** This is a descriptive and retrospective epidemiological study with quantitative analysis between 2019-2023. Data were obtained from the Department of Health Informatics of the Unified Health System (DATASUS) and articles available in the National Library of Medicine (NIH) PubMed. The analysis considered variables such as region, sex, race/ethnicity, age group, number of deaths, and mortality rate. Data were collected in April 2024. **Results:** During the analyzed period and location, 1,629 hospitalizations of patients diagnosed with neurotuberculosis were recorded. There was a variable trend over the years, with a progressive decrease in cases in 2019 (325), 2020 (322), and 2021 (283), followed by an increase in 2022 (308) and 2023 (391). The southeast region registered the highest number of hospitalizations (770), followed by the northeast (292) and south (286) regions. Among ethnic groups, individuals of mixed race (755) were the most affected, followed by white (497) and black individuals (113). Regarding sex, men accounted for the majority of hospitalizations, totaling approximately 65.6%. In terms of age group, the most affected groups were those aged 20-29 years (233), 30-39 years (332), 40-49 years (304), and 50-59 years (259). The mortality rate per hospitalization was 11.8%. Furthermore, it is noteworthy that the mortality rate remains higher in the southeast region (13.51), among individuals of mixed race (11.39), although it is higher in females (12.48), and increases with advancing age group. **Conclusion:** The results show that neurotuberculosis is a serious public health problem, with variations in the number of hospitalizations over time. Despite fluctuations, there is a general upward trend, highlighting the importance of continuous surveillance and intervention. The Southeast region has the highest number of cases and a higher mortality rate. Vulnerable groups include men, people of mixed race, and certain age groups. These findings underscore the need for specific prevention and control strategies, especially in these areas and populations most affected, to reduce both the incidence and mortality of neurotuberculosis.

Correspondence: Oliver Reiks Miyajima; Email: oliver.miyajima@aluno.uece.br.

Background: Multiple sclerosis (MS) is an autoimmune disease causing demyelination of central nervous system (CNS) that affects mainly young adults, with strong female preponderance. This disease is characterized by recurrent episodes of neurological dysfunction, such as weakness in the limbs, impaired vision and poor coordination, and causes significant disability after onset. A small percentage of MS diagnoses occur before the age of 18 years, with slower progression than in adults due to neuroplasticity, but capable of generating moderate-to-severe disability at a younger age. **Objective:** To analyze the data available on the DATASUS platform about the hospitalizations by MS in children aged 0-19 years in Brazil over the ten years 2014-2023 and provide epidemiological relevant information. **Methods:** This is a cross-sectional, descriptive and retrospective study. Data were extracted from the Hospital Morbidity System (SIH/SUS – DATASUS) from the years 2014 to 2023 considering the number of hospitalizations due to MS in children aged 0-19 years in Brazil according to place of residence. The variables analyzed were region of the country, sex, age, race, deaths and year of hospitalization. **Results:** Between 2014-2023, there were a total of 2,628 hospitalizations, with the largest share occurring in the southeast, 1,728 (65.75%), and the smallest share in the north, 61 (2.32%). In the south, between 2021 and 2023, cases increased by 56.1%. In addition, in the northeast region, in the total period analyzed, they increased by 275%. Among the states, the ones with the most hospitalizations were São Paulo 1,140 (43.37%) and Minas Gerais 452 (17.19%). Of all the cases, there was only one death (0.0038%), and this was a male in the 15-19 age group. The predominant gender in hospitalizations was female, with 1,689 cases (64.26%), while males accounted for 939 cases (35.73%). The most affected pediatric age group was 15-19 years old with 2060 cases (78.38%), followed by 10-14 years old with 478 cases (18.18%), 5-9 years old 81 cases (3.08%), 1-4 years old 7 cases (0.26%) and under 1 year old 2 cases (0.07%). Among the races, whites accounted for the majority of hospitalizations with 1,399 cases (53.23%), while the smallest race with recorded hospitalizations was yellow with 24 (0.91%). There were no hospitalizations recorded for the indigenous population. The year with the most hospitalizations was 2022 with 367 cases (13.96%), and the lowest was 2014 with 137 cases (5.2%). **Conclusion:** Although the pediatric age group represents a small number of MS diagnoses, there has been an increase in the number of hospitalizations over the years, with a predominance of females and a later age in adolescence. In addition, even with the predominance of cases in the southernmost regions of the country, the large increase in the northeast region is noteworthy. Further studies on the subject are needed in order to provide a better understanding.

Epidemiological profile of transient ischemic stroke (CVA) and related syndromes in adults and elderly people in Northeast Brazil from 2018 to 2023

Luana Cristina de Oliveira Lima[1], Arthur Vinícius Feitosa Santos[1], Vagner Costa da Cunha Júnior[1], Sabrina Sthéphanie Ataíde Martins[1], Maria Cecília Leal Menezes[1]

[1]Universidade Tiradentes, Aracaju SE, Brazil.

Correspondence: Luana Cristina de Oliveira Lima; Email: luana.cristina0410@gmail.com.

Background: Stroke is one of the main causes of death and disability in the world, especially in low and middle income countries. It is characterized by interruption of blood flow to an area of the brain, resulting in tissue damage. Ischemic stroke, responsible for approximately 85% of cases, occurs due to the occlusion of a cerebral artery, usually by a thrombus or embolus. Its risk factors include high blood pressure, diabetes mellitus, smoking, hypercholesterolemia and atrial fibrillation. **Objective:** To analyze cases of transient ischemic stroke and other related syndromes in adults and elderly people in Northeast Brazil between January 2018 and December 2023 through analysis of data from the Department of Information and Informatics of the Unified Health System (DATASUS). **Methods:** Descriptive epidemiological study using secondary data from the SUS Hospital Information System (SIH/SUS), Tabnet, and data published in the Brazilian Institute of Geography and Statistics (IBGE), being tabulated in Microsoft Excel, according to data collected from cases registered during the period from January 2018 to December 2023. The variables analyzed were state, sex, race/ethnicity and age group over 20 years old. **Results:** In the period analyzed, registered cases of transient ischemic stroke were 615.76 per million inhabitants in the Northeast. The states with the highest prevalence per 100,000 inhabitants are Alagoas (191.81), Maranhão (88.13) and Pernambuco (80.45); and the lowest are Sergipe (16.2), Paraíba (23.7) and Rio Grande do Norte (30.15). Furthermore, there was a higher prevalence in males (53.14%), mixed people (51.07%) and those aged over 50 years (60.88%). Finally, the highest number of deaths occurred in the states of Sergipe (21.42%), Paraíba (12.74%) and Maranhão (12.23%) and, in relation to age group, individuals over 80 years old are the most affected (29.68%), followed by those aged 70 to 79 (28.19%) and aged 60 to 69 (20.56%). **Conclusion:** Based on the results, mixed men over 50 years of age have a higher prevalence of transient ischemic stroke, which can be correlated with a sedentary lifestyle, high blood pressure, diabetes and family history, which can lead to arterial clogging, representing risk factors. Furthermore, the states with the highest number of deaths are those with the lowest number of hospitalizations, in the case of the states of Sergipe and Paraíba, suggesting disparity in access to health services, especially in highly complex ones. Finally, it is necessary to implement public policies, highlighting the importance of recognizing clinical signs and implementing prevention strategies in order to reduce sequelae and improve prognosis.

Epidemiological profile of traumatic cervical spinal cord injury in Northern Brazil: a 10-year retrospective analysis.

Maria Cândida Barros Arantes Romano[1], Júlia Oliveira e Freitas[1], João Lazaro da Silva Rodriguez Oquendo[1]

[1]Centro Universitário Presidente Antônio Carlos, Araguaína TO, Brazil.

Correspondence: Maria Cândida Barros Arantes Romano; Email: candinha_barros-ar@hotmail.com.

Background: The traumatic spinal cord injury (SCI) consists in a break of the spinal medulla, being ocasioned by a traumatic event that might cause the loss of function, be it, motor, sensible ou autonomic in a way which may be transitory or irreversible. The condition of a medullar injury varies according to the affected portion of the spine, being the main manifestations, the paralysis or paresys of the limbs, alteration in the muscle tone, alteration in the superficial and profound reflexes, among others. Spinal cord injury is not subject to notification, with little epidemiological data and published work. The worldwide incidence of SCI is estimated between 9 and 50 cases/million inhabitants. **Objective:** The study aimed to analyze patients hospitalized with spinal cord injury of the cervical region in the north of Brazil, using data from the SIH/SUS to understand the profile and associated factors. **Methods:** This is a descriptive, quantitative and retrospective study with 918 victims of cervical spinal injury, between the years 2012 and 2022, in the states of Pará, Tocantins, Rondônia, Amazonas, Acre, Roraima and Amapá. Data from the SUS Hospital Information System (HIS/SUS) was used as a source. The variables sex, age, treatment and condition were studied. **Results:** The data consists of 82.4% male patients and 17.5% female patients, with 20 to 35 years being the age group with the highest prevalence of cervical SCI. Regarding the incidence by state, there is a higher occurrence in the state of Pará (48%), followed by Rondônia (19%) and Tocantins (12%). Furthermore, there is also a preference for conservative treatment in 69% of cases. **Conclusion:** The group at highest risk for cervical spinal cord trauma are young men, with a higher prevalence in the state of Pará and the most adherent treatment is conservative. Therefore, the occurrence of cervical SCI in the northern region is significant, requiring improvement in the quality of pre-hospital and hospital care for these patients to reduce the risks and consequences of emergency surgeries, which can lead to irreversible sequelae. Furthermore, there is a need for epidemiological studies and notifications about spinal cord injury and its causes, especially in the northern portion of the country, for subsequent prevention planning.

Epidemiological study of cases of ischemic stroke in a hospital of Minas Gerais: an observational study

Letícia Aparecida de Figueiredo[1], Isabela Pinto Braga[1], Mauro Eduardo Jurno[1], André Brasil Tollendal[1], Denise Suemy Rocha Hashimoto[1]

[1]Centro Hospitalar de Barbacena, Barbacena MG, Brazil.

Correspondence: Isabela Pinto Braga; Email: isabela.braga7@gmail.com.

Stroke is an important cause of morbidity and mortality worldwide, being the second most common cause of death in Brazil and worldwide. Considering the impact of the disease related to failures in hospital care, a Stroke Unit was implemented in an institution at the state of Minas Gerais in June 2022 with expectation of improvements in management of those cases. The goal of this study was to outline the epidemiological profile of stroke victims in a Hospital at the state of Minas Gerais from October 2022 to December 2023. This is a cross-sectional observational study based on the evaluation of medical records of patients treated during this period. The total number of patients with suspected stroke/TIA was 277 patients. The average age was 68.5 years and the predominant sex was 58% male. Regarding the presence of comorbidities, the most prevalent diseases present in admitted patients were hypertension, diabetes mellitus, dyslipidemia and congestive heart failure. Regarding admission, it was observed that the NIH score was applied to 44.2% of admitted patients, with the average score on this scale being 9. The average time between admission and imaging was 79.5 minutes. In this service, the Stroke Unit was created in June 2022, and since then it has gradually brought improvements to provide complete and effective care for patients in the region. The analysis shows demographic data with similar numbers compared to the numbers encountered in Brazil. Data on comorbidities prior to admission slightly differed from the rest of the Country. Data such as door-to-image and door-to-needle times and data related to rehabilitation and mortality were discrepant between the service studied and the rest of Brazil, which may reflect, among other reasons, prolonged tomography maintenance time, delay in dispensing medications and reduced number of professionals in the multidisciplinary team.

https://doi.org/10.5327/CBN240995

Epidemiological study of live births with spina bifida in Brazil

Camila Pugliesi de Figueiredo[1], Victor Pedrosa Ferreira de Souza[1], Amanda Mendes Santos[1], Michelle Oliveira Teixeira[1], Wânia Rezende Lima[1]

[1]Universidade Federal de Catalão, Catalão GO, Brazil.

Correspondence: Camila Pugliesi de Figueiredo; Email: camila.figueiredo@discente.ufcat.edu.br.

Background: Spina bifida (SB) is a congenital defect, resulting from the incomplete closure of the neural tube between the 3° and 4° week of pregnancy, impacts life quality in the baby, causing, for example, motor disabilities. Although there are important genetic patterns that contribute to the prevalence of neural tube defects, it is known that factors, such as folic acid supplementation, are of the utmost importance in their etiology. **Objective:** To evaluate the epidemiological scenario of live births with spina bifida and fetal factors in Brazil. **Methods:** It's a retrospective descriptive epidemiological study of live births with spina bifida, based on data from the Congenital Malformations, Deformities and Chromosomal Anomalies Monitoring Panel. The data from 2014 to 2024 was analyzed, with the results from 2023 and 2024 being preliminary. The data used is from public domain sources, thus there is no need to submit the work to the National Research Ethics Commission (CONEP) and analysis by the Research Ethics Committee (CEP) system. The variables included were gestational duration, delivery type, Apgar Score from the first and fifth minute, birthweight, sex and skin color. **Results:** Of the live births with SB, 722 were diagnosed in 2014, 689 in 2015, 821 in 2016, 787 in 2017, 795 in 2018, 743 in 2019, 671 in 2020, 718 in 2021, 704 in 2022, 718 in 2023 and 225 in 2024 (up to the most recent June update). On the gestational duration, 2265 babies were premature, with 7 being extremely premature and 5280 were born at term. This information was ignored in 48 cases. Regarding the delivery type, the most prevalent was c-section (6,306), corresponding to 83% of the total, while only 1,276 were vaginal (16.8%). The data was marked as blank or ignored in 11 births. As for the APGAR, in the first minute, 485 babies had an APGAR of 0 to 2, 601 of 3 to 4, 1787 of 5 to 7, and 4633 of 8 to 10, with 87 marked as blank or ignored. In the fifth minute, 244 live births had an Apgar score of 0 to 2, 124 of 3 to 4, 660 of 5 to 7, 6471 of 8 to 10, with 94 as blank or ignored. Concerning birthweight, 71.5% of live births weighed 2500g or more, 21.5% weighed 1500 to 2499g, and 6.9% weighed less than 1500g; Only 2 births had this data ignored or left blank. Considering the sex, 3838 were male, 3549 were female and, in 106, this information was absent. Furthermore, the skin color was marked as brown in 51.7%, white in 37%, black in 6.7%, yellow in 0.4% and 0.4% were indigenous. This information was blank in 3.7% of live births. **Conclusion:** The year with the highest number of SB live births was 2016. Most births were cesarean sections, although around 17% were vaginal deliveries. It is crucial to emphasize that a baby born with spina bifida requires greater care. Therefore, a reasonable percentage of live births were premature, had low birth weight or had a low APGAR at the 5th minute, indicating asphyxia. Finally, the majority of those born were brown and male.

Epidemiological study on multiple sclerosis hospitalization in Brazil comparing sex, age and region between January 2008 to December 2023

Maria Eduarda Medeiros Martins[1], Lucca Ferdinando Queiroz Fernandes[1], Diógenes Emanuel Dantas da Silva[1], Matheus Araújo de Medeiros[1], Arthur Rebouças de Souza[1], Tiago Lameque de

Sousa e Silva[1], Amanda Lima Sampaio[1], Claúdio de Souza Fernandes Júnior[1], Pedro Henrick Guimarães Carvalho[1], Iury Hélder Santos Dantas[1]

[1]Universidade Federal do Rio Grande do Norte, Caicó RN, Brazil.

Correspondence: Maria Eduarda Medeiros Martins; Email: mariaeduardammartins1209@gmail.com.

Background: Multiple sclerosis (MS) is a chronic autoimmune disease of the central nervous system, characterized by inflammation, demyelination, and neurodegeneration. MS is known to present with diverse clinical manifestations and can lead to significant disabilities in affected individuals. Despite its relatively low prevalence compared to other neurological diseases, there is a growing recognition of MS as a significant health problem, which highlights the need for comprehensive epidemiological studies to better understand its impact. **Objective:** To conduct an epidemiological analysis of hospitalizations due to MS in Brazil between 2008 and 2023. **Methods:** Data were obtained from the Notifiable Diseases Information System (SINAN) of the Ministry of Health, and analyzed to identify the number of hospitalizations for multiple sclerosis in Brazil between 2008 and 2023, including analyses by year, region, sex, and age group. **Results:** Regionally, the Southeast Region had the highest concentration of hospitalizations, representing 67.0% of the total, followed by the South (15.6%), Northeast (8.4%), Central-West (7.1%), and North (1.9%) regions. There was a significant variation over the years, with hospitalizations gradually increasing from 2008, when 1,682 cases were recorded, reaching a peak in 2022 with a total of 7,299 cases. Regarding gender, women accounted for a higher number of hospitalizations, representing 69.0% of the total, while men accounted for 30.0%. In terms of age group, the majority of hospitalizations occurred in young adults, especially in the 20 to 49-year age range, which represented 73% of the total. There was a gradual decrease in hospitalizations with increasing age, with only 437 cases recorded in individuals aged 80 and over. Among children under 5 years old, there were only 13 hospitalizations, equally distributed between boys and girls, highlighting the low incidence of MS in this age group. **Conclusion:** This study highlights the complexity and diversity of the impact of MS in Brazil, emphasizing the need for more effective and targeted public health policies for early diagnosis, appropriate treatment, and continuous support for patients, especially in the most affected regions and groups. However, there is a need for additional studies on the subject, particularly to improve the organization of resources dedicated to the treatment and prevention of hospitalizations due to multiple sclerosis.

[2]Hospital de Base do Distrito Federal, Brasília DF, Brazil.
[3]Universidade de Rio Verde, Faculdade de Medicina, Rio Verde GO, Brazil.
[4]Hospital Sírio Libanês, Brasília DF, Brazil.
[5]Instituto Brasileiro de Neuropsicologia e Ciências Cognitivas, Brasília DF, Brazil.

Correspondence: Isabel Oliveira Araujo Moraes; Email: isaoraujo@outlook.com.

Background: This study is part of the project: Prodromal and Overt Parkinson's Disease Epidemiological Study in Brazil (PROBE-PD), which aims to determine the prevalence of Parkinson's disease (PD) and other parkinsonian syndromes in individuals aged 60 and over within a population sample from the North, Northeast, South, and Midwest regions. **Objective:** To present partial results regarding the prevalence of PD, parkinsonism, and REM sleep behavior disorder (RBD) in the community of Candangolândia-DF, Midwest region. **Methods:** This study, approved by the Research Ethics Committee of the Beneficent Society of Ladies Hospital Sírio-Libanês (CEPesq/HSL-5.482.147), is conducted in two phases. In Phase I, screening is carried out using the Tanner Questionnaire, wherein volunteers respond to nine yes-or-no questions related to motor symptoms, and the Single-Question Questionnaire for RBD (RBD1Q). A positive screening is indicated by either two affirmative responses on the Tanner Questionnaire or one on the RBD1Q, prompting an invitation to Phase II, where participants undergo evaluation by a neurologist specializing in Movement Disorders. PD diagnosis follows the MDS Diagnostic Criteria, supported by the Unified Parkinson's Disease Rating Scale (MDS-UPDRS). The evaluation further includes the RBD Screening Questionnaire (RBDSQ), Montreal Cognitive Assessment (MoCA), and Beck Depression Inventory (BDI-II). Data are entered into RedCap for subsequent statistical analysis. Results are presented as frequencies, percentages, means, and standard deviations. **Results:** To date, 1253 individuals out of a target of 1500, with a mean age of 70.5±7.95 years have been screened between July 2022 and June 2024. Among these screened individuals, 63.6% were female. The prior diagnosis of PD was 1.8%, with 11.7% screened positive for suspected RBD and 34.6% for the Tanner questionnaire. Individuals screened positive for suspected RBD and Tanner, or previously diagnosed with PD, were invited to participate in Phase II. Following the clinical evaluation of 307 patients, preliminary prevalence was estimated at 1.67% for PD, 2.87% for parkinsonism of any cause, and 3.27% for probable/possible RBD. **Conclusion:** Of the individuals diagnosed with PD, 53.85% were male. The result reveal that although the relative proportion of males was lower than that of females, the prevalence of PD diagnoses was higher among males, corroborating existing literature reports. Continued data analysis and detailed clinical evaluations will provide a more precise understanding of the results found in the present study. These findings are crucial for informing and potentially adjusting public health policies in Brazil, aiming to improve early diagnosis and management of these neurodegenerative diseases. On behalf of PROBE-PD

Epidemiology of Alzheimer's disease in Ceará: an analysis of hospitalized patients (2008-2022)

Guilherme Nobre Nogueira[1], Rafaela Fernandes Gonçalves[2], Gustavo Rassier Isolan[2], Gustavo Henrique Tomasi[3], Matheus Roriz-Cruz[4]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.
[2]Faculdade Evangélica Mackenzie do Paraná, Curitiba PR, Brazil.
[3]Universidade do centro oeste do Paraná, Guarapuava PR, Brazil.
[4]Universidade Federal do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Guilherme Nobre Nogueira; Email: guiermenobre@gmail.com.

Background: Alzheimer's disease (AD), as the predominant cause of dementia, constitutes a growing concern in global health. Epidemiology plays a critical role in assessing the burden of AD, providing essential data on its prevalence, incidence, and societal impact. There are well-founded projections indicating that by 2050, the prevalence of dementia will double in Europe and triple worldwide. **Objective:** This study aims to highlight the crucial importance of epidemiology in understanding AD, focusing on the population of the state of Ceará during the period from January 2008 to December 2022, using data from hospitalized patients. **Methods:** This is a retrospective descriptive epidemiological study based on secondary data, using the Epidemiological Information System available in the Notification of Diseases Information System (SINAN), researching AD in the territory of Ceará, evaluating age groups and gender with the number of hospitalizations, deaths, and patient mortality rate from January 2008 to December 2022. **Results:** After a comprehensive analysis of the data related to patients hospitalized for AD in the state of Ceará we obtained the following results: a total of 298 patients were diagnosed with Alzheimer's Disease in the state of Ceará. Of these, 180 (64%) were female, while 118 (36%) were male. Regarding age groups, we observed the following distribution: Age 15-44 years: 28 cases, with 15 (54%) female and 13 (46%) male. No deaths were recorded in this age group. Age 45-59 years: 21 cases, with 12 (57%) male and 9 (43%) female, resulting in one death. Age 60-79 years: 105 cases, with 57 (54%) female and 48 (46%) male, accompanied by 5 deaths. Age 80 years or older: 144 cases, with 45 (31%) male and 99 (69%) female, and 18 deaths recorded in this age group. The chi-square analysis showed a p-value of 0.028 and a Cramer's v-value of 0.175. **Conclusion:** These results indicate a complex distribution of AD in the state of Ceará, with notable variations by gender and age group. They also emphasize the importance of epidemiology in understanding AD and formulating more personalized public healthcare strategies, considering gender and age differences. Furthermore, they underscore the need for further research to investigate risk factors in different demographic groups and the importance of multidisciplinary medical teams in the comprehensive care of AD patients.

Epidemiology of Alzheimer's disease hospitalizations in Brazil: analysis regarding color/race, age group and sex

Maria Alice Pereira Junqueira de Oliveira[1], Matheus Wendell de Almeida Pereira[1], Raissa Jaquelline dos Santos Dias[1], Josué Natã Sampaio Monteiro[1], Peri Bucken Gobbi[1], Ellen dos Santos Brito[1], Gabriel Balbi Fernandes Silva[1], Orlando Dias Canichio[1], Camila de Souza Ferreira[1], Laura Rodrigues Melo[2]

[1]Universidade Federal do Rio de Janeiro, Macaé RJ, Brazil.
[2]Faculdade de Medicina de Petrópolis, Petrópolis RJ, Brazil.

Correspondence: Maria Alice Pereira Junqueira de Oliveira; Email: mariaalice353@gmail.com.

Background: Demographic transition and population aging represent prevalent phenomena in contemporary Brazil. Consequently, there is a need for tailored public health interventions to address the evolving needs of this population group, which is expected to become the majority in the coming years. In light of this, the prevalence of people living with dementia follows this increasing trend, which means that its most common entity, Alzheimer's disease (AD), significantly impacts the daily lives of several individuals as well as the dynamics of health services. **Objective:** To conduct a quantitative analysis of hospitalizations due to AD spanning from January 2014 to January 2024. This analysis aims to juxtapose findings across Brazil's five distinct regions, considering variables such as sex, ethnicity, and age group. **Methods:** This study is an observational, cross-sectional, descriptive, and quantitative analysis conducted utilizing data extracted from the Sistema de Informações Hospitalares do SUS (SIH-SUS), integrated with DATASUS. The investigation

explores variables associated with hospital admissions for AD across the five geographical regions of Brazil, categorized by sex, ethnicity, and age group. The data was collected between March 11th and 22nd, 2024. **Results:** During the analyzed period, a total of 15,445 hospitalizations for AD were documented in Brazil, reflecting an upward trend all over the years. Among the country's five regions, the Southeast region reported the highest caseload, comprising approximately 52.9% of hospitalizations, followed by the South and Northeast regions with 24% and 13.9%, respectively. Women represented the majority of hospitalizations, constituting 65.4% of the total, whereas men accounted for 34.5%. Regarding ethnicity, individuals of Caucasian descent exhibited a predominant presence, representing 48.7% of the total, followed by records with lacking information regarding the variable in question at 23.3% and the "pardo" (brown-skinned) Brazilian race at 22.5%. Regarding age distribution, individuals aged 80 and above constituted the majority of hospitalizations, comprising 58.5% of the total. **Conclusion:** It is noted that 23.3% of recorded hospitalizations lack information regarding the patient's ethnicity, which compromises the development of epidemiological studies as well as the formulation and implementation of public health measures aimed at the effective management of AD. Hence, it is imperative to underscore to various healthcare professionals and administrators the significance of correctly completing records. Furthermore, the prevalence of hospitalizations among individuals aged over 80 underscores the necessity of adequately preparing hospital teams for geriatric care, a facet often overlooked in clinical practice.

https://doi.org/10.5327/CBN240733

Epidemiology of encephalocele in newborns in Brazil: an analysis of the last decade

Michelle Oliveira Teixeira[1], Amanda Mendes Santos[1], Camila Pugliesi de Figueiredo[1], Victor Pedrosa Ferreira de Souza[1], Guaraciara de Andrade Picanço[1]

[1]Universidade Federal de Catalão, Catalão GO, Brazil.

Correspondence: Amanda Mendes Santos; Email: amanda.mendes@discente.ufcat.edu.br.

Background: Encephalocele is defined as the herniation of intracranial contents through an opening in the skullcap due to defects in the closure of the neural tube. Patients may present a variety of symptoms, such as seizures, ataxia, visual deficits, microcephaly and developmental delays. Also noteworthy is the high mortality during pregnancy and after birth. Therefore, it is important to delineate the population with this condition and promote the adoption of prevention measures, such as early folic acid supplementation. **Objective:** To analyze the epidemiological profile of live births with encephalocele in Brazil. **Methods:** This quantitative, descriptive and retrospective study collected data from the Congenital Malformations, Deformities, and Chromosomal Anomalies Monitoring Panel. The variables used were indicator, location, month of pregnancy that started prenatal care, weeks of gestation, type of delivery, APGAR in the 1st and 5th minute and birth weight. The period from 2014 to April 2024 was analyzed, with preliminary data from the last two years. **Results:** During the period studied, a total of 1979 live births with encephalocele were reported, with unspecified encephalocele being the most prevalent (1207). Of the specified encephaloceles, 498 babies were born with occipital encephalocele, 158 with encephalocele of other locations, 107 with frontal encephalocele, and 23 with nasofrontal encephalocele. Dividing by each Brazilian region, 769 cases occurred in the Southeast, 604 in the Northeast, 267 in the South, 181 in the North, and 149 in the Central-West. Regarding prenatal care, the earlier it starts, the better the chances of prevention with folic acid supplementation. That said, 18.2% of pregnant women began in the 1st month, 37.5% in the 2nd, 19.5% in the 3rd, and 17.8% from the 4th month onwards. On the gestational duration, 37.4% were born prematurely. Regarding the delivery type, 21.1% were born vaginally. Regarding APGAR, 59.5% of live births had an APGAR score below 8 in the 1st minute, with 19.5% having severe asphyxia, 13.9% being moderate, and 26.1% having mild. While for the APGAR, at the 5th minute, 38% had a score lower than 8, with 13.9% having severe asphyxia, 6.5% being moderate and 17.7% having mild. About birth weight, 12.7% were born with meager weight, 25.7% were underweight, and 61.5% weighed more than 2500g. **Conclusion:** Although rare, encephaloceles are relevant diagnostic possibilities. A significant percentage of live births with this condition presented perinatal asphyxia, with an APGAR score of less than 8 in the 1st and 5th minute. Prematurity and low weight were also characteristic, although they did not correspond to most cases. As for the late start of prenatal care, its rate was notable, showing that early and universal use of this service is not a reality in Brazil. Therefore, the prevention of neural tube closure defects with folic acid supplementation is still inaccessible for many women.

https://doi.org/10.5327/CBN240734

Epidemiology of multiple sclerosis mortality in Brazil over the last 20 years

émile de Carvalho Morais Fraga[1], érica Otoni Pereira Miranda[1], Guilherme Rocha Cardoso[1], Luídi Neves Nascimento[1], Naila Maria Magalhães da Silva[1], Rebeca Gabrielle Almeida Maciel[2], Emmanuel Santos Trindade[1], Priscila Santos Oliveira[1], Davi Tanajura Costa[1], Philip George Glass Andrade[1]

[2]Universidade Federal da Bahia, Vitória da Conquista BA, Brazil.

Correspondence: Érica Otoni Pereira Miranda; Email: ericaotoni15@gmail.com.

Background: Multiple sclerosis (MS) is the most prevalent demyelinating disease of the central nervous system (CNS). It is estimated to affect between 2 and 2.5 million people globally, with a higher prevalence in females, white individuals and have a peak incidence at the age of 30. Current knowledge of MS mortality in Brazil is limited. **Objective:** To analyze the time trend in MS mortality rate in Brazil between 2001 and 2022, stratified by sex, ethnicity and age group. **Methods:** This ecological time series study assessed the MS mortality rate in Brazil, stratified by sex, ethnicity and age group. Death data was obtained from the Mortality Information System of the Ministry of Health's Department of Informatics of the Unified Health System. Demographic data was obtained from the National Household Sample Surveys and the Continuous National Household Sample Surveys of the Brazilian Institute of Geography and Statistics. Mortality rate trends were analyzed by joinpoint regression. **Results:** 6,848 MS deaths were reported in Brazil between 2001 and 2022. Females accounted for 60.48% of deaths. 66.41% of deaths were of white individuals. 28.8% of deaths occurred in those aged 70 or over. The average annual mortality rate was 0.16 deaths/100,000 inhabitants. Females presented a higher average annual rate (0.19 deaths/100,000 inhabitants) than males (0.13 deaths/100,000 inhabitants). When analyzing the average annual mortality rate by ethnicity, white individuals led the ranking (0.23 deaths/100,000 inhabitants), followed by blacks (0.11 deaths/100,000 inhabitants) and, lastly, browns (0.08 deaths/100,000 inhabitants). The mortality rate is directly proportional to age group, with the population aged 70 years or over having the highest average annual mortality rate (0.93 deaths/100,000 inhabitants), followed by those with 60 to 69 years (0.49 deaths/100,000 inhabitants), 50 to 59 years (0.35 deaths/100,000 inhabitants), 40 to 49 years (0.21 deaths/100,000 inhabitants), 30 to 39 years (0.08 deaths/100,000 inhabitants), 20 to 29 years (0.03 deaths/100,000 inhabitants), and, finally, those under 20 years (0.004 deaths/100,000 inhabitants). It was noticed an overall stationary trend in mortality rate (AAPC: -0.54 [-1.37; 0.29]; p:0.20). Black individuals (AAPC: -1.48 [-2.76; -0.19]; p:0.03), those aged 20 to 29 (AAPC: -3.19 [-6.07; -0.21]; p:0.04) and 70 or over (AAPC: -4.72 [-5.38; -4.05]; p:<0.0001) demonstrated a decreasing trend. Brown individuals (AAPC: 2.26 [0.64; 3.91]; p:0.006) presented an increasing trend. **Conclusion:** This study showed a low mortality rate from MS when compared to countries with a majority Caucasian population. In addition, the data presented corroborates other studies, showing a predominance of Multiple Sclerosis mortality in females, white individuals and elderly individuals in Brazil. The mortality rate trend was stationary.

Epidemiology of patients followed by the post-stroke palliative care team in a reference hospital for stroke treatment in Santa Catarina

Maria Eduarda Angelo de Mendonça Fileti[1], Patrícia Vera[1], Lila Jerusa Nascimento Pereira Abreu[1], Marta Gabriele Pires da Rosa Schmen[1], Camilla Ramos Mohr[1], Jane Rossi[1], Brenner Henrique de Oliveira Marques da Silva[1], Joselma Siqueira de Aquino[1], Carla Heloísa Cabral Moro[1]

[1]Hospital Municipal São José, Joinville SC, Brazil.

Correspondence: Maria Eduarda Angelo de Mendonça Fileti; Email: neuro.mef@gmail.com.

The word palliate derives from the Latin pallium, which means to protect, a form of care, that aims to alleviate pain and suffering. According to the World Health Organization (WHO), in the concept defined in 1990 and updated in 2002, Palliative Care is an "approach that improves the quality of life of patients and their families, who face problems arising from a life-threatening illness, through prevention and relief of suffering, through early identification, impeccable assessment and treatment of pain and other physical, psychosocial and spiritual problems". Studies identified high case fatality after severe stroke, numerous long-term physical problems, substantial emotional distress, prognostic uncertainty, and a sense of abandonment after hospital discharge. Our experience in a reference center for stroke treatment has shown the need of a Post-Stroke Palliative Care Protocol establishment, to support a holistic approach, improving quality of life and ensuring treatment in accordance with the wishes and values of our patients and their families. After the Palliative Care for Post-Stroke Patients Protocol was implemented, a retrospective analysis of the clinical database collected by the electronic medical record was fulfilled. Patients included were those diagnosed with stroke from June 2023 to June 2024 and who received palliative care during the study period. Data from clinical information, medical diagnosis and outcome were collected. Analisis was carried out to obtain the epidemiological profile of patients receiving post-stroke palliative care. 81 patients were followed from June 2023 to June 2024, 31 male patients and 50 female patients, predominantly in the age group of 70 to 89 years. 81% had ischemic stroke and 19% had hemorrhagic stroke. Among the main comorbidities analyzed, approximately: 76% had systemic arterial hypertension, 39% had diabetes mellitus, 7% had dyslipidemia, 3% had a previous stroke and 23% had atrial fibrillation. More than 95% of individuals had multimorbidities. Of these, approximately 33% were previously classified as mRankin level 1 and 32% as mRankin level 3. After the cerebrovascular event, mRankin level 5 predominated, in 75 patients. From the total of 81 patients: 33 patients died, 38 returned home, 9 went to nursing home and one patient still remains in hospital. It is very important to notice that the majority of our patients were discharged from the hospital, counting on our home monitoring program and on the care guidelines provided during hospitalization. Understanding the epidemiology of palliative care after stroke is essential to inform health policies, service planning and clinical practice, aiming to improve the quality of life and health outcomes of these patients.

Epilepsy during the COVID-19 pandemic: an analysis of trends in hospitalizations and deaths in Brazil

Alisson Rafael de Oliveira Pereira[1], José Sidinei Rodrigues Dias[1], Julia de Oliveira Bessegatto[1], Rodrigo Ferreira de Moura[1]

[1]Universidade Federal de Lavras, Lavras MG, Brazil.

Correspondence: Alisson Rafael de Oliveira Pereira; Email: alissonropereira@gmail.com.

Background: From the perspective of public health management, the COVID-19 pandemic between Mar/2020 and May/2023, highlighted the need to overcome operational challenges and implied complications in hospital dynamics, such as instability in bed availability. While the focus was centered on COVID-19, care for other chronic noncommunicable diseases, such as epilepsy, may have been impacted. Thus, to assess the existence of this correlation and create other measures aimed at mitigating these impacts, it is important to understand the behavior of epidemiological data regarding this syndrome. **Objective:** To analyze trends in deaths and hospitalizations due to epilepsy during the COVID-19 pandemic in Brazil. **Methods:** This retrospective study used secondary data recorded at SIH using DATASUS. Data on hospitalizations and deaths due to epilepsy were collected refering to the period May/2019-Mar/2024. The analysis of the time series was performed with joinpoint regression and an ARIMA model to evaluate the influence of the COVID Pandemic as a covariate. **Results:** The regression showed four points of change during the period: Jan/2020, Apr/2020, Aug/2022 and Jan/2023. The initial stationary trend was interrupted by a drop in hospitalizations in Jan/2020, generating a brief downward trend (APC: -8; p=0.1), which was replaced in Apr/2020 by a longer-lasting, linear, and significant upward trend (APC: 1.3; p<0.05). As for Aug/22, a non-significant slight fall regime was established (APC: -0.19; p=0.55), which remained until Jan/23, when there was a new important drop (APC: -27; 95%CI: -32.6 to -18.6; p<0.01). Summarizing the entire period, there was a significant drop in hospitalization for epilepsy (AAPC: -1; 95%CI: -1.2 to -0.7; p<0.01). From deaths point of view, the series presented seasonal characteristics that remained similar to the pattern before the beginning of the COVID pandemic. Although it is not possible to pinpoint this causality to the changes, some of the joinpoints in hospitalizations are related to milestones in the pandemic period, and ARIMA models (0, 0, 0) illustrate the influence of the COVID parameter as a covariate in deaths (B=-0.34; SE=0.1; t=-2.6; p<0.05). The first confirmed case of COVID was registered in Brazil in Feb/2020, although it is likely that the virus was already circulating throughout the country. A decrease in hospitalization may indicate an initial occupancy of beds due to flu-like syndromes. The next elevation may represent the presence of epilepsy-COVID comorbidity. **Conclusion:** Although the ARIMA model demonstrated the influence of the pandemic variable on epilepsy deaths, the previously presented seasonal pattern was maintained. Hospitalization trends initially varied in accordance with milestones and progression of the COVID pandemic in Brazil. Further research is needed to explain the seasonal death pattern and recent trend of a sharp drop in hospitalization.

Background: Epilepsy is one of the most common neurological disorders in childhood, with early implementation of treatment being fundamental for optimizing quality of life and reducing long-term consequences, such as behavioral and learning problems. Therefore, the epidemiological analysis of pediatric epilepsy in the national territory is imperative to guide public health policies that meet the specific demands of each region, thus ensuring adequate access to treatment for all children. **Objective:** To analyze the epidemiology of epilepsy in the pediatric population between 2018 and 2023 in Brazil. **Methods:** This is a descriptive ecological study conducted through data extraction from the Hospital Information System (SIH/SUS), available on DATASUS, in the time series from 2018 to 2023. The variables used were: hospitalizations, total average length of stay, deaths, and epilepsy mortality rate. The covariates used were: sex, age group (0 to 14 years), and region. **Results:** From 2018 to 2013, there were 133,526 pediatric hospitalizations for epilepsy in Brazil, of which 45,018 (33.7%) were recorded in the Southeast, thus being the state with the highest number of hospitalizations. The most affected age group was 5 to 9 years (31,239 cases), corresponding to 23.3% of the total. Regarding sex, there was a predominance of males with 73,901 (55.3%), 24,839 only from the Southeast region. Regarding the total average length of stay, 5.2 days were obtained. However, individually, infants under 1 year old had the highest average (7.3 days), as well as the Northeast region of this same age group had 8.4 days. In 2023, there were 21,256 hospitalizations, equivalent to 15.9% of the total, with a decrease of 2% compared to 2018 (23,942), the year with the highest number of hospitalizations. The total number of deaths was 743, and the highest mortality rate was in the North region, occurring in infants under 1 year old with 1.28%. **Conclusion:** The data collected show that the highest number of epilepsy cases occurred in the Southeast region, in the age group of 5 to 9 years, mainly in males. However, infants under 1 year of age spend more time hospitalized. And although the highest number of hospitalizations is in the Southeast region, the highest epilepsy death rate is in the North region. In view of such data, it is concluded that the formulation of specific public health policies for each region is necessary in order to prevent and minimize the impact and effects of epilepsy on the pediatric population.

Correspondence: Emmanuel Santos Trindade; Email: emmanuelstrindade@gmail.com.

Background: Epilepsy is a condition that causes long-term predisposition to seizures. It is a diverse condition with multiple types and possible syndromes, resulting in variable etiologies and prognoses. Seizures affect approximately 10% of the population, with epilepsy affecting 1 to 2% of the world's population. Individuals with epilepsy have mortality rates 2 to 3 times higher than the general population. Analyzing epilepsy mortality rates is a crucial indicator of the quality of healthcare services. **Objective:** To analyze the mortality rate of epilepsy in Brazil from 2001 to 2022. **Methods:** This is an ecological time-series study of the epilepsy mortality rate in Brazil, stratified by sex, ethnicity and age group. For that, data on deaths from epilepsy were obtained from the Mortality Information System (SIM) and demographic data from the Brazilian Institute of Geography and Statistics (IBGE). The annual mortality rate due to epilepsy was calculated and, subsequently, a temporal analysis was carried out using a joinpoint regression model, through which the Annual Percent Change (APC) and Average Annual Percent Change (AAPC) were obtained with 95% Confidence Interval (95% CI). A value of p<0.05 was considered statistically significant. **Results:** Between 2001 and 2022, 47,437 deaths from epilepsy were reported in Brazil, characterizing an average annual mortality rate of 1.09 deaths per 100,000 inhabitants. The epilepsy mortality showed an increasing trend for the general population (AAPC: 4.67 [4.20; 5.13]; p:<0.01), as well as for males (AAPC: 4.49 [4.02; 4.97]; p:<0.01) and females (AAPC: 5.30 [3.22;7.42]; p:<0.01). The increasing trend was more meaningful in brown (AAPC: 6.52 [5.32; 7.73]; p:<0.01) and white people (AAPC: 5.17 [4.53; 5.81]; p:<0.01) when compared to black individuals (AAPC: 3.36 [1.63; 5.12]; p:<0.01). The age groups with the greatest increasing trend in mortality rate were, in descending order, ≥60 years (AAPC: 6.58 [5.73; 7.44]; p:<0.01), 50-59 years (AAPC: 5.11 [4.23; 6.00]; p:<0.01), < 20 years (3.77 [3.12; 4.42]; p:<0.01); 40-49 years (AAPC: 2.16 [1.50; 2.83]; p:<0.01) and 20-29 years (AAPC: 1.52 [0.88; 2.17]; p:<0.01). The 30-39 age group was the only one to show a stationary trend over the period analyzed (AAPC: 0.64 [-0.27; 1.56]; p:0.17), with an initial decreasing trend from 2001-2016 (APC: -0.89 [-1.60; -0.16]; p:0.02) and subsequent increasing trend from 2016-2022 (APC: 4.56 [1.57; 7.65]; p:<0.01). **Conclusion:** The epilepsy mortality rate in Brazil from 2001 to 2022 presented an increasing trend, regardless of sex. Besides, this trend was higher in brown and white people, as well as in older age groups. This differs from the decreasing trend related in previous national studies. An increasing trend was related in the USA from 1999 to 2017, which may be associated with an increase in all-neurological mortality and in epilepsy prevalence and a change in underlying causes of death.

Epilepsy prevalence as a cause of hospitalization for central nervous system diseases in Brazil: an epidemiological study

Samyra Roberta Assis Souza[1], Ana Luiza Rossetto[1], Luigy Matheus de Freitas Santos[2], João Pedro Diniz Freire[1]

[1]Universidade de Marília, Marília SP, Brazil.
[2]Universidade Federal do Pará, Belém PA, Brazil.

Correspondence: Samyra Roberta Assis Souza; Email: samyraassis@hotmail.com.

Background: The central nervous system, composed of the brain and spinal cord, bears the primary responsibility for controlling and coordinating human bodily activities. However, it is susceptible to various pathologies and conditions that can hinder its functioning. Among these diseases, epilepsy stands out as one of the most widespread and well-known, representing approximately one-fifth (22.2%) of hospitalizations for Nervous System Diseases in Brazil. This chronic neurological disorder manifests as abnormal brain activity, leading to recurrent seizures; despite available treatments, epilepsy presents significant challenges for both patients and healthcare professionals. This summary will briefly discuss some of the disorders

affecting the CNS. Additionally, epidemiological findings related to CNS diseases, as well as epilepsy, will be compared. **Objective:** To compare epidemiological data of diseases affecting the Central Nervous System and Epilepsy. **Methods:** This is a descriptive ecological study concerning the hospitalization rates of patients aged 20 to 59 with epilepsy from February 2022 to February 2024, in relation to all hospitalizations due to central nervous system causes, divided by regions of Brazil. Data extraction was performed from the Hospital Morbidity System of the Unified Health System (SUS), available at the Department of Health Informatics of the Unified Health System (DATASUS). **Results:** In Brazil, 50,001 hospitalizations due to Epilepsy were recorded, accounting for approximately 22.2% of the 224,917 hospitalizations for Diseases of the nervous system. The majority of those hospitalized for CNS Disease were women, representing 56.3%. In contrast, 61.6% of those hospitalized for epilepsy were men. It was also noted that the Southeast region recorded the highest number of cases, with 96,472 (42.8%) for CNS Disease and 21,459 (42.9%) for Epilepsy. However, the second region with the most hospitalizations for CNS disease was the South, with 50,295 (22.3%) of the total, whereas for Epilepsy it was the Northeast region with 11,873 (23.7%) records. **Conclusion:** The study results reveal a gap between findings from different regions, representing social inequalities as well as differences in population size among them. The focus of prevalence lies on the most populous states, such as the Southeast, with the highest number of cases in both comparisons, and the Northeast ranking second in epilepsy cases, although it ranks third when surpassed by the South in nervous system diseases. In light of this information, it is imperative for healthcare professionals to address these conditions, deepening their understanding of risk factors and approaches to epilepsy and nervous system diseases, as well as implementing public policies to prevent and minimize these complications, aiming to ensure a quality life.

Background: Epilepsy is a common disorder of the central nervous system, affecting approximately 1% of the global population. It is a reversible and temporary condition that alters brain function, characterized by motor, sensory, autonomic phenomena, and varying degrees of altered consciousness. Due to its complexity, epilepsy has numerous etiological causes, including metabolic, immunological, infectious, genetic, and unknown factors. **Objective:** This study aims to evaluate the profile of hospitalizations due to epilepsy in Brazil between the years 2019 and 2023. **Methods:** Data collection was conducted using publicly available information from the Hospital Information System of the Brazilian Unified Health System (SIH/SUS) in the Tabnet/DATASUS database between January 15 and May 15, 2024. This study employed a retrospective longitudinal design with a quantitative descriptive approach. Data were grouped by Brazilian macro-regions, type of care, sex, age group, and race/ethnicity. Statistical inference was performed using BioEstat 5.3 software, utilizing paired T-tests for related samples to compare groups, and descriptive statistics, measures of central tendency, and dispersion were used to present the data. **Results:** Between 2019 and 2023, there were 285,241 hospitalizations for epilepsy in Brazil. The majority, 57.90% (n=165,164), were male (p<0.0001), and 45.39% (n=129,468) were of mixed race (p=0.0148). The age group most affected was 1-4 years, accounting for 16.38% (n=46,729; p<0.0001) of the cases. The Southeast region had the highest concentration of cases (n=114,768), corresponding to 40.24% (p=0.0005), with an average annual treatment cost of R$ 42,773,521.85. Mortality was most frequent in the Southeast, with 46.82% (n=3,561) of deaths (p=0.0005) and an average mortality rate of 5.03 (p=0.0013). The number of hospitalizations peaked in 2023, accounting for 22.67% (n=64,650) of the total, compared to only 17.25% (n=49,204) in 2020. The majority of hospitalizations, 93.22% (n=265,915; p<0.0001), were classified as urgent. **Conclusion:** Hospitalizations due to epilepsy are predominantly concentrated in the Southeast region of Brazil, with higher proportions of deaths and treatment costs during the study period. Most cases occurred among male children aged 1-4 years who were of mixed race, with urgent care being the most common type of hospitalization.

Epileptic and developmental encephalopathy secondary to a mutation on gene STXBP1: a case report

Gabrielle Miranda Magalhães Pinto[1], Lourdes Maria Silva de Assis[1], Isabelle Diniz Melo[1], Maria de Fátima Miranda de Oliveira[2], José Lucivan Miranda[3], Fabiane Elpídio de Sá Pinheiro[1], João Joaquim Freitas do Amaral[1], Norma Martins de Menezes Morais[3]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.
[2]Universidade de Fortaleza, Fortaleza CE, Brazil.
[3]Núcleo de Tratamento e Estimulação Precoce, Fortaleza CE, Brazil.

Correspondence: Gabrielle Miranda Magalhães Pinto; Email: gabriellemmp1@hotmail.com.

Case presentation: A 7 year old female patient, born at full-term via vaginal birth with APGAR 7/10. At 4 months, the patient started presenting epileptic spasms, using vigabatrine. She displayed hypotonia and developmental delay (DD). A brain magnetic ressonance, requested for etiological investigation, was normal for her age. The patient evolved persisting with hypotonia and important DD, with poor social interaction, motor stereotypies, hypertonia in the lower limbs, agitared behavior and refractary epileptic seizures. Therefore, an epilepsy genetic panel was requested, resulting in developmental and epileptic encephalopathy-4 (DEE-4) secondary to the pathogenic variant c.364C> T: p.(Arg122Ter), found in heterozygosis on gene STXBP1. She utilized Levetiracetam and Topiramate, but had to interrupt use due to adverse reactions (diskynesias and weight loss). She arrived at our service when she was 4 years old, using valproic acid and clobazam, still presenting daily generalized tonic clonic and atonic seizures. Her eletroencephalogram resulted in polypoint trains and acute waves on central regions durong sleep, eletroclynic compatible to Lennox-Gasteaut Syndrome. Cannabidiol was, in that context, prescribed, resulting in lesaebibg of seizures and clinical improvement, reduce of drowsiness, improvement on development (the patient started sitting without support). She is still unable to speak, make eye contact, comprehend commands, persisting with motor stereotypies, but showing good containment of epileptic seizures. **Discussion:** This case describes a characteristic clinical manifestation of DEE-4, an autossomic dominant disorder caused by a pathogenic de novo variant c.364C> T: p.(Arg122Ter), which generates a premature mRNA stop codon, resulting in loss of function of gene STXBP1. This condition may cause developmental delay (DD), Intelectual disability, movement disorders, autistic characteristics and hyperactive behavior. Furthermore, this encephalopathy is commonly associated with electroclinical syndrones, such as infantile spasms and Lennox-Gastaut, and it's crisis can alter the patient's prognosis according to how it began. Besides, it was reported that 25% of patients have epileptic seizures refractary to anticonvulsivant therapy, making the use of cannabidiol and other alternative therapies. **Final comments:** Therefore, it is necessary for DEE-4 to be more studied by the scientific community, once early diagnosis allows personalized multidisciplinary interventions, contributing for the neuropsychomotor development of the carriers of this mutation. In addition, innovation of therapeutic options is fundamental for advance against the adversities provoked by this condition.

Correspondence: Iago Resende Carvalho; Email: iagorcarvalho42@gmail.com.

Case presentation: A 60-year-old male, with a history of hypertension and deep vein thrombosis, presented with vertigo, paraparesis, and dysarthria for three months. On physical examination he had dysarthria, grade 3 hip flexion (bilaterally) and grade 4 plantar flexion and dorsiflexion of the feet, no sensory deficits, truncal cerebellar ataxia, and more pronounced left-side appendicular dysmetria. Magnetic resonance imaging (MRI) showed nodular masses involving the pons, both peduncles and cerebellar hemispheres, and an expansive lesion in the left cerebellar hemisphere, suggesting metastatic neoplasm. A month later, he was submitted to a craniectomy. Pathological findings showed a dense proliferation of histiocytes with abundant cytoplasm, giant Touton cells, and a moderate lymphocytic infiltrate consistent with Erdheim-Chester disease (ECD). On cytogenetic analysis, BRAF V600 mutation-positive tumor status confirmed. Then, vemurafenib therapy was initiated. On the 6-month follow-up, still in immunotherapy, he maintained dyslalia and left hemiparesis. He eats without assistance but does not deambulate. **Discussion:** We report a case of ECD in a 60-year-old patient with pure neurological signs. ECD is a rare multi-system non-Langerhan cell clonal histiocytosis, with less than 1000 reported cases, that may affect the CNS. The mean age of diagnosis is 57 years with a male prevalence. Its etiology involves activation of the mitogen-activated kinase pathway, leading to tissular accumulation of histiocytes. It is clinically heterogeneous, with bone pain in distal extremities in almost all cases. The most common neurological manifestations are cerebellar and pyramidal syndromes and even though those present in almost 41% of the patients, pure neurological disease is rare, with 39 cases reported. At MRI, the lesions are T2-hyperintense masses affecting mostly the pons, and cerebellum. Classic histological features are foamy histiocytes, multinucleated giant cells, and Touton giant cells. Immunohistochemical staining is positive for CD68 and negative for CD1a. The gold standard for diagnosis is the detection of any MAPK pathway alterations, especially BRAF mutation, that was present in our patient, the treatment for which is BRAF-inhibitors such as vemurafenib. It is important to consider other histiocytic disorders, solid

metastatic tumors, or primary central nervous system tumors in the differential diagnosis. In our case, the MRI suggested metastatic lesions, which were later proven a manifestation of the ECD. The prognosis is poor, as there is no known cure, and neurological involvement worsens its outcome. **Final comments:** ECD is a rare disease that may have only CNS symptoms, which greatly increases mortality. In patients with new-onset cerebellar and pyramidal syndromes with masses in imaging with unclear etiology, ECD should be considered as a differential diagnosis. Correlation of clinical features, histology, and radiological findings is essential.

Background: Erenumab is a fully human monoclonal antibody that targets the calcitonin gene-related peptide (CGRP) that blocks selectively the CGRP receptor, a neuropeptide that plays a critical role in the pathophysiology of migraine. CGRP levels contribute to the transmission of pain signals, being elevated during migraine attacks. Targeting this pathway, erenumab reduces the frequency and severity of migraine episodes. However, as a novel treatment, erenumab safety and efficacy is still unclear. **Objective:** Assess the safety and efficacy of Erenumab in different dosages for patients with migraine through the analysis of reduction in Monthly Migraine Days and the intensity of symptoms by the analysis of the Headache Impact Test (HIT-6) and Migraine Physical function impact diary(MPFID) tests. **Methods:** A thorough literature search was conducted across PubMed, Scopus, and the Cochrane databases, focusing on randomized controlled trials comparing the efficacy and safety of Erenumab with a placebo. Mean differences were employed to evaluate the endpoints with 95% confidence intervals (CI) estimated through a random-effects model. We used I^2 statistics to evaluate heterogeneity. All statistical analyses were performed using the R statistical software (version 4.3.2). **Results:** We included 11 studies involving 4784 patients, of whom 2743 (57.33%) received Erenumab. The follow-up period ranged from 4 to 26 weeks. Compared with the placebo, there was a statistically significant difference between groups tending for erenumab in reducing Monthly Migraine Days (MD -1.64; 95% CI -1.90;-1.39; p<0.000001; I^2=25%), which was also demonstrated with the HIT-6 (MD -2.18; 95% CI (-2.61;-1.75); p<0.000001; I^2=0%). In the analysis of MPFID, there was an also statistical significance favoring Erenumab therapy, associated with the reduction of Migraine Physical Function Impact Diary- Everyday Activities (MPFID-EA) (MD -2.4; 95% CI (-3.59;-1.22); p=0.000071; I^2=90%) outcomes. **Conclusion:** This meta-analysis underscores the effectiveness of Erenumab in reducing Monthly migraine days and decreasing the intensity by reducing the HIT-6 and MPFID scores. Furthermore, the safety of the medication has been proven by analyzing the Relative Risk (RR) of the side effects. Some mentioned effects were Constipation with 95 from 2534 (3.74%) in the intervention and 38 from 2842 (1.33%) in the placebo group (RR 2.58; 95% CI (1.76; 3.77); p=0.000001; I^2=0%) favoring the placebo. But also, Fatigue with 31 from 1519 (2.02%) in the intervention and 27 from 1768 (1.52%) in the placebo group (RR 1.22; 95% CI (0.73; 2.03); p=0.454686; I^2=0%) and Nasopharyngitis with 205 from 2440 (8.4%) in the intervention and 243 from 4000 (6.07%) in the placebo group (RR 0.99; 95% CI (0.55; 1.77); p=0.975082; I^2=92%) but without statistical significance.

Erenumab for treatment of episodic migraine with previous treatment failures: a systematic review and meta-analysis

Caio Luiz Nazar Cunha[1], Lucas Kenzo Ozera[1], Ana Clara Nogueira Cezar[1], Eduarda Lemos Gonzaga[1], Laura Caroline Felipe de Freitas[1], Lucas Figueira Vieira[1], Felipe Araujo Gouhie[1], Diogo Fernandes dos Santos[1]

[1]Universidade Federal de Uberlândia, Uberlândia MG, Brazil.

Correspondence: Caio Luiz Nazar Cunha; Email: caiolnc@hotmail.com.

Background: Enumab is a fully human monoclonal antibody, whose use has emerged as an alternative for the preventive treatment of episodic migraine. However, the effects and outcomes of Erenumab use for this purpose still need to be clearly understood. **Objective:** To evaluate the efficacy of Erenumab treatment compared to placebo in adult patients with episodic migraine who have previously failed preventive treatment by analyzing randomized clinical trials. **Methods:** A comprehensive systematic review using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) was conducted to evaluate the efficacy of Erenumab in adults with episodic migraine and a history of treatment failures. The analyzed outcome was the percentage of patients with at least > 50% reduction in Monthly Migraine Days (MMD). The search was conducted in the following databases: PubMed, Embase, and Cochrane. Statistical analysis was performed using R studio 4.3.1, and study heterogeneity was assessed using the I^2 index. **Results:** Four randomized clinical trials were analyzed, encompassing 2,693 patients with episodic migraine who had failed previous treatments. Erenumab was the treatment strategy for 1445 patients. Dosage of 70mg (OR 2.12; 95% CI; 1.16 - 3.87; p=0.03; I^2=80%) and 140mg (OR 3.57; 95% CI; 2.00 - 6.36; p=0.12; I^2=58%) was analyzed. A statistically significant symptomatic improvement was detected, favoring patients in the Erenumab group (OR 3.20; 95% CI; 1.96 - 5.24; p<0.01; I^2=87%). **Conclusion:** The analysis of four randomized clinical trials involving 2,693 patients revealed a statistically significant improvement in migraine symptoms among those treated with Erenumab compared to placebo. These findings suggest that Erenumab offers a promising option for patients with episodic migraine, opening up new possibilities for those who have not benefited from conventional preventive therapies.

Escobar syndrome associated with arthrogryposis multiplex congenita: a rare case presentation

Gabriela Moraes Azevedo[1], Laís Brandão Mota[1], Cleo Alcantara Fernandes Silva[1], Camilla Rocha Medeiros Pinho[1], Rafael Amaral de Matos Albuquerque[1], Guíniver Couto Almeida[1], Gabriel Negreiros de Camargo Martins Moreira[1], Luna Souza Silva Vilanova[1], Marilaine de Matos Menezes Ferreira[1], Marcela Câmara Machado Costa[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Laís Brandão Mota; Email: bmota.lais@gmail.com.

Case presentation: A 17-year-old female patient diagnosed with Escobar syndrome associated with arthrogryposis multiplex congenita (AMC) at birth attended a neurological clinic presenting pterygium and myopathy in both upper and lower limbs, associated with hypotrophy and muscle strength graded at +/IV. She uses long orthoses and specific shoes, since a scanometry identified a 12 cm asymmetry in the lower limbs, with the left femur being longer. Her osteotendinous reflexes are grade 2 in the upper limbs, but patellar reflexes were not obtained due to knee arthrodesis. The patient has undergone previous surgeries for clubfoot correction and an unspecified knee surgery, resulting in a lack of flexibility at 180°. Additionally, she experiences difficulty extending the second distal quadrant bilaterally, with ulnar deviation of the fingers and a single transverse palmar crease. The patient presents an S-shaped scoliosis and rapidly progressing lumbar hyperlordosis, scheduled for surgical correction. Tongue atrophy and fasciculations, along with alterations in the lips, buccinator, soft palate, and a short, winged neck, were observed. She reports a hypernasal and hoarse voice, reduced loudness, pneumophonoarticulatory incoordination and dysphagia, requiring her to crush pills before ingestion. Patient is underweight (BMI: 13.88 kg/m^2). She undergoes irregular lung expansion therapy with a bag valve mask and uses Bilevel Positive Airway Pressure (BiPAP) at night, but shows progressive deterioration of respiratory function, with reduced vital capacity (950mL) and forced vital capacity (750mL). Laboratory tests reveal decreased creatinine (0.4mg/dL), elevated mean corpuscular hemoglobin concentration (33.7g/dL), and increased red cell distribution width (13.5%). Patient is being monitored by an orthopedist, pulmonologist, and motor/respiratory physiotherapist. She also had a first-degree cousin who died with a similar condition. **Discussion:** This case describes a patient with rare diseases: Escobar syndrome, a genetic and attenuated form of multiple pterygium syndrome, and AMC, characterized by joint contractures at birth. The diagnosis was confirmed by medical history, physical examination and additional tests. The negative progression of respiratory function and spinal deformities is a classic manifestation of the diseases, impairing mobility and quality of life, especially with irregular adherence to physiotherapeutic treatment. The rarity of these conditions underscores the importance of family genetic counseling. **Final comments:** Managing rare diseases such as Escobar syndrome and AMC emphasizes the crucial need of a multidisciplinary approach to ensure comprehensive care for the patient. The progression of complications is the primary challenge, as there is no definitive cure, only palliative treatments. Further research is essential to expand knowledge about these diseases, aiming to improve the prognosis and quality of life for the patient.

Etiological profile and outcome of people with optic neuritis treated at a neurological clinic between 2005 and 2022 in the interior of the Brazilian Amazon

Marcos Manoel Honorato[1], Savio Fernandes Soares[1], Lucas Silva Maia[1], Fernanda Lira Duarte[1], Frank Josué Costa Do Nascimento[1], Ana Karoline Pereira Camarão[1], Kelson Vinicius Dallabrida Padilha[1], Samuel Oliveira de Amorim[1], Bernardo Barbosa Penalber[1], Átila Barros Magalhães[1]

[1]Universidade do Estado do Pará, Santarém PA, Brazil.

Correspondence: Marcos Manoel Honorato; Email: marcos.honorato.dr@gmail.com.

Background: Optic Neuritis (ON) includes any inflammation involving the optic nerve and it is closely related to nerve demyelinating processes, typically idiopathic, when not associated with Multiple Sclerosis (MS) or Neuromyelitis Optica (NMO). Viral infections can also be implicated. Estimated annual incidence of new-onset ON ranges from 0.56 to 5.1 cases per 100,000 person-years. The presentation of ON can be typical (unilateral visual loss, subacutely, with ocular pain and mild disc edema) or atypical. Severe visual loss (loss of light perception), optic disc or retinal hemorrhages, significant edema, uveitis or exudates and bilateral involvement is considered atypical. **Objective:** Characterize the etiological profile and treatment response of individuals with Optic Neuritis treated at a private clinic in the Amazon from 2005 to 2022. **Methods:** This retrospective, descriptive, cross-sectional study employed a quantitative approach to analyze data from 32 individuals diagnosed with Optic Neuritis and treated at a neurological clinic from 2005 to 2022. It examined sociodemographic and clinical characteristics, complementary tests, definitive diagnoses, treatments, and therapeutic responses. Fisher's exact test was used to assess the correlation between categorical variables and clinical improvement of Optic Neuritis. **Results:** Females accounted for 71.88% of the sample. Among the patients treated, the mean age at diagnosis was 30.62 years, ranging from ± 11.23 years. As to etiologies, idiopathic cases accounted for 56.25%, followed by multiple sclerosis (18.75%), neuromyelitis optica (12.50%) and collagenosis (12.50%). Among the clinical aspects, bilateral visual symptoms were identified in 46.88% of the cases, ocular pain in 37.50%, in addition to motor and/or sensory alterations related to the underlying disease (78.14%), with a predominance of hemiparesis (21.88%). Neuroimaging showed abnormalities in 71.88%, with optic nerve abnormalities in 21.88%. Abnormal cerebrospinal fluid corresponded to 34.88%, the mean number of cells found was 8.37±33.23 and the mean number of proteins was 49.18±57.24, with an increase in gamma globulin of 21.88%. Anti-aquaporin 4 antibody was positive in 3.13%. Therapy occurred in 78.13%, interventions such as pulse therapy within one month of symptom onset (56.25%), isolated use of oral corticosteroids (34.38%) and use of immunoglobulin were adopted. The outcome revealed partial improvement after medication (81.25%) and, to a lesser extent, complete recovery after its use (12.5%). Pulse therapy was effective in 88% of cases, while 80% of those who used oral corticosteroids alone improved. **Conclusion:** Although no statistical correlation or predictors of a more favorable prognosis were identified, a significant improvement in optic neuritis was observed in patients undergoing some type of treatment. This discrepancy can be attributed to the small sample size.

Evaluating the impact of mechanical thrombectomy availability on ischemic stroke outcomes in Brazil's public health system

Victoria Cavalcanti de Souza[1], Alice Volpato Rocha[1], Ester Namie Hanai[1], Laura Louise Marques Nobrega Vieira[1], Gabriel Volpato Rocha[1], Viviane de Hiroki Flumignan Zétola[1]

[1]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Victoria Cavalcanti de Souza; Email: victoriacavalcantisouza@gmail.com.

Background: Mechanical thrombectomy increases by three times the likelihood of a patient with acute ischemic stroke, caused by the occlusion of a large cerebral artery, achieving functional independence and avoiding major sequelae if performed within 8 hours after the onset of symptoms. Additionally, the recanalization rate after thrombolysis is 30% in patients with proximal middle cerebral artery occlusion and less than 10% in those with carotid artery occlusion. However, in many public healthcare services in Brazil (SUS), thrombolytic therapy is still more frequently used over thrombectomy, and in most cases, thrombectomy is not an available option. **Objective:** To assess the number of patients who could benefit from mechanical thrombectomy if it were widely available in the Brazilian public healthcare system (SUS). **Methods:** This is an observational and retrospective study, in which patients referred to the Stroke Protocol via local emergency medical services (SAMU) to a referral hospital in Curitiba from January 2023 to May 2024 were analyzed. Data regarding the time of stroke onset, arrival at the hospital, and adherence to DEFUSE-3 criteria were collected through active search in the medical records. **Results:** The medical records of 176 patients who arrived at the referral hospital through the Stroke Protocol via (SAMU) and were diagnosed with ischemic stroke were reviewed. Of these, only 56 (31.8%) underwent thrombolysis, and 44 (25%) patients had a time interval of six to twenty-four hours from the event onset to hospital arrival, making them potentially eligible for mechanical thrombectomy. **Conclusion:** Although mechanical thrombectomy is now available in the Brazilian Unified Health System (SUS), only 12 hospitals are equipped to perform it, with only one in the Northeast region (Hospital Geral de Fortaleza (CE)). Ischemic stroke patients within a six to twenty-four-hour time interval from stroke onset who underwent mechanical thrombectomy in addition to clinical treatment had greater functional independence compared to those who received only clinical treatment. Moreover, there is evidence that mechanical thrombectomy significantly increases the success rate of vessel recanalization and reduces the risk of neurological injury relative to clinical treatment alone.

Correspondence: Juliana Cerqueira Gomes; Email: juligomesc5@gmail.com.

Cerebral infarction is a condition that interrupts the blood flux from the brain generated by thrombus, emboli or other elements. Chemical thrombolysis is one of the therapeutics used in the acute phase of the disease when the patient has indication and is on the time window. Evaluate and compare Brazil's regions with factors linked to hospitalizations from cerebral infarction and number of chemical thrombolysis done to treat them in 2014-2023. It's a temporal series ecological study with data from the Hospitalar Information System linked to the Informatics Department of the Unified Health System along an analysis of the number of Hospitalar internment authorizations, mean of the length of stay, deaths and in-hospital mortality rate for cerebral infarction and the number of thrombolysis used to treat this condition, ICD10 code 0303040300, in the period of 2014 and 2023. The data was tabulated in Excel 2023 with calculation of dispersion and central tendency measures. The statistical analysis happened with the BioEstat v5.3 software, adopting p<0.05 as meaningful. In the period, there were 209,377 (20,938±2,780) hospitalizations in Brazil, with the Southeast presenting 45% of them and possessing the biggest mean (9,473±1,943) (p<0.05). Furthermore, there were differences between the mean of all regions except amidst the North and the Central-West (p<0.05). The mean of the length of stay in days had a lower median in the South (7.9±0.3) being similar to the Northeast (8.1±0.5) with statistical difference with all other clusters (p<0.05). There were a total of 31,865 deaths in Brazil (Mean: 3,186±407) with 50% of them in the Southeast (Mean: 1,599±363) that presented the biggest mean of all regions (p<0.05). The mean of the in-hospital mortality rate was higher in the North (17.5±3.2) with statistical difference with the Northeast (14.5±1.7) and the Central-West (14.1±2.2) (p<0.05). The South had the lowest median of the in-hospital mortality rate (12.6±0.8) with a difference happening when paired with the North (17.57±4.88) and Southeast (16.7±1.45) (p<0.05). There were a total of 31,405 thrombolysis done in Brazil (Mean: 3,140±1,572) with the Northeast responsible for 35% (1,013±611), the South for 30% (946±285) and the Southeast for 29% (922±578) with a difference of means happening with these regions and the Central-West (168±140) (p<005), but without differences between them. The North had 18 procedures done (Median: 0±0.25) with statistical difference with all the regions except the Central-West (168±140) (p<0.05). The majority of deaths and hospitalizations happened in the Southeast. The North had the highest in-hospital mortality rate and the lowest number of thrombolysis done meanwhile the Northeast and South had the majority of thrombolysis done and had the lower mortality rates. This could show regional disparities in the follow-up and investment destined to this condition.

Evaluation and differentiation of edema and tumor infiltration in patients with high-grade glioma: initial experience using T2 relaxometry tests

Letícia Mansano de Souza[1], Sérgio Lourenço Polo Filho[1], Brunno Machado de Campos[1], Thiago Magalhães de Souza[1], Cleiton Formentin[1], Marcus Vinicius Giglio[1], Fernando Cendes[1], Enrico Ghizoni[1]

Correspondence: Sérgio Lourenço Polo Filho; Email: s205772@dac.unicamp.br.

The differentiation between edema and tumor infiltration in high-grade gliomas is fundamental for surgical planning. However, this distinction is challenging using conventional magnetic resonance imaging (MRI). New advanced magnetic resonance imaging (MRI) techniques are capable of inferring tissue composition, potentially contributing to such differentiation. In this study, we used magnetic resonance images in multi-echoT2 sequence (RMT2m) processed using a quantitative technique known as relaxometry to differentiate between edema and tumor infiltration in high-grade gliomas. In this study, we report our initial experience using multi-echoT2 relaxometry to differentiate perilesional edema from tumor infiltration in patients with high-grade gliomas. Patients who underwent RMT2m and with an anatomopathological diagnosis of brain tumor were retrospectively selected, divided into two groups: metastasis/meningiomas, in which it is assumed from the literature that hyperintensity in RMT2m corresponds to vasogenic edema, and high-grade gliomas, where there are present both edema and tissue infiltrated by tumor cells. The areas of hyperintensity in RMT2m were manually delimited in both groups and analyzed using the Relaxo-LNI software, developed in-house. In the group with high-grade gliomas, this analysis was subdivided into regions of interest in the center (close to the capturing lesion) and in the periphery of the tumors (far from the capturing lesion). Ten patients were

included in the group with metastases/meningiomas and twenty patients in the group with high-grade gliomas. The mean relaxation times in RMT2m were higher for the high-grade glioma group when compared to the control group (p<0.05). The relaxometry times were also longer means of relaxation of central areas of high-grade gliomas (mean value of 498.68), where tumor infiltration is the most common component, in relation to peripheral areas (mean value of 136.13), p<0.05, where edema tends to be predominant. The mean T2 relaxometry value in the periphery of the glioma was significantly closer to the T2 values observed in patients with meningiomas and metastases, which have a mean value of 196.8, p< 0.05. This proximity in values suggests that areas peripheral to the glioma exhibit characteristics that are more similar to edema than to tumor infiltration difference was statistically significant (p<0.05). Statistical results suggest that the RMT2m relaxation times' analysis - in this study using the Relaxo-LNI software - could be helpful to differentiate edema and tumor infiltration in patients with high-grade gliomas, allowing for a more efficient preoperative planning and postoperative assessment of tumor infiltration resection rate. Next steps include determining cut-off values for relaxation time where it is safe to assert the absence of tissue infiltrated by tumor cells, contributing to pre-operative planning and post-operative assessment of the extent of resection of these lesions.

Evaluation of atypical festinating gait in a patient with Wilson's disease

Pedro Henrique Ximenes Ramalho Barros[1], Ocílio de Deus da Rocha Ribeiro Gonçalves[1], Celli Veloso Cavalcanti[1], Kayron Rodrigues Lima[1], Jonas Leite de Souza Filho[1], Gustavo Viana Castro[1], Luma Rodrigues da Silva[1], Dário Correia Negreiros[1], Tiago José Do Nascimento Teixeira Leite[1], Kelson James Almeida[1]

[1]Universidade Federal do Piauí, Teresina PI, Brazil.

Correspondence: Pedro Henrique Ximenes Ramalho Barros; Email: pedrohx587@gmail.com.

Case presentation: A 35-year-old man, diagnosed with Wilson's disease (WD) for 9 years, was admitted with reports of insomnia, affective lability with pseudobulbar humor and irritability, hypotimia, negativism, anticipatory suffering, self-referential and death thoughts, low self-esteem, persecutory delusions, and challenging behavior, which started 8 months ago with progressive worsening. On physical examination, he presented choreiform facial movements, bilateral resting tremor, generalized muscular dystonia, hardness in gait, inability to stand without support, and limited to the wheelchair. During the dynamic gait, the patient had a festinating gait with Bobbing characteristics and was unstable with predominate freezing of gait in all the states of the gait. The patient's speech and swallowing are impaired. Escitalopram 10mg/day was started without improvement, which was then replaced by Mirtazapine 30mg/day and Quetiapine 25mg/day, with slight mood improvement, reduced irritability, and delusions after 20 days of use. He discontinued the chelation therapy for WD 5 years ago. During the same period, he began continuous abuse of alcoholic beverages. The use of other psychotropic drugs was not reported. Currently, he refuses psychotropic medication, using only the chelator, thus maintaining agitation, impulsivity, and challenging behavior. **Discussion:** WD is a genetic condition affecting the ATP7B gene, essential for the transport and subsequent biliary excretion of copper. A defect in this pathway leads to a progressive accumulation of copper in the body, especially in the liver. Additionally, the metal can deposit in other tissues, causing a variety of symptoms, such as dysarthria, ataxia, dystonia, tremors, parkinsonism, and Kayser-Fleischer. The patient's physical evaluation presented a rare finding: the presence of a festinating, exhausting, and bobbing gait (more related to severe atypical parkinsonism). It was characterized by the progressive shortening of step length, a compensatory increase in cadence, and difficulty in postural control. **Final comments:** Early diagnosis is common, making treatment essential in controlling the progression of the disease. Thus, this report expresses atypical characteristics of WD, especially festinating gait, and the implications of discontinuing specific therapy. That WD can exhibit different patterns of presentation, reflecting the challenge of establishing an early diagnosis. Is probable that gait findings are due to chronic ineffective that prevents the onset of the first symptoms.

Evaluation of benign multiple sclerosis beyond the EDSS: cognitive, fatigue and mood disorders

Josué de Almeida David[1], Thomas Vieira de Paula[1], Alfredo Damasceno[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Josué de Almeida David; Email: j219131@dac.unicamp.br.

Objective: This study aims to analyze cognitive and clinical aspects of patients with benign MS (BMS) to gain a deeper understanding of this condition. **Methods:** Sixty patients from a tertiary MS service were included in the study, with 30 individuals exhibiting an Expanded Disability Status Scale (EDSS) score below 3.0 and a minimum of 10 years since disease onset. Participants underwent cognitive evaluations as well as assessments for mood disorders, fatigue, and motor dysfunction. More stringent criteria for BMS were also tested. **Results:** Most patients identified as having BMS in this cohort were female, with a mean EDSS score of 1.9 and good performance on both the Timed 25-Foot Walk (5.2 sec) and Nine-Hole Peg Test (23.2 sec) motor assessments. Cognitive deficits were more prevalent in traditional MS patients compared to those classified as having BMS. The frequency of depression was similar between the two groups. Moreover, employing stricter criteria for classification did not yield superior clinical or cognitive outcomes. **Conclusion:** This study reinforces previous epidemiological findings observed in other countries within the context of the Brazilian population. Additionally, it highlights the prevalence of non-motor symptoms and cognitive impairment in both traditional MS and BMS. These findings underscore the need for a distinct approach when evaluating and classifying BMS patients.

https://doi.org/10.5327/CBN240752

Evaluation of brain morphometry by magnetic resonance imaging in patients with psychogenic nonepileptic seizures

Fernando Cendes[1], Lucas Gabriel Alves Figueiredo[1], Luciana Ramalho Pimentel[1], Clarissa Lin Yasuda[1], Brunno Machado de Campos[1], Marina Koutsodontis Machado Alvim[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Lucas Gabriel Alves Figueiredo; Email: l201917@dac.unicamp.br.

Background: Psychogenic nonepileptic seizures (PNES) are episodes of alterations in consciousness and subjective experience accompanied by self-control impairment. Due to their similarity, patients with this condition are often misdiagnosed and treated as if they had epilepsy. A possible tool for better understanding PNES is neuroimaging. However, there are few such studies, and the information in the literature is inconclusive. **Objective:** Evaluate magnetic resonance imaging (MRI) morphometry - cortical thickness, cortical surface area, curvature, and volume of subcortical structures - in patients with PNES, mesial temporal lobe epilepsy (MTLE), and controls. **Methods:** 163 participants were divided into three groups: PNES (with or without epilepsy, n=40), MTLE only (n=54), and a control group (n=69). Image processing was performed using Freesurfer 6.0 software. Differences between groups means were evaluated with generalized linear models, including age as a covariate. Correction for multiple comparisons was performed using FDR and Sidak. **Results:** Regarding volume, 8 structures in the PNES group were larger (P<0.046) than in MTLE, including the corpus callosum, left hippocampus and left cerebellar cortex. The volume of 7 structures was smaller (P<0.041) in PNES compared to controls (bilateral thalami, nucleus accumbens, and total gray matter), and 30 structures were different (P<0.01) between MTLE x control, with the vast majority being smaller in MTLE as expected. Regarding curvature, the left entorhinal cortex was smaller (P=0.019) in PNES than in MTLE. However, curvature was increased in 13 structures (P<0.03) in PNES and 15 structures (P<0.03) in MTLE compared to controls. Additionally, the right rostral anterior cingulate cortex was thinner (P=0.011) in the PNES group than in MTLE, but there was no significant difference between PNES versus controls and MTLE versus controls. Thickness was also smaller in 17 structures (P<0.03) in PNES and 12 structures (P<0.035) in MTLE compared to controls. **Conclusion:** The regions with the differences between the groups identified are fundamental for cognitive, emotional, behavioral, and executive control. These morphometric differences may contribute to a better understanding of PNES and to defining biomarkers for differentiating PNES and epilepsy. However, further studies are needed to draw better conclusions.

https://doi.org/10.5327/CBN240753

Evaluation of cerebello-cortical pathways using the virtual brain in a patient with cerebellar mutism: study methodology

Thalles Olivi de Almeida[1], Jose Reynaldo Walther de Almeida[2] , Brigida S Oliveira[1], Ana Carolina Campos[1], Marcos Vinicius Calfat Maldaun[1]

[1]Hospital Sírio-Libanes, São Paulo SP, Brazil. [2]Intituto de Neurociencias de Araraquara e de Barretos.

Correspondence: Thalles Olivi de Almeida; Email: almeida.thalles@outlook.com.

Background: Cerebellar mutism or posterior fossa syndrome (PFS) is a rare occurrence in adult patients undergoing surgery for cerebellar tumors. Brigida S Oliveira recently showed that tractography has limited utility in predicting PFS in children. Palesi et al. used The Virtual Brain (TVB) to evaluate whether the inclusion of cerebellar connectivities is important for simulating brain dynamics in healthy individuals. We evaluated an adult patient who underwent resection of a left cerebellar metastasis and developed severe posterior fossa syndrome immediately postoperatively. She underwent MRI with DTI and EEG with nonlinear analysis of the time series. **Objective:** To study the pathways: 1- cerebellum-thalamus-basal nuclei-cortex: primary motor cortex (1-M1), premotor cortex (1-PMC), supplementary motor area (SMA) and 2- cerebellum-thalamus-basal nuclei-cortex: dorsolateral prefrontal cortex (2-PFC), orbitofrontal cortex (2-OFC), using TVB and nonlinear metrics. **Methods:** After preprocessing the T1 and DTI data, the TVB avatar was generated using the Glasser atlas with 180 cortical regions and 17 subcortical regions. Empirical EEG from 19 channels generated the functional connectivities. We used the Jansen-Rit model in TVB. The

model parameters were adjusted according to the literature. The described networks were isolated and compared between hemispheres using mean mutual entropy and the relationship MPR-complexity x permutation entropy, global and local efficiency. **Results:** GLOBAL/LOCAL EFFICIENCY: 1-M1 right = 0.36 / 0.31 and left = 0.21 / 0.15. 1-PMC right = 0.35 / 0.36 and left = 0.23 / 0.21. 1-SMA right = 0.36 / 0.30 and left = 0.20 / 0.18. 2-PFC right = 0.39 / 0.32 and left = 0.19 / 0.12. 2-OFC right = 0.33 / 0.29 and left = 0.19 / 0.19. MEAN MUTUAL ENTROPY: 1-M1 right = 0.25 and left = 0.15. 1-PMC right = 0.28 and left = 0.09. 1-SMA right = 0.45 and left = 0.14. 2-PFC right = 0.39 and left = 0.09. 2-OFC right = 0.33 and left = 0.16. MPR COMPLEXITY / PERMUTATION ENTROPY MEAN: 1-M1 right = 0.254 and left = 0.219. 1-PMC right = 0.247 and left = 0.217. 1-SMA right = 0.244 and left = 0.225. 2-PFC right = 0.247 and left = 0.226. 2-OFC right = 0.234 and left = 0.225. **Conclusion:** The analyses showed interesting differences, with the left networks severely compromised, and suggest that TVB can be a useful tool in evaluating cerebello-cortical networks, with potential for clinical use in the future.

Evaluation of cognitive impairment in long-severe COVID patients

Leidys Marina Pedrozo García[1], Marciéli Gerhardt[2], Fabio Jean Varella de Oliveira[1], William Alves Martins[2], Eduardo Leal Conceição[2], Helena Scartassini Erwig[1], Larissa Frozza Fernandes[1], Helena Morsch Marques[1], Francine Nunes Pereira[1], Jaderson Costa da Costa[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.
[2]Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Marciéli Gerhardt; Email: marcieligerhardt@yahoo.com.br.

Background: "Long Covid" is an expression for describing the syndrome with signs and symptoms that emerge or continue after a Covid-19 acute infection. These symptoms must persist for over 12 weeks and are not explained by an alternative diagnosis. Persistent symptoms include breathing difficulty, fatigue, mental health disorders and cognitive impairment. **Objective:** To measure and characterize the cognitive impairment and psychiatric disorders related to Covid-19 infection. **Methods:** This is a cross-sectional study, approved by our institution's ethics committee (CEP:6.123.125), in a population-based cohort. Two hundred patients admitted to the ICU of a hospital in Porto Alegre due to severe Covid-19 infection and who were discharged from 01/15/2021 to 03/30/2021 were assessed for eligibility. Data regarding cognitive function (Montreal Cognitive Assessment [MoCA] and Addenbrooke's Cognitive Examination [ACE-III]), psychiatric comorbidities (Hamilton scales) and quality of life (Short Form Health Survey [SF-36]) were collected. **Results:** A total of 46 patients were enrolled, regardless of their cognitive status, with an average age of 52.2 years (DP 12.1). Twenty-four (54,3%) were male. The vast majority (95.6%) was not experiencing social isolation and had at least eleven years of education (91.3%). We found that many patients suffered from executive and visuospatial dysfunction, performing similarly in MoCA and ACE-III, with a median score of 3.87 (maximum score of 5; DP 1.29; P=0.099) and 14 (maximum score of 16; DP 1.08), respectively. Language was also impaired in our patients, with average scores of 2.52 (maximum score of 3; DP 0.72; P=0.380) and 24.82 (maximum score of 26; DP 1.82) in MoCa and ACE-III, respectively. Regarding memory, MoCA had an average score of 2.7 (maximum score of 5; DP 1.48), while ACE-III showed a score of 18.7 (maximum score of 26; DP 1.5). Unexpectedly, memory performance in both tests was significantly worse even in patients with more than 14 years of formal education. Of all patients, 30,5% (n=14) had normal cognition, 13.04% (n=6) had physical deficit without cognitive impairment, 34.78% (n=16) had mild cognitive impairment (MCI) and 21.73% (n=10) had dementia. The median scores in MoCA were 27.36 (DP±1,216), 27.67 (DP±0,816), 22.75 (DP±2,543) and 22.30 (DP±3,129) in each group, respectively. The median scores in ACE-III were 87.79 (DP±5,820), 92.33 (DP±5,502), 83.81 (DP±8,101) and 80.2 (DP±7,642), respectively. **Conclusion:** This study provides evidence for a protracted cognitive impairment years after severe Covid-19 infection, showing a combination of executive, visuospatial, language and memory impairments. Although other factors, such as prolonged ICU stay, may have had a role, our findings support that even relatively heathy patients suffer from Covid-19 cognitive dysfunction, which was displayed even more prominently in highly educated patients.

Meningitis, an inflammation of the meninges surrounding the Central Nervous System (CNS), can be of viral, bacterial, fungal, or parasitic origin, with the bacterial form being the most severe, potentially leading to death or leaving sequelae in survivors. The epidemiological expression of the disease is influenced by various factors, including the etiological agent, population clusters, socioeconomic characteristics, and climatic conditions. In Brazil, meningitis is a notifiable disease due to its severity, high mortality rate, and irreversible sequelae, especially in children. This study analyzed meningitis cases in Mato Grosso do Sul in 2023, using data from the Notifiable Diseases Information System (SINAN). There were 129 suspected cases recorded, with 80% in Campo Grande. Most patients were discharged from the hospital, especially men aged 20 to 59 years and of mixed race/color. Unspecified meningitis was the most common etiology, followed by bacterial. The chemocytological exam was the most used diagnostic method. Underreporting is a significant challenge, reflecting the need for continuous epidemiological surveillance and preventive measures. It is essential to direct special attention to children and the school environment, where preventive interventions can be particularly effective.

Evaluation of facial expressions for the recognition of parkinsonian fasciations based on artificial intelligence learning

Pedro Henrique Ximenes Ramalho Barros[1], Luma Rodrigues da Silva[1], José Nazareno Alves Rodrigues[1], Rodrigo de Melo Souza Veras[1], Lara Beatriz Alves Batista[1], Samuel de Castro Campos[1], Jonatas Paulino da Cunha Monteiro Ribeiro[1], Dário Correia Negreiros[1], Tiago José Do Nascimento Teixeira Leite[1], Kelson James Almeida[1]

[1]Universidade Federal do Piauí, Teresina PI, Brazil.

Correspondence: Pedro Henrique Ximenes Ramalho Barros; Email: pedrohx587@gmail.com.

Background: Facial recognition technologies are important in genetic, endocrinological, neuromuscular and neurodegenerative diseases. Non-invasive diagnostic tools and strategies based on videos and photos can generate automated facial analysis software whose integration with artificial intelligence learning fosters the development of new products. Facial hypomimia, often present in patients with Parkinson's disease (PD), is characterized by impaired facial expressiveness, with decreased orofacial and eye movements. Thus, based on patterns found in parkinsonian facies, the use of Machine Learning is promising, becoming an auxiliary technological mechanism for identifying facial expressions. **Objective:** To develop a database and an algorithm for recognizing facial image parameters in subjects with idiopathic parkinsonian syndrome, to evaluate its accuracy and to identify the best facial expression for recognizing facial hypomimia. **Methods:** This was an experimental, cross-sectional, non-interventional study that included patients diagnosed with parkinsonian syndrome, assessed by a neurologist using the London Brain Bank criteria, who underwent photo capture of facial expressions (surprise, happiness, fear, disgust, anger and sadness). With the database generated and also using the "FER 2013" database, an algorithm was formulated using technology based on training from examples through supervised learning by inputs and outputs calculated by an unknown function y = f(x) where the pairs (Xn, Yn) of a new function (h), approximate a true function, using a Convolutional Neural Network (CNN). Performance was evaluated using a Binary Classification Confusion Matrix and the information obtained generated total accuracy, precision and recall variables. **Results:** Accuracy for PD patients was 0.18, with recall rates for anger, disgust, fear, happiness, sadness and surprise of 0.00; 0.00; 0.10; 0.57; 0.24 and 0.00, respectively. Patients without PD had an accuracy of 0.17, with recall of anger, disgust, fear, happiness, sadness and surprise of 0.07; 0.00; 0.11; 0.23; 0.24 and 0.00. When a new model using only the emotions of sadness and happiness was analyzed, the accuracy of the method rose to 0.57. **Conclusion:** A database and an algorithm for recognizing facial image parameters in idiopathic parkinsonian syndromes have been developed. The initial accuracy when evaluating 6 emotions was low. The best facial expression for recognizing facial hypomimia was sadness. The artificial intelligence learning method proved to be a potentially promising tool for identifying subjects with parkinsonism.

Evaluation of gait and balance in patients with spinocerebellar ataxia type 1 using wearable inertial sensors

Nadson Bruno Serra Santos[1], Camila Caroso Lobo[1], Rachel Paes Guimarães[1], Fabricio Diniz de Lima[1], Alberto Rolim Muro Martinez[1], Marcondes Cavalcante França Junior[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Nadson Bruno Serra Santos; Email: nadson_bruno@hotmail.com.

Background: Spinocerebellar ataxias (SCA) is a subtype of hereditary cerebellar ataxia, with an autosomal dominant pattern, which presents with cerebellar degeneration, involving multiple pathways that connect to this structure and the brainstem. The natural history of SCA1 involves a long pre-symptomatic period, and the first symptoms starts at the 4th and 5th decade of life, the most common of which are gait ataxia and incoordination, nystagmus and dysarthria. **Objective:** To evaluate gait and balance in patients with spinocerebellar ataxia type 1 (SCA1) using Wearable Inertial Sensors. Materials and **Methods:** It's an open study, cross-sectional, for clinical evaluation of patients with SCA1, comparing to controls. It was recruited 10 patients treated at the Neurogenetics outpatient clinic at the Tertiary Hospital and 10 healthy subjects. The

participants used six inertial sensors Mobility Lab TM (APDM, Inc.) while executing a 3-step protocol (Sitting down and getting up from a chair 5 times; Standing in orthostasis for 30 seconds and Walking in a 10-meter range for 2 minutes). **Results:** The SCA1 and Control groups were composed by 7 women and 3 men, with a mean age of 43.8 years and SARA 9.2 in SCA1 group, and 49.7 years and SARA 0.05 in controls group. The measures that were most related, according to Pearson's correlation were Centroidal Frequency (r=0.689; p=0.010); Step Length (r=0.512; p=0.003) and Axis Area (r=0.206; p=0.022), presenting directly correlation to the severity of the SARA scale. Step Length stands out (d=9.628; p=0.003); Axis area (d=4.520; p=0.022); Turning Time (d=0.366; p=0.002) and Number of Steps (d=0.358; p=0.013) were markers of disease progression with the largest effect size in Cohen's correlation (d). **Conclusion:** This is the pilot study in Brazil with the SCA1 population, revealing that the use of Wearable Inertial Sensors is useful for the evaluation and clinical follow-up of patients with SCA1. Incorporating the data from the Wearable Inertial Sensors into clinical practice can optimize care regarding the balance of our patients, with a great impact on evaluation in clinical trials, given its potential to measure silent progression.

Evaluation of micrornas as biomarkers of malignant evolution in patients with diagnosis of glioma

Caroline Souza dos Anjos[1], Victor Cunha Tirapelli[1], Ana Laura Ribeiro e Silva Stevanato[1], Lucas Cunha Tirapelli[1], José Guilherme Marques Farinha[1], Andressa Romualdo Rodrigues[1], Fernanda Maris Peria[1], Carlos Gilberto Carlotti Jr[1], Mucio Luiz de Assis Cirino[1], Daniela Pretti da Cunha Tirapelli[1]

[1]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: José Guilherme Marques Farinha; Email: zeguifarinha@hotmail.com.

Background: Gliomas are neuroepithelial tumors and correspond to approximately 24.6% of all primary brain tumors. In the last decade, great effort has been made in academic circles to characterize gliomas in an attempt to describe clinical behavior, define prognosis and predict therapeutic response. A current problem in clinical practice is the absence of molecular tools to predict the evolution of gliomas classified as low grade, since during postoperative radiological follow-up these patients may have tumor recurrence with histopathological confirmation of high glioma degree. Tumor transformation in high-grade glioma has a worsening of prognosis and reduction of therapeutic possibilities. **Objective:** To analyze the expression of miR- 124a, miR-138, miR-155, miR-1275 in human primary and peripheral blood samples from patients diagnosed with low and high grade gliomas. **Methods:** MicroRNA expression analyzes were performed using the real-time PCR technique. Sixty-five adult patients (18-65 years of age) with confirmed histopathological diagnosis of glioma with cryopreserved tumor biological material, were analyzed. Information collected in the medical records regarding clinical, epidemiological, clinical and radiological characteristics and time for recurrence and death were collected. Considering a level of significance of 5%, the association of categorical qualitative variables and microRNA expression were performed by the Mann-Whitney test. Survival analysis was performed using the Kaplan-Meier non-parametric method. **Results:** The microRNAs under study did not present hyperexpression in tumor tissue of patients diagnosed with glioblastoma. Only miR-1275 showed increased expression in patients diagnosed with pilocytic astrocytoma and grade II oligodendroglioma. In addition, tumors of low and high grade oligodendroglial lineage demonstrated overexpression of miR-1275. In peripheral blood, significant hypoexpression of miR-1275, miR-124 and miR-138 were observed in a glioblastoma sample. There was also a marked hypoexpression of miR-138 in samples of grade III oligodendroglioma. The microRNAs miR-124a, miR-138, miR- 155 and miR-1275 did not show hyperexpression in tumor tissue of patients diagnosed with GBM. MiR-1275 showed increased expression in patients diagnosed with pilocytic astrocytoma and miR-155 was hyperexpressed only in samples of grade II oligodendroglioma. In addition, tumors of oligodendroglial lineage, of low and high grades, demonstrated hyperexpression of miR-1275 and miR-124a. In peripheral blood, significant hypoexpression of miR-1275, miR-124 and miR-138 were observed in the GBM sample as well as marked hypoexpression of miR-138 in samples of grade III oligodendroglioma.

Evaluation of motor results in patients with Parkinson's disease undergoing deep brain stimulation implantation at the neurological institute of Curitiba

Luiza Gonçalves Fraga[1], Joel Fernando Sanabria Duarte[1], Daniel Benzecry de Almeida[1], Murilo Sousa de Meneses[1], Marcela Ferreira Cordellini[1]

[1]Instituto de Neurologia de Curitiba, Curitiba PR, Brazil.

Correspondence: Luiza Gonçalves Fraga; Email: luizaag.fraga@gmail.com.

Background: Parkinson's disease (PD) is one of the most common neurological diseases and an important cause of disability in individuals of working age. Treatment is aimed at controlling symptoms and there is no therapy capable of curing or stopping the progression of the disease. One of the approved therapies for treatment is DBS. This study evaluated the effectiveness of DBS on motor symptoms in patients who underwent the procedure and who underwent preoperative evaluation with the levodopa overload test. **Objective:** To evaluate the effects of deep brain stimulation (DBS) on motor symptoms in PD in patients undergoing the procedure at the Neurological Institute of Curitiba (INC), a Brazilian tertiary hospital. Compare motor symptoms pre and post-DBS implantation through part III of the MDS-UPDRS, evaluate whether there was a reduction in medication after DBS implantation and assess the impact on quality of life after DBS implantation through the questionnaire on DBS Parkinson's disease (PDQ 39). **Methods:** 8 patients were evaluated before and after DBS implantation. For this purpose, the MDS-UPDRS was used. In addition to motor symptoms, medication reduction and quality of life were assessed using the Parkinson's disease questionnaire (PDQ39). The data were placed in an Excel spreadsheet and then statistically analyzed using the JAMOVI statistical software version 2.5.0. **Results:** The average age at DBS implantation was 62.5 years and average disease duration was 9.89 years. In 87.5% the target was the subthalamic nucleus. There was a reduction in medication after the procedure with a mean difference in levodopa equivalent dose of 337mg (p 0.024). It was shown with statistical significance that DBS improved motor symptoms, either alone (p 0.008) or in conjunction with medication (p 0.032). **Conclusion:** After the implantation of DBS, there was a reduction in symptoms and medication used to treat PD after surgery. The PDQ39 assessment suggests an improvement in quality of life, as seen in another Brazilian study.

Evaluation of MRI findings associated with benign multiple sclerosis

Josué de Almeida David[1], Thomas Vieira de Paula[1], Alfredo Damasceno[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Josué de Almeida David; Email: j219131@dac.unicamp.br.

Objective: This study aims to analyze neuroimaging aspects of benign multiple sclerosis (BMS) and traditional multiple sclerosis patients. **Methods:** Sixty patients from a tertiary MS service were included in the study, with 30 individuals exhibiting an Expanded Disability Status Scale (EDSS) score below 3.0 and a minimum of 10 years since disease onset. They underwent clinical evaluation and analysis of the number of cerebral, infratentorial, and spinal cord T2-hyperintense lesions on Magnetic Resonance Imaging (MRI). More stringent criteria for BMS were also tested. **Results:** Patients with worse clinical prognoses exhibited higher numbers of infratentorial and spinal cord lesions. The traditional MS patients had a mean medullary number of lesions of 4.16, while the BMS patients had a mean of 2,33 lesions (p=0.01). We also found out that 11 patients had no medullary lesions, while there were no traditional MS patients without medullary lesions in the MRI. Additionally, patients with a more stringent criteria for BMS definition did not show different neuroimaging parameters. **Conclusion:** This study shows that spinal cord and infratentorial lesions are associated with a worse clinical prognosis and that low/absence of spinal cord lesions is a hallmark of BMS.

Evaluation of prognosis from admission data in patients diagnosed with stroke accident in a reference hospital in Bahia

Larissa Nunes Almeida dos Santos[1], Joanna Sousa da Fonseca Santana[1], Amanda Hellen Sousa Leal[1], Ana Clara de Lemos Guimarães[1], Mariana Rodrigues dos Santos[1], Gracchо Cardoso da Silva Neto[1], Felipe Oliveira Costa[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Amanda Hellen Sousa Leal; Email: amanda.h.f1@gmail.com.

Background: Stroke encompasses a group of pathologies associated with impaired cerebral blood flow and its vessels, with diverse clinical presentations of high epidemiological relevance worldwide. The management of this urgent clinical condition, from admission, requires complementary tests to monitor conditions that influence therapeutic decisions, such as hyponatremia, hypertension, and hyperglycemia. Therefore, it is essential to understand the impact of these conditions on the patient's prognosis and the association between clinical interventions and mortality. **Objective:** Analyze and describe admission data, prognosis, and mortality outcomes in stroke patients. **Methods:** This is a descriptive, observational, retrospective clinical study based on secondary data, as a preliminary result from a major stroke study with 6,993 patients, collection from the electronic medical records of patients previously admitted to a reference hospital in Salvador, Bahia. The study population comprises patients diagnosed with stroke, aged over 18 years, who were admitted between January 2021 and December 2022. The study sample is non-probabilistic by convenience. The variables of interest are: Age, Sex, Type of Stroke, Capillary Blood Glucose, Diastolic and Systolic Blood Pressure, Serum Sodium on Admission, and Death. **Results:** Data from 221 patients were collected. 122 patients (55%) were female. 128 patients (58%) were aged 65 or older. Ischemic stroke was diagnosed in 82% and hemorrhagic stroke in 13.5%. 59 patients (26.6%) died. Analyzing serum sodium, the highest incidence of deaths, 39.13%, was in patients with values below 135mmol/L. Among patients between 136-145mmol/L, the mortality rate was 25.79%. Regarding capillary blood glucose, patients with values between 126-200mg/dL, 33.3% died; between 200-400mg/dL, the mortality was 37.5%. In patients with blood glucose up to 126mg/dL,

the death rate was 9.62%. Analyzing systolic blood pressure, in patients greater than or equal to 180mmHg, 13.64% died. Those with SBP between 90-130mmHg, 50% died. Regarding diastolic blood pressure, patients greater than or equal to 110mmHg, 29.55% died. Those with DBP between 60-85mmHg, 31.25% died. **Conclusion:** The analysis revealed relevant findings about the clinical outcomes of stroke patients, with a predominance of females and patients aged 65 or older. Ischemic stroke was the most prevalent. The overall mortality rate was 26.6%, with significant variations associated with different levels of serum sodium, capillary blood glucose, and blood pressure. Patients with serum sodium below 135mmol/L had the highest incidence of deaths, 39.13%, those with capillary blood glucose between 200-400mg/dL had a mortality rate of 37.5%. Blood pressure was a crucial factor, with a mortality rate of 50% in patients between 90-130mmHg. These findings highlight the importance of rigorous monitoring and appropriate management of clinical parameters to improve outcomes in stroke patients.

Evaluation of pulse therapy with intravenous methylprednisolone on leprosy neuritis: an observational study on a Brazilian referral center

Eduardo William Farinha Carvalho[1], Ana Clara Nogueira Cezar[1], Ariane Aparecida Correa de Miranda[1], Caio Luiz Nazar Cunha[1], Laura Caroline Felipe de Freitas[1], Lucas Figueira Vieira[1], Lucas Kenzo Ozera[1], Leonardo Peixoto Garcia[1], Isabela Maria Bernardes Goulart[1], Diogo Fernandes dos Santos[1]

[1]Universidade Federal de Uberlândia, Uberlândia MG, Brazil.

Correspondence: Eduardo William Farinha Carvalho; Email: eduardowilliam0603@gmail.com.

Background: During the natural history of leprosy, several patients present immune hyperactivity, known as leprosy neuritis (LN), that can occur before, during, or after multidrug therapy. LN is responsible for the deformities and sequelae present in this disease, making this neuropathy a potentially disabling condition. Therefore, as in other inflammatory neuropathies, intravenous corticosteroids should be considered in the treatment of LN, especially in severe and refractory cases. **Objective:** To evaluate the use of intravenous methylprednisolone in refractory LN in a national reference center of leprosy in Brazil. **Methods:** This observational study included leprosy patients who underwent intravenous methylprednisolone for refractory LN treatment. Epidemiological and clinical data were collected. The following Instruments were used in the evaluation: visual analog pain scale (VAS), Douler Neuropathic 4 questionnaire (DN4), Screening of Activity Limitation and Safety Awareness (SALSA), and the simplified neurological assessment protocol used by the Ministry of Health in Brazil. Data obtained was compared with the results of the initial and end of pulse therapy with methylprednisolone. **Results:** We evaluated 18 patients with a male predominance. The majority (66.7%, 12/18) presented the LR after the end of treatment. After pulse therapy, there was no difference regarding sensory and motor scores in all nerves evaluated, confirming the maintenance of the previously observed deficits. At the beginning of the treatment, 66.7% (12/18) of patients were using oral prednisone at 35.0mg (±12.43). After using methylprednisolone, 38.9% (7/18) of the individuals maintained oral prednisone at a lower dose (16.4mg ±6.3; p=0.002). Regarding the SALSA scale, the score significantly improved at the end of treatment (p=0.020). Regarding neuropathic pain, there was a substantial drop in the DN4 scores from 6.7 (±1.7) to 5.2 (±2.1) (p<0.0001). **Conclusion:** This study showed that pulse therapy with endovenous methylprednisolone in LN was effective in decreasing pain intensity, preventing worsening of sensory-motor function, and reducing the dose of corticosteroids, reflecting the patient's improvement of functionality.

Evaluation of quantitative muscle ultrasound in monitoring the progression of Duchenne muscular dystrophy

Karlla Danielle Ferreira Lima[1], Pedro Henrique Marte Arruda Sampaio[1], Marco Antônio Veloso Albuquerque[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Karlla Danielle Ferreira Lima; Email: karlla.dfl@gmail.com.

Background: Duchenne muscular dystrophy (DMD) is a severe, progressive, muscle-wasting with an X-linked recessive inheritance caused by mutation in DMD gene. It is cause progressive muscle weakness that begins in early childhood in boys. Progressive weakness results in loss of ambulation early, and death from respiratory impairment or cardiac dysfunction. Quantitative muscle ultrasound (QUS) in boys with DMD shows increased echo intensity as muscle is replaced by fat and connective tissue. There are few studies evaluating the patterns of muscle involvement using ultrasound in patients with DMD. **Objective:** To determine the pattern of involvement and its relationship with the evolution of the disease. **Methods:** This is a prospective observational study from a single center, carried out at the Muscle Clinic of a reference center, from January 2022 to July 2023, in 42 patients with DMD between 6-18 years of age (average of 11 years). QUS of 12 muscle groups (axial, appendicular and respiratory), the mobility and thickness of the diaphragm (TE) [thickness during inspiration (Tinsp) and expiration (Texp)] were assessed in all patients using ultrasound and the Image J program. **Results:** In the upper limbs, the most affected muscle was the biceps brachii, while in the lower limbs it was the rectus femoris. Whilst for the respiratory muscles, the intercostal muscle had a higher average involvement than the diaphragm. The correlation between muscle histograms and the age variable was statistically significant only with the 1st interosseous, biceps brachii, medial gastrocnemius and digastric muscles. When evaluating diaphragm mobility using thickness measurement, only one patient had diaphragm paralysis (thickening fraction <20%), at 12 years of age. The average TE was 89%, ranging from 13 to 182%. There was no statistical significance between TE and age, while there was a positive statistical correlation with Tinsp and Texp (p<0.06). **Conclusion:** Our study demonstrated that ultrasound can be used as a method to help monitor disease progression with age, but not all muscles correlate with statistical significance. In the age range studied, there was no reduction in diaphragmatic thickness in patients with increasing age. However, our sample was composed of very young patients with an average of 11 years of age. Interestingly, our results demonstrated a positive correlation between age and Tinsp and Texp, suggesting that in a younger age group, patients may have diaphragmatic pseudohypertrophy. Studies with a larger sample are necessary to better understand diaphragmatic dynamics in DMD patients.

Evaluation of rAAVrh74 antibodies seroprevalence: report from the first tested cohort of Duchenne patients in Brazil

Felipe Franco da Graça[1], Clara Gontijo Camelo[2] , Mariana Rabelo de Brito[1], Marcondes Cavalcante França Jr.[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.
[2]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Felipe Franco da Graça; Email: felipefgraca@hotmail.com.

With the increasing utilization of viral vector-based gene therapies, knowing the seroprevalence of the virus- specific antibodies is crucial for estimating the pool of eligible patients within a population. Recombinant AAV serotype rh74 (rAAVrh74) is a vector used in Delandistrogene Moxeparvovec (DM), the first gene therapy approved for the treatment of Duchenne muscular dystrophy. Its seroprevalence in the north-american population is acknowledged to be low (13.9%). However, these data remain unknown for other demographic groups. In this study, we have assembled, for the first time, a cohort of tested Brazilian patients. Eight patients aged over 4 and under 6 years with a confirmed diagnosis of Duchenne muscular dystrophy were included. Each participant had a single blood sample collected, which was analyzed for total binding antibodies against rAAVrh74 using an enzyme-linked immunosorbent assay (ELISA). Antibody levels below 1:400 were classified as not elevated or seronegative. All eight evaluated patients (100%) exhibited negative titers for the antibody. This data, albeit derived from a limited sample size, corroborates the low prevalence observed in the north-american cohort. Nevertheless, larger studies are required to determine a more representative seroprevalence in the Brazilian population.

https://doi.org/10.5327/CBN240765

Evaluation of sleep perception and presence of daytime sleepiness and its impact on the quality of life of patients with Fabry disease: a case series

Rafaella Resplande Xavier[1], Matheus Gabriel Castro Bezerra[1], Priscila de Paiva Nazareth[1], Sophia Oliva Schommer[1], Vitória Batista e Matricardi[1], Beatriz Fulador[1], Victor Hugo de Souza Silva Gomes[1], Heloise Helena Siqueira[1], Julia Mayumi Yakabe Nelson[1], Manuela Oliveira Alves Victor[1]

[1]Hospital Geral, Cuiabá MT, Brazil.

Correspondence: Beatriz Fulador; Email: beatriz_fulador@hotmail.com.

Background: Fabry disease is a genetic disorder caused by an inborn error of metabolism resulting from a mutation in the X chromosome. This mutation leads to a coding error of the enzyme alpha-galactosidase A, preventing its synthesis and thereby inhibiting the degradation of its specific substrate, globotriaosylceramide (Gb3). Consequently, there is an accumulation of Gb3 in the lysosomes of various organs, leading to a wide variability of symptoms due to its pro-inflammatory and cytotoxic effects, manifesting in nervous, integumentary, renal, and cardiovascular systems. Thus, the disease generates functional limitations both physically, such as pain, general health, and vitality, and socially and emotionally, significantly impacting patients' quality of life and sleep. **Objective:** To evaluate the general aspects of sleep and quality of life impairment in a series of patients with Fabry disease regularly undergoing enzyme replacement therapy. **Methods:** This is an observational, prospective study of a case series of patients with Fabry disease followed by the Neurology Service of HGU in Cuiabá/MT, evaluated between April and May 2024. Structured questionnaires with the following scales were used: Short-Form Health Survey 36 (SF36), Pittsburgh Sleep Quality Index (PSQI), and Epworth Sleepiness Scale (ESS), which were applied to all individuals in this case series. **Results:** Six individuals undergoing Enzyme Replacement Therapy (ERT) were included in this study, with a male-to-female ratio of 1:1 and an average age of 51.6 years (41-69 years). The PSQI evaluated sleep quality, analyzing 7 components with a

final score ranging from 0-21 points. It was concluded that 5 patients had good sleep quality and only 1 evidenced a sleep disorder. Furthermore, daytime sleepiness was assessed using the ESS, which considers the likelihood of the patient dozing or sleeping in different situations. According to the results obtained, no patient showed excessive sleepiness, with 4 exhibiting normal sleepiness and 2 showing moderate sleepiness. Regarding quality of life assessed by the SF-36 questionnaire, 8 domains were observed, each varying from 0-100%. The outcome identified that almost all categories are compromised, with the worst outcomes in domains involving emotional aspects (83.3%), social aspects (75%), functional capacity (74%), and limitations due to physical aspects (66%). **Conclusion:** After analyzing the results, it is concluded that the evaluations of the validated scales are essential in the follow-up of these patients and should be performed periodically, aiming to identify disabilities and limitations and thus propose the best pharmacological and non-pharmacological treatment for these patients, along with a multidisciplinary team, aiming for a better quality of life

Correspondence: Ana Luiza Sandoval Goes; Email: analuizagoes@gmail.com.

Background: Autosomal dominant cerebral arteriopathy with subcortical infarctions and leukoencephalopathy (CADASIL) resulting from mutations in the NOTCH 3 gene on chromosome 19 is considered a rare condition and is the most prevalent hereditary small vessel vascular disease. Course with ischemic stroke, migraine and vascular dementia. It has a broad neuropsychiatric spectrum including mood changes, apathy and depression. The progression of the disease leads to the emergence of neurological sequelae and loss of functional capacity, physical and mental disability. **Objective:** This work aims to evaluate functional capacity, the occurrence of disability and cognitive decline in 28 patients from 11 families with CADASIL. **Methods:** Standardized functionality scales were applied, such as the modified Rankim scale (IRM), Barthel index (BI) and cognitive screening with the Montreal Cognitive Assessment (MoCA). The SPSS tool was used for statistical analysis of the results. **Results:** 28 cases from 11 families with lesions detected in the NOTCH3 gene were evaluated. 16 (57.1%) were women, 12 (42.9%) men; the average age was 46.36 years, the youngest age 22, the oldest age 67, the sample standard deviation was 12.53 years, coefficient of variation of 27.02%. The MoCA partnered 13 (46.4%) with cognitive impairment and 15 (53.6%) preserved cognitive impairment; MRI without symptoms in 19 (67.9%), without disability in 3 (10.7%), moderate disability in 5 (17.9%) and severe disability in 1 (3.6%); BI with a degree of severe functional dependence in 1 (3.6%), a degree of mild dependence in 8 (28.6%) and functional independence in 19 (67.9%). **Conclusion:** The application of the functionality and cognitive screening scales evaluated the sequelae of the disease, which were expressed in varying degrees of functional disability, physical disability and cognitive impairment. The sample had a predominance of women, the age variability between the second and sixth decade of life was compatible with literature data, with age being a homogeneous set. The IRM detected that the majority were able to carry out all their activities and take care of their own interests, showing no symptoms or moderate disability. The IB showed that the majority were functionally independent, although cases of severe disability for ADLs were identified. The high prevalence of cognitive impairment shows that neuropsychiatric symptoms can be present even in asymptomatic patients without functional disability. This study seeks to collect unprecedented epidemiological data on functionality in Brazil and be useful for adapting and collaborating in the development of health strategies.

Evaluation of the hospitalization landscape for multiple sclerosis in children and adolescents aged 1 to 19 across Brazilian regions over the past 5 years

Marina Ottmann Boff[1], Ingrid Lizier Couto Pereira[1], Luísa Castro Gomes[1], Taís Michele Werle[1], Eduarda Gandolfi Horst[1], Gabriella Sityá Moojen da Silveira[1], Paola Saraiva Marinho[1], Marina Maestri Denardin[1], Frederico Orlando Friedrich[1], Magda Lahorgue Nunes[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Marina Ottmann Boff; Email: mottmannboff@gmail.com.

Background: Multiple sclerosis (MS) is an autoimmune condition affecting the myelin sheath of neurons, leading to degenerative inflammation. It's more common in women but can occur in both sexes. Typically diagnosed between ages 20 and 40, sometimes even in childhood. Its cause involves genetic predisposition and environmental factors. While there's no cure, current treatments aim to manage symptoms and slow disease progression, enhancing patients' quality of life. **Objective:** To evaluate the landscape of MS hospitalizations in children and adolescents under 1 to 19 years old in Brazil over the past 5 years. **Methods:** This is an ecological, cross-sectional, descriptive, and quantitative study using data from the Hospital Information System available on DATASUS. The period analyzed was from January 2019 to December 2023, considering the place of residence. The variables investigated included hospitalizations, average length of stay, deaths, mortality rate, and sex by region. The data were tabulated in Microsoft Excel and analyzed using descriptive statistics. **Results:** The total number of hospitalizations in children and adolescents was 1,589, with an average length of stay of 4.5 days, and there was only 1 death in all of Brazil (mortality rate of 0.06), which occurred in the 15 to 19 age group in the North region. There was 1 hospitalization in children under 1 year old, with an average stay of 8 days and no deaths; 4 hospitalizations among children aged 1 to 4 years, with an average stay of 10.8 days and no deaths; 45 hospitalizations among children aged 5 to 9 years, with an average stay of 8.6 days and no deaths; 289 hospitalizations among children aged 10 to 14 years, with an average stay of 6.9 days and no deaths; 1,250 hospitalizations among adolescents aged 15 to 19 years, with an average stay of 3.7 days and 1 death. Hospitalizations were more prevalent in females (62.2% of the total hospitalizations) across all regions and most age groups, except in the Central-West region for the 5 to 9 years (66.67%) and 10 to 14 years (70.0%) age groups, where hospitalizations were more frequent in males. The average length of stay varied among regions: 8.1 days in the North, 10.6 days in the Northeast, 4.5 days in the Central-West, 3 days in the Southeast, and 5.8 days in the South. **Conclusion:** the data reveal an increase in hospitalizations with age, peaking between 15 and 19 years. The average duration of hospitalizations decreases with age. Hospitalizations were more common among females in all regions, suggesting gender disparities in exposure or response to the disease. The average lengths of hospital stay varied among regions, possibly due to differences in healthcare systems and socioeconomic factors. The observed mortality rate in this study was low, n=1, corresponding to 0.06% of the total hospitalizations. These findings can guide prevention strategies and resource allocation for hospitalizations in children and adolescents.

Evaluation of the prevalence of functional neurological symptom disorder in an outpatient epilepsy clinic of a tertiary hospital in Cuiabá and the importance of its recognition

Luis Felipe da Cruz Macedo[1], Tiago Ferreira Portela[2], Thyago dos Santos Amorim[2], Bruno Reginato Gumiero[1], Bianca Barbosa Araldi[1], Luisa Franciscatto[1], Luiz Henrique Granja de S. Vieira Miller[1], Marlon Figueiredo Alves Correa[1], Nathalia Carvalho Braga[1], Larissa Kozow Westin[1]

[1]Empresa Cuiabana de Saúde Pública, Cuiabá MT, Brazil.
[2]Universidade Federal do Mato Grosso, Cuiabá MT, Brazil.

Correspondence: Luis Felipe da Cruz Macedo; Email: luisfcmacedo@gmail.com.

Background: Functional neurological symptom disorders or psychogenic non-epileptic seizures (PNES) are paroxysmal events that resemble clinical episodes of epileptic seizures, due to motor, sensory or cognitive events that are not associated with electrical brain discharges or epileptiform activity in electroencephalographic recordings. There are no specific seizure presentation in PNES, requiring an experienced epilepsy specialist to suspect functional seizures. The definitive diagnosis is made using a video electroencephalogram (VEEG) and treatment is transdisciplinary, with psychological and psychiatric follow-up in collaboration with neurology. **Methods:** We carried out a cross-sectional study at an epilepsy treatment center (ETC) created in February 2024 at a tertiary hospital in Mato Grosso, Hospital Municipal de Cuiabá - HMC. We reviewed medical records from the beginning of the ETC's activity until June 24, 2024. The frequency of diagnoses, age, gender, use of antiepileptic drugs, multidisciplinary referral and VEEG (7-day protocol) were evaluated descriptively and the graphs were made using the R Studio program. **Results:** The HMC epilepsy treatment center (ETC) started on February 21, 2024 with 109 patients diagnosed with epilepsy and 14 with suspected PNES (12%), 7 men and 7 women (1:1). Under investigation from PNES included 6 patients (42%) with confirmed diagnoses with VEEG, 8 patients (57%) with suspicion still had no VEEG, and 3 patients (21%) were being evaluated previously for refractory epilepsy. Concerning antiepileptic drugs, 6 patients remained on the medication for the time being (42%) and 8 (57%) were completely withdrawn, and these same patients are undergoing multidisciplinary follow-up with psychiatry. Overall, 12 VEEGs have been completed at the CTE to date, with the PNES therefore representing 50% of the VEEGs completed in the 3 months since the ETC was set up. **Conclusion:** PNES are a major challenge for diagnosis and appropriate treatment, since their definitive diagnosis requires VEEG, a long-term exam that is difficult to access outside of large centers in order to conclude the diagnosis, withdrawal of antiepileptic medication and multidisciplinary follow-up, improving the quality of life of these patients. Likewise, PNES are great imitators of refractory epilepsies, and it is imperative to epilepsy treatment centers provides access to VEEG to confirm PNES as a important imitators of inadequate seizure control.

Correspondence: Camila Pezente Dal Toé; Email: camilapezente@hotmail.com.

Background: After conventional physiotherapy-based treatment, some sequelae of Stroke (AVE) persist. Transcranial Magnetic Stimulation (TMS), which modulates neuroplasticity, shows promise in restoring balance and motor function in upper and lower limbs. **Objective:** To evaluate the effectiveness of the TMS protocol in rehabilitating post-stroke patients in Criciúma, Santa Catarina. **Methods:** Eight electronic records were analyzed using Tinetti, Dash, and Berg functional scales to assess balance and motor function recovery. Scales were administered at the beginning and end of the TMS protocol, with scores analyzed statistically. **Results:** Results demonstrated significant improvements in balance rehabilitation as measured by the Tinetti scale (mean 7.80±5.97 before and 18.60±7.30 after the protocol, p=0.002) and Berg scale (from 43.00 to 54.00). Gait, also assessed by the Tinetti scale, showed increased scores (7.80±5.97 to 18.60±7.30, p=0.002). Regarding upper limbs, the DASH scale revealed a reduction in motor deficit (89.33±22.50 to 68.33±30.02, p=0.181) following TMS. **Conclusion:** These findings suggest that Transcranial Magnetic Stimulation may be an effective approach in rehabilitating post-stroke patients, particularly in improving balance and motor function.

Evaluation of the select score as a predictor of risk for epilepsy development in patients with ischemic stroke

Darah Fontes da Silva Assunção[1], Marcelle Sanjuan Ganem Prado[2], Gabriel Chung[2], Filipe Brito Ferraz da Silveira[2], Marina Buldrini Filogonio Seraidarian[1], Vanessa Cristina Colares Lessa[2], Fábio Barreto Cabral[2], Cristine Mella Cukiert[2]

[1]Universidade de São Paulo, São Paulo SP, Brazil. [2]Santa Casa de Misericórdia de São Pauilo, São Paulo SP, Brazil.

Correspondence: Marcelle Sanjuan Ganem Prado; Email: cellesanjuan@yahoo.com.br.

Background: In patients with ischemic stroke, the risk of recurrence after a first late-onset seizure is estimated at seventy per cent when diagnosis can be established. Several factors may predict the risk of epilepsy development, including stroke severity, etiology, affected arterial territory, presence of cortical involvement, and occurrence of acute symptomatic seizures, variables assessed by the SeLECT score. **Objective:** To analyze whether the variables selected in the SeLECT score were predictive of risk in the studied population. **Methods:** Retrospective observational study, reviewing medical records of patients followed in a cerebrovascular disease outpatient clinic over a 2-year period, aged 18 years and older, diagnosed with epilepsy and ischemic stroke. **Results:** Thirty-seven patients were evaluated, with a mean age of 50.32 years. The NIHSS frequency was 62.2% for moderate (4-10). Regarding etiology classified by TOAST criteria, 16.2% were attributed to large artery atherosclerosis and 18.9% to cardioembolism. Cortical involvement was observed in 81.1% of patients. Most cases, 83.8%, involved the ACM territory. The occurrence of acute symptomatic seizures, a variable with higher scores in the SeLECT score, was observed in 13.5% of the population. Among the patients, 16.2% underwent acute reperfusion therapy. No statistical significance was found when comparing the total SeLECT score and TOAST classification. However, significant association (p<0.05) was demonstrated when analyzing higher SeLECT scores with increased risk of epilepsy development, higher NIHSS scores, presence of cortical involvement, ACM territory affected, and occurrence of acute symptomatic seizures. Age at stroke onset, patient sex, reperfusion therapy, occurrence of hemorrhagic transformation, and assessed comorbidities showed no significant association with SeLECT scores and likely did not increase seizure occurrence risk. **Conclusion:** The SeLECT score showed applicability in predicting late seizures after stroke. No other predictors among the analyzed variables were observed. The importance of acute reperfusion therapy as a seizure-inducing factor remains uncertain in this scenario. Clearer insights may be gained from prospective multicenter studies, guiding follow-up of high-risk patients.

Correspondence: Iara Senem; Email: iara.senem@usp.br.

Background: Hereditary Transthyretin Amyloidosis (ATTRv) is a systemic disease that primarily affects the peripheral and autonomic nervous systems. Recently, the Central Nervous System has been investigated. Besides cognitive dysfunction, amyloid deposition was identified in the brain, cerebellum, leptomeningeal and subarachnoid meningeal vessels, and the brainstem. In vivo brain MRI studies showed diverse results, such as leptomeningeal involvement, microbleedings, cortical atrophy, and, in some cases, no abnormalities were observed. To date, studies have not investigated cortical and subcortical areas using software for automatic brain segmentation. **Objective:** We aimed to investigate the brain volume, and cortical thickness in patients with ATTRv amyloidosis. **Methods:** 3DT1-weighted images (T1) of brain MRI of twenty ATTRv patients (mean age=41.7±9.2) and 23 sex/age-matched healthy individuals (41.7±9.3) were analyzed. Cortical measures of volume and thickness were obtained for both groups through FreeSurfer software ("crecon-all" script). SPSS software was used for the statistical analyses. **Results:** Compared to controls, ATTRv patients displayed smaller volumes of cerebellum. No difference between the groups was found in the hypothalamus volume. The study indicated a thinner cortical thickness in ATTRv amyloidosis in the following regions: banks of the superior temporal sulcus, fusiform gyrus, inferior, superior, and middle temporal gyri, orbitofrontal cortex, pars opercularis, pars orbitalis, lateral orbitofrontal cortex, precentral gyrus, inferior parietal cortex, supramarginal and postcentral gyri, occipital lateral cortex, pericalcarine cortex, cuneus, and insula. Disease duration was negatively correlated with cortical thickness of insula, pars opercularis and inferior and superior temporal gyri. No correlation was found between disease duration and the cerebellum volume. **Conclusion:** The study showed a thinner cortical thickness in specific brain regions in ATTRv amyloidosis. The reasons for this finding and its relationship with amyloid deposition are not fully understood. Further research involving a larger number of patients is necessary to confirm these findings and identify their clinical manifestations.

Evolutionary profile of the Walking test and Rotterdam scale in a group of patients with late-onset Pompe disease undergoing enzyme replacement therapy

Beatriz Fulador[1], Rafaella Resplande Xavier[1], Albérico Rocha Lima Neto[1], Rhaymysom Jasmy Gomes Abreu[1], Helen Luiza Silvestrini[1], Carine Calegaro[1], Letícia Lage Silva[1], Hingrid Cristine Arruda de Oliveira[1], Victor Hugo de Souza Silva Gomes[1], Heloise Helena Siqueira[1]

[1]Hospital Geral, Cuiabá MT, Brazil.

Correspondence: Beatriz Fulador; Email: beatriz_fulador@hotmail.com.

Background: Pompe disease (PD), also known as Glycogen Storage Disease II, is a genetic disorder caused by pathogenic variants in the gene encoding acid alpha-glucosidase (GAA), resulting in GAA deficiency and consequent glycogen accumulation in the lysosomes of tissues. Due to muscle involvement, patients experience proximal muscle weakness, often progressive, which is directly related to their motor functionality. Motor impairment symptoms are usually the first manifestation of the disease. Several tests and scales are proposed for its evaluation, notably the Rotterdam Handicap Scale (RHS) and the 25-Foot Walk Test (T25-FW). According to major studies, the motor functionality of patients diagnosed with PD has a median 25% lower than that of healthy adults based on the Rotterdam scale analysis. In addiction, the motor system responds significantly better than the respiratory system to enzyme replacement therapy (ERT). **Objective:** To comparatively evaluate the results of motor functionality assessment tests in a group of patients with PD who are regularly using enzyme replacement therapy. **Methods:** This is a comparative study conducted through the application of validated scales and tests to assess the motor function of patients with Pompe Disease: the Rotterdam Handicap Scale (RHS) and the 25-Foot Walk Test (T25-FW), in the years 2017 and 2024, in a group of five patients regularly using enzyme replacement therapy (alpha-glucosidase) at a rare diseases center. **Results:** Five individuals were included in the study, of which 3 were men and 2 were women, with ages ranging between 35 and 66. All have the late-onset form of the disease. In terms of motor functionality assessment, the average RHS score increased from 27.2 in 2017 to 27.6 in 2024, with 9 being the minimum score and 36 the maximum score for the ability to perform activities. Similarly, the average time for the T25-FW decreased from 15 seconds (ranging from 8 to 20) in 2017 to 11 seconds (ranging from 5 to 18) in 2024. Of the 5 patients, only one showed an increased time to complete the test over the 7 years, from 8 to 18 seconds, representing a 125% increase. However, it is noteworthy that this patient suffered a stroke between assessments, resulting in significant gait impairment. The other patients had no additional comorbidities. **Conclusion:** Enzyme replacement therapy (alpha-glucosidase) proved effective and had a positive impact on the motor functionality of the patients in this study, although one patient showed less improvement due to the presence of another pathology. Therefore, it is concluded that the routine and periodic use of validated assessment scales is essential for monitoring the limitations and disabilities of these patients, in order to evaluate the need for therapeutic changes, the association of adjunct therapies such as motor physiotherapy, and for screening for potential comorbidities that may cause unexpected and sudden clinical deterioration.

Evolutive course of recovery of transcortical motor aphasia following focal resections in the frontal lobe for refractory epilepsy

Eliseu Paglioli[1], Rafael Paglioli[1], William Martins[1], Fernanda Schuh Martins[1], Vicenzo Zarpellon[1], Thomas Frigeri[1], Victoria Schvartzman[1], Natalie Donida[1], Bibiana Thome[1], André Palmini[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Andre Luis Fernandes Palmini; Email: alpalmini@gmail.com.

Background: Rationale and objective: Since the description by Norman Geschwind of the disconnection syndromes, neurologists began to understand deficits in the so-called higher cortical functions as also resulting from subcortical lesions in white matter tracts connecting specific cortical regions. Perhaps few neurological syndromes illustrate this concept so well as the aphasias. From a simplistic view of "Broca's versus Wernicke's" neurology has evolved to the description of several other types of aphasia, resulting from the disconnection between these and other cortical regions. When aphasias result from stroke, lesions in the affected territories often involve a number of cortical and subcortical structures that compound a complex clinical picture, with variable perspectives of functional recovery. On the other hand, in well delineated, limited resections performed to resect epileptic foci it is possible to analyze both symptomatology and evolution in "pure" syndromes. **Objective:** Here, we present the clinical picture and the evolution toward complete recovery over days and weeks of two patients with focal cortical dysplasia (FCD) in the middle frontal gyrus of the dominant (left) frontal lobe (dMFG) who had post-operative transcortical motor aphasia. **Methods:** Two women (#1: 17yo; #2: 40 yo) with refractory seizures due to FCD in the dMFG underwent resections of the epileptogenic zone following presurgical evaluation. They had normal neurological examination preoperatively and objective motor and language evaluations were performed daily in the first week after surgery, documented in video. Following discharge, evaluations were weekly, through simple tests applied and documented by relatives. Post-op MRIs were obtained in both. **Results:** Both became seizure free, except for brief seizures in patient #1 in the immediate post-op period. In the first few days, neither patient could start spontaneous speech, although comprehension and repetition were intact. Answers to simple questions were only possible, albeit incompletely, following induction by the examiner, ie, options were given by the examiner and selected by the patient. Similar difficulties with writing (only after priming) were also observed in patient #1. Post-op MRIs showed resection of the dMFG and discrete edema of the underlying fibers. Following 1 week, both could hesitantly already begin sentences and produce spontaneous answers. Complete recovery was seen between 30 and 60 days after operation and both are now fully functional. **Conclusion:** Transcortical motor aphasia is a disconnection syndrome due to involvement of fibers connecting the supplementary motor and Broca's areas. Resections of the dMFG can lead to transcortical motor aphasia, yet with excellent functional recovery, providing resection carefully respects the underlying white matter.

Excessive daytime sleepiness in Parkinson's disease: an observational analysis

Luma Santos Arruda[1], Diego Monteiro de Carvalho[2], Marcello Facundo do Valle Filho[2], Marcus Vinicius Della Coletta[3], Alvaro Siqueira da Silva[3], Raissa Costa Said[4], Débora de Oliveira Ferreira[1], João Victor da Costa Nunes[4], Anelisa Campana Itinose[4], Carlos Mauricio Oliveira de Almeida[3]

[1]Centro Universitário Fametro, Manaus AM, Brazil.
[2]Universidade Federal do Amazonas, Manaus AM, Brazil.
[3]Fundação Hospital Adriano Jorge, Manaus AM, Brazil.
[4]Universidade do Estado do Amazonas, Manaus AM, Brazil.

Correspondence: Luma Santos Arruda; Email: lumaarruda10@hotmail.com.

Background: Parkinson's disease (PD) is the second most common neurodegenerative disease in the elderly, second only to Alzheimer's disease, representing about 1% of the population over 60 years old. In PD sleep disorders are observed in up to 90% of patients. Literature data demonstrate that Excessive Daytime Sleepiness (EDS) occurs in 50 to 80% of PD patients and has multifactorial causes, such as medications, sleep disorders, psychiatric disorders, and the neurodegenerative process itself. **Objective:** To analyse the association between the Epworth Sleepiness Scale (ESS) in patients with PD at early/intermediate stages according to the Hoehn-Yahr (H&Y) scale. **Methods:** This is a cross-sectional observational study, with a sample composed of PD patients from the neurology clinic at the reference hospital in Manaus-AM. The study was approved by the local Ethics Committee under Certificate of Presentation of Ethical Consideration No. 58684622.2.0000.0007. Inclusion criteria were: PD (aged over 18) diagnosed according to the London Brain Bank criteria, with staging 0-3 on the H&Y scale without a diagnosis of obstructive sleep apnea (OSA). Patients were excluded if they had a diagnosis of dementia, OSA (AHI >15/h by polysomnography), atypical parkinsonism, neoplastic disease, systemic diseases, alcohol abuse or use of illicit drugs, or language or speech articulation disorders that prevented the application of the questionnaires. After acceptance into the study, patients were subjected to the application of clinical questionnaires, ESS and the disease staging (H&Y). EDS was defined by a score greater than 10 points on the ESS. **Results:** Thirty-three patients were evaluated, with 75% presenting with EDS. No significant association was observed between those who presented with or without EDS and the stage of the disease (H&Y) (p=0.94), nor with anxiety ($\chi2$=4.8; p=0.11) or depression ($\chi2$=3.29; p=0.19). **Conclusion:** Our study confirms the literature data that PD patients frequently present with EDS (50-70%). We did not observe an association between this sleep disorder and mood disorders or the stage of the disease. As we know, the cause of EDS is multifactorial and sometimes involves the neurodegenerative process affecting the regulatory centers of wakefulness and sleep.

Excruciating pain during exercise reveals colloid cyst: a case of potential life-threatening risk

Vanessa Gil Humberto dos Santos[1], Amanda Melo Leite Leão[1], Laís Borneo Moreira[1], Thais Pereira Albernaz de Souza[1], Jorge Luiz Alves[1], Pollyana Marcela Silva de Farias[1], Lais Felix Teixeira da Cunha[1], Laís Borneo Silva de Farias[1]

[1]Universidade Unigranrio Afya, Duque de Caxias RJ, Brazil.

Correspondence: Vanessa Gil Humberto dos Santos; Email: vanessaterapia@hotmail.com.

Case presentation: A 42-year-old Italian man, a regular practitioner of physical activities, experienced sudden and intense head pain during a weightlifting session while performing a high-load isometric exercise on the leg press machine. The pain, described as excruciating headache, occurred without associated autonomic signs such as nausea, vomiting, or visual changes. Due to the persistence of the pain, he sought medical attention a week after the episode. Cranial magnetic resonance imaging (MRI) revealed the presence of a colloid cyst in the third ventricle. A more conservative approach was chosen, with regular monitoring and analgesic measures for pain relief. **Discussion:** Effort-induced headache is a classic symptom in patients with colloid cysts, occurring due to increased intracranial pressure during activities that elevate intrathoracic pressure and, consequently, intracranial pressure. High-intensity isometric exercises, such as the leg press, can exacerbate this condition, leading to episodes of intense pain. Additionally, the headache can be positional, worsening when the patient is lying down or inclined.The diagnosis of a colloid cyst is typically confirmed through MRI. In this patient's case, the MRI revealed a colloid cyst in the third ventricle, corroborating the etiology of the headache.Colloid cysts pose a risk of growth, especially in young men, and can obstruct the foramen of Monro, resulting in hydrocephalus and increased intracranial pressure, which can lead to sudden death, if not properly treated, causing na emergency situation that requires immediate intervention. The management of colloid cysts can range from conservative to surgical, depending on symptoms and the risk of complications. In the presented case, a conservative approach was chosen. **Final comments:** This case illustrates the importance of considering colloid cysts as a potential cause of sudden and intense headache in patients undergoing intense physical exercise. Although rare, colloid cysts can present significant clinical symptoms that impact the patient's quality of life. Early diagnosis and appropriate management are crucial to avoid serious complications, including hydrocephalus and the risk of sudden death. Conservative management can be a viable option for asymptomatic or mildly symptomatic patients, while surgical intervention is reserved for cases with severe symptoms or risk of complications. This case report contributes to the clinical understanding of colloid cysts and highlights the need for a comprehensive diagnostic approach in patients with sudden headache following physical exercises. Awareness of this condition can lead to quicker diagnoses and more effective treatments, improving clinical outcomes for patients.

Experience in the switch from alglucosidase to avalglucosidase in real-life late-onset Pompe disease treatment

André Macedo Serafim Silva[1], Michele Abdo Paiva[1], Clara Gontijo Camelo[1], Ana Lucila Moreira[1], Edmar Zanoteli [1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Andre Macedo Serafim da Silva; Email: macedosera@gmail.com.

Background: Late-Onset Pompe disease (LOPD) is an inherited condition caused by glucogen accumulation due to deficiency of acid alfa- glucosidase and consequent muscle weakness and respiratory insufficiency. Enzyme replacement therapy (ERT) with alglucosidase alfa has been considered useful to treat LOPD in clinical trials, case series and real-life studies. Recently, a new ERT with avalglucosidase has been demonstrated as non-inferior to alglucosidase, with the promise of better outcomes in the clearance of glycogen in the muscle. **Objective:** To describe the real-life experience in the switch from alglucosidase to avalglucosidase in LOPD patients treated with ERT. **Methods**: We retrospectively reviewed all medical records from LOPD patients followed in a tertiary neuromuscular center from Jan 2019 to May 2024. Patients who changed the ERT therapy were analyzed according to timed tests, forced vital capacity (FVC) before and after the ERT switch. **Results:** Fourteen LOPD patients with regular treatment with ERT were identified from the neuromuscular clinic records. Two of them switched from

alglucosidase to avalglucosidase. One male patient, diagnosed at 41 years of age presented progressive worsening of respiratory symptoms and FVC, needing continuous non-invasive ventilation, despite alglucosidase treatment for four consecutive years. After two years of changing the treatment to avalglucosidase his FVC increased from 64% to 75% and 10m walk test improved from 25 seconds to 15 seconds. The other male patient, diagnosed at 46 years of age were using doble dosis of alglucosidase (20mg/kg weakly) over a period of two years, with stable respiratory and motor condition. After six months of switch to avalglucosidase, his FVC improved from 52% to 55% and his 6-minute walk-test increased from 390m to 460m. **Conclusion:** Two out 14 LOPD patients in our center switched ERT from alglucosidase to avalglucosidase, and this Brazilian single-center experience shows a trend of better motor e respiratory outcomes with the new generation ERT, like other real-life reported studies. Further studies are still needed to demonstrated the superiority of avalglucosidase over alglucosidade in treating Pompe disease.

Experience with the use of cladribine in patients with multiple sclerosis at the neuroimmunology outpatient clinic of Faculdade de Medicina ABC

Victor Ezaki Alves Silva[1], Ana Claudia Piccolo[1], Eduardo Macedo de Souza Tieppo[1], Renato Morais Bueno[1], Rayanne Pereira Mendes[1], Guilherme Bitencourt Barbosa[1]

[1]Faculdade de Medicina do ABC, Santo André SP, Brazil.

Correspondence: Victor Ezaki Alves Silva; Email: ezaki_victor@hotmail.com.

Background: Multiple sclerosis (MS) is a chronic autoimmune disease affecting the central nervous system (CNS), characterized by inflammation and neurodegeneration. Diagnosis relies on clinical examination, laboratory tests and radiological findings. Long-term treatment involves disease-modifying therapies (DMTs), among which Cladribine is an option. It is an oral administered medication with moderate to high efficacy, exerting cytotoxic action on B and T lymphocytes by inhibiting DNA synthesis. Food and Drug Administration (FDA) in United States approved Cladribine in 2019. In 2023 it was incorporated by Brazil SUS, directed for patients who are unresponsive to other DMTs. **Objective:** To report the experience made at a Neuroimmunology reference center in Santo André - SP, Brazil, with the usage of Cladribine regarding the clinical and radiological efficacy in MS patients. **Methods:** It is a retrospective observational study, including patients with regular follow up at our NeuroImmunology outpatient clinic of ABC Medical School, from August 2020 to December 2023. Patients that were using Cladribine during this period were included, while patients not treated with Cladribine were excluded. Seven participants were included, and each one received Cladribine at a dose of 1.75mg/kg per year for two years. Epidemiological data, clinical history, neurological examination (including Expanded Disability Status Scale - EDSS), and contrast-enhanced magnetic resonance imaging (MRI) of the brain and cervical and thoracic spine were analyzed. Assessments were made before treatment initiation until two years post-second dose of Cladribine. Therapeutic failure was considered a relapse of the disease and/or radiological activity, such as lesions with contrast enhancement or an increase in the number or volume of lesions on MRI. Brain atrophy on MRI was not evaluated. **Results:** Results showed therapeutic failure in 3 patients (42.8%) and effectiveness in 4 patients (57.2%). All patients had highly active disease, however the 3 patients with therapeutic failure using Cladribine had previous unsuccessful experiences with multiple DMTs and aggressive MS disease. Treatment of MS offers diverse therapeutic strategies for disease phenotypes and stages. Cladribine, has already been proven as an effective option for the treatment of MS and is an avaluable DMT for this therapeutic spectrum. Its inclusion in SUS provides an option for the management of patients with MS, like those who have not previously used DMTs, as those have experienced relapses despite prior DMT use. Cladribine may present therapeutic failure in patients who already present an aggressive, highly active disease, with a high number of lesions on MRI and functional incapacity

Experience with use of rituximab in a patient with Susac syndrome: a case report

Allefy Beltrão Albano[1], Ana Rosa Santana[2], Eduardo Sousa de Melo[1], Paulo Felipe Bezerra Silva dos Santos[3], Evelliny Gomes da Silva[1], Fabrício Martins Veras[1], João Pedro Matos de Santana[1], Letícia Klabinske Marques Monteiro[1], Amanda Sampaio de Sá[3]

[1]Universidade Federal de Pernambuco, Hospital das Clínicas, Recife PE, Brazil.
[2]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.
[3]Universidade Federal de Pernambuco, Recife PE, Brazil.

Correspondence: Allefy Beltrão Albano; Email: allefymed@gmail.com.

Case presentation: A 34-year-old male patient presented to our service in 2021 for investigation of a condition characterized by progressive crural spastic paraparesis with evolution since 2019, low visual acuity of recent onset, and subacute cognitive-behavioral condition. She had been diagnosed with Multiple Sclerosis in another service, but no follow-up. On physical examination, he presented spastic paraparesis and global hyperreflexia. Sensitivity preserved. On examination of cranial nerves, fundoscopy did not show visible alterations, Rinne's test denoting decreased auditory and bone conductions, with the former prevailing. Magnetic resonance imaging of the brain and spinal cord showed central injuries in the corpus callosum ("snowballs"), with preservation of the most peripheral fibers, which were better evidenced in T2/FLAIR sagittal sequences. Lumbar puncture showed an increase protein (86mg/dL) and white cells(9 with 88% of neutrophils). He also performed ophthalmological investigation with Optical Coherence Tomography, which showed previous retinal ischemic alterations without major clinical repercussions, and audiometry showing bilateral sensorineural loss for high frequencies (6000-8000 Hz). In view of the main diagnostic hypothesis being Susac syndrome, the patient received pulse therapy with methylprednisolone for five days followed by immunosuppressive therapy with oral azathioprine, showing no clinical response over the following months, being hospitalized again in 2023 due to the progression of weakness and the appearance of urinary and fecal incontinence. In this context, the patient received a new pulse therapy and started modifying therapy with Rituximab, with semiannual doses of 1g. Since then, he has been showing progressive recovery of functionality, with a decrease in spasticity and pattern of weakness in the lower limbs, in addition to progressive sphincter control, denoting improvement in quality of life. **Discussion:** Susac syndrome is a rare, fluctuating and progressive disease caused by autoimmune-mediated occlusion of microvessels in the brain, retina and inner ear which are responsible for the clinical triad characterized by encephalopathy, visual disturbances caused by retinal artery ischemia and sensorineural hearing loss. Its treatment consists of initial administration of pulse therapy with methylprednisonolonone and maintenance therapy with disease modifying immunosuppressive drugs, as Rituximab, an anti-CD20 monoclonal antibody, being a first- line option for this pahtology which is still rarely mentioned in the literature. **Final comments:** The patient in this case presents clinical and radiological criteria for the diagnosis of Susac syndrome. The use of Rituximab associated with progressive clinical improvement, without progression of deficits and apparent improvement of existing ones evidenced in the last outpatient visits, make this drug a good option for the disease-modifying treatment of the syndrome.

Exploratory study of cognitive dysfunction and brain mri correlates in hereditary transthyretin amyloidosis

Iara Senem[1], Maria Paula Foss[1], Carolina Lavigne-Moreira[1], Antonio Carlos dos Santos[1], Pedro J. Tomaselli[1], Jan Axelsson[2], Jonas Wixner[2], Renan Flávio de França Nunes[3], Marcondes Cavalcante França Júnior[3], Wilson Marques Jr.[1]

[1]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto SP, Brazil.
[2]Umeå University, Umea, Sweden.
[3]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Iara Senem; Email: iara.senem@usp.br.

Background: Hereditary Transthyretin Amyloidosis (ATTRv) is a systemic disease that mainly impacts the heart and the peripheral nervous systems. The most common mutations (ATTRV30M (p.V50M) and ATTRV122I (p.V142I)) result in two main phenotypes: polyneuropathy and cardiomyopathy, respectively. Recently, it was recognized the involvement of the central nervous system in ATTRV30M amyloidosis. The amyloid deposition was identified in the leptomeningeal and subarachnoid meningeal vessels, brainstem, and cerebellum. The cognition also was more extensively studied in ATTRV30M. The cognitive impairment was described in liver transplanted patients, in patients with long-standing disease, and in carriers of ATTRV30M mutation in the asymptomatic phase. Despite the description of cognitive dysfunction in ATTRv amyloidosis, there is no previous study associating cognition and brain MRI findings in this population. **Objective:** To examine brain characteristics (volume and cortical thickness) and their association with neuropsychological measures in ATTRv patients. **Methods:** An observational study of a sample of 21 patients (mean age: 42.5±9.7 years) with genetic confirmation of TTR mutation was conducted. All patients were submitted to an extensive neuropsychological assessment and brain MRI. T1-weighted images were automatically segmented in the FreeSurfer software. Patients were sorted into two groups according to cognitive dysfunction: (1) ATTRv normal cognition and (2) ATTRv cognitive dysfunction. **Results:** Fourteen ATTRV30M (p.V50M) and seven ATTRV122I (p.V142I) patients participated in the study. Thirteen ATTRv patients (43.6±8.9 years) presented neurocognitive dysfunction. Neuropsychological evaluation showed memory dysfunction in ten patients. Seven patients presented dysfunction in visuospatial ability. Executive functions were impaired in four patients. Cognitively dysfunctional ATTRv patients presented lower cortical thickness compared with cognitively normal patients in the following regions: lingual gyrus, left pericalcarine cortex, right precentral gyrus, right supramarginal, and right transverse temporal. The lingual gyrus was strongly correlated with memory (RAVLT, delayed recall) and executive function task (TMT B). Memory was also correlated with the left pericalcarine and right precentral gyrus. The right supramarginal gyrus correlated with attention (TMT A). **Conclusion:** This study suggests that cortical thickness can be associated with cognitive dysfunction in ATTRv amyloidosis. Cortical regions such as the lingual gyrus, right precentral gyrus, and left pericalcarine cortex were correlated with cognition in individuals with cognitively dysfunctional ATTRv amyloidosis.

Correspondence: Lucas Gondim Briand Vieira; Email: lucasbriand@hotmail.com.

Background: Charcot-Marie-Tooth (CMT) disease and related neuropathies pose diagnostic challenges due to genetic heterogeneity and overlapping clinical and electrophysiological features. **Objective:** We used a machine learning model, RandomForestClassifier, to classify CMT subtypes based on clinical and electrophysiological data. **Methods:** Data were obtained from 54 patients with genetic confirmed CMT, including CMT1A, CMT1B, males with CMTX1 and CMT4C subtypes. The dataset included: sex, age of onset, and electrophysiological measurements. Missing values were imputed with the median of the corresponding class. The target variable, diagnosis_class, was mapped to four categories: CMT1A, MPZ, GJB1, and SH3TC2. The dataset was split into training (80%) and test (20%) sets, stratified by diagnosis_class. SMOTE was used to address class imbalance. A RandomForestClassifier was trained on the resampled training set. Model performance was evaluated using accuracy, precision, recall, F1-score, and ROC-AUC. Optimizations included setting the number of trees to 75, maximum depth to 10, minimum samples to split to 5, and minimum samples at a leaf to 2, aiming to enhance performance and reduce overfitting. **Results:** The optimized model achieved an accuracy of 95% on the test set. Precision, recall, and F1- scores were: CMT1A (precision 1.00, recall 0.80, F1-score 0.89), MPZ (1.00), GJB1 (1.00), and SH3TC2 (precision 0.83, recall 1.00, F1-score 0.91). The confusion matrix showed minimal misclassification, primarily in CMT1A. Feature importance analysis revealed that ulnar conduction velocity, age of onset, and median nerve latency were the most significant predictors. **Conclusion:** The optimized RandomForestClassifier demonstrates high accuracy in classifying demyelinating CMT subtypes, with excellent performance for MPZ and GJB1. The model shows limitations in distinguishing between CMT1A and SH3TC2 subtypes, suggesting further refinement with additional data and feature engineering. This study highlights the potential of machine learning models in aiding the diagnosis of genetically and clinically heterogeneous neuropathies.

Exploring how cognitive components influence social cognition in patients with dementia

Lucas de Andrade Saraiva[1], Dreicy Helen de Souza Rodrigues[1], Ana Laura Daldegan[1], Viviane Amaral Carvalho[1], Larissa de Souza Salvador[1], Luciano Inácio Mariano[1], Vinícius Tinarelli Silva[1], Paulo Caramelli[1], Elisa de Paula França Resende[1], Leonardo Cruz de Souza[1]

[1]Universidade Federal de Minas Gerais, Belo Horizonte MG, Brazil.

Correspondence: Lucas de Andrade Saraiva; Email: lucasdeandradesaraiva@gmail.com.

Background: Social cognition involves a complex set of mental abilities related to perceiving, processing, interpreting, and responding to social cues. These skills enable people to behave appropriately in various social settings. Social cognition includes essential skills such as recognising facial expressions, understanding others' perspectives (theory of mind), social reasoning, moral judgment, and decision-making. **Objective:** This study aims to investigate how different elements of cognition may influence the social cognition of patients with dementia, specifically those with AD and FTD. **Methods:** We included two groups of participants: 1) FTD (n=19, 11M/8F; mean age=63.7±9.8 years; mean schooling=11.7±5.4; Disease Duration:4.1±2.4; MMSE=23.0±6.2); and 2) AD (n=25; 9M/16F; mean age=69.8±10.4 years; mean schooling=9.2±5.6; Disease Duration:6.31±5.1; MMSE=22.1±4.0). All participants underwent a comprehensive cognitive assessment using the following tests: Craft Story 21, The Beson Complex Figure Test, Digit Span test, Semantic Verbal Fluency, Trail Making Test, The Multilingual Naming Test (MINT) and Phonemic Verbal Fluency (P and M). The neuropsychiatric symptoms were evaluated using the Neuropsychiatric Inventory (NPI). Social cognition was assessed with Mini-Sea (Faux-Pas and Ekman test). **Results:** Patients with FTD performed statistically better than the AD group in cognitive tests assessing immediate memory, visuoconstructive function, processing speed, and executive functions. When assessing the cognition elements that could affect the social cognition of patients with dementia, it was found that both patients with FTD and those with AD showed a positive correlation between social cognition and various cognitive functions. These included working memory and attention (Digit Span test), semantic memory (MINT test), and language skills (animal category fluency and phonemic verbal fluency). Additionally, both groups of dementia patients displayed a negative relationship between social cognition and the time it took to complete the Trail Making Test, which is linked to processing speed and executive functions. On the other hand, when evaluating the differences between both groups, it was possible to identify that the social cognition of patients with AD, unlike patients with FTD, showed a positive correlation with visuoconstructive functions (Beson Complex Figure) and a stronger correlation with language (not only animal category but also vegetable category fluency). Additionally, it is worth noting the negative correlation between the neuropsychiatric symptom agitation (NPI) and social cognition in the AD group. **Conclusion:** The study highlights the complex relationship between cognitive functions and social cognition in patients with dementia, emphasising the need to consider specific cognitive profiles and neuropsychiatric symptoms when assessing social cognition for tailored interventions and support strategies.

Exploring ITPR3 mutations in Charcot-Marie-Tooth neuropathy: a case report from Brazil

Gabriel Thomaz Candido[1], Carolina Braga Moura[1], Leonardo Sena de Souza[1], Ana Luiza Morgado[1], Maria Clara de Oliveira Lemes[1], Helena do Amaral Barreto[1], Camila Castelo Branco Pupe[1], Osvaldo Jose Moreira do Nascimento[1]

[1]Universidade Federal Fluminense, Niterói RJ, Brazil.

Correspondence: Gabriel Thomaz Candido; Email: gabriel_candido@id.uff.br.

Case presentation: A 25-year-old patient presents with a history of scoliosis diagnosed at 19 and torsion of the thoracic vertebra following a car accident at 25. Since then, he has experienced chronic lumbar pain radiating to the left leg, worsening during the pandemic. Currently, he reports acute pain on the left side and had difficulty walking due to lower limb weakness. Medications for pain management include tramadol, Amytril, Pregabalin, Reconter, Restiva, and Frontal. Physical examination reveals symmetrical muscle strength, reduced sensitivity in distal limbs, and normal coordination. According to the MRC scale, he presents grade 4 for wrist extension, finger extension, finger abduction, thumb opposition, and hip flexion; grade 3 for knee flexion and knee extension; grade 2 for ankle dorsiflexion. Bilateral peroneal atrophy, flat feet, and hammer toes are observed. Hyporeflexia in biceps, triceps, and brachioradialis tendons, and areflexia in patellar and Achilles tendons. Reduced sensitivity to pain, temperature, touch, and vibration in the distal portions of both upper and lower limbs. Nerve conduction study shows sensory-motor axonal and distal predominant polyneuropathy affecting all four limbs with predominance of the lower limbs. There is a mild reduction in conduction velocities of the median, ulnar, tibial, and sural nerves, with reduction in the amplitudes of the sural nerve potentials. Study of F waves shows borderline values of minimum latency of the median and tibial nerves. Electromyography reveals increased motor unit amplitudes and neurogenic recruitment in the distal muscles of the lower limbs. Genetic testing reveals a variant of uncertain significance (VUS) was found in heterozygosity in the ITPR3 gene, revealing a rare mutation. **Discussion:** The pathogenesis of ITPR3 mutations involves dysregulation of Ca2+ signaling pathways, disrupting mitochondrial function, ER-mitochondrial Ca2+ transfer, and cellular homeostasis. These molecular mechanisms contribute to the neuropathic phenotype observed in CMT patients with ITPR3 mutations. This case highlights the significance of genetic testing in diagnosing rare neuropathic conditions and underscores the emerging role of ITPR3 in CMT neuropathy. Understanding the molecular mechanisms underlying CMT pathogenesis may pave the way for novel therapeutic interventions targeting Ca2+ flux dysregulation. Further research is warranted to elucidate the functional consequences of ITPR3 variants and explore potential therapeutic targets for CMT. **Final comments:** Although the ITPR3 mutation appeared as VUS, the clinical phenotype is classical for CMT. Further research is needed to elucidate the functional consequences of ITPR3 variants and explore its pathophysiology for CMT as a new form of the disease.

Exploring the medication use: a comparative study of HTLV-1 patients facing HAM/TSP and those without

Ana Flávia Novaes[1], Davi Tanajura Costa[1], Fernanda Khouri Barreto[1], Qesya Rodrigues Ferreira[1], Carolina Souza Santana[1], Jéssica Oliveira de Souza Nascimento[1], Ariana Leal Borges da Cruz[1], Alice Palmeira Nascimento Cerqueira[1], Felipe de Oliveira Andrade[1]

[1]Universidade Federal da Bahia, Vitória da Conquista BA, Brazil.

Correspondence: Ana Flávia Novaes; Email: anaflavia635@gmail.com.

The human T-cell lymphotropic virus type 1 (HTLV-1) is a retrovirus capable of infecting human cells and causing severe diseases such HTLV-1-associated myelopathy/tropical spastic paraparesis (HAM/TSP) that is an inflammatory disease of the central nervous system, with symptoms typically appearing in the fourth decade of life. The symptoms manifest as spasticity, neurogenic bladder, and chronic pain. Due to its late onset, it can be associated with other comorbidities in the individual. Thus, the use of different classes of medications may be common among patients with neurological symptoms. This study aims to describe the medication use of patients infected by HTLV-1 with or without HAM/TSP. This cross-sectional study was carried out with patients living with HTLV-1 who are assisted at an HTLV-1 reference center in Bahia, Brazil, from March 2023 to May 2024. Data were obtained by analyzing medical records and during neurological examination. The statistical significance analyses were

performed using Fisher's exact test with SPSS software v. 27. A total of 110 patients were evaluated, 82 (84.5%) of whom were classified as non-HAM/TSP and 28 (25.4%) as HAM/TSP. The mean age of the patients classified as non-HAM/TSP was 48.66±16.78 years, of which 65 (80%) were female. The mean age of the HAM/TSP patients was 56.46±19.75 years, of which 21 (75%) were female. The use of lipid-lowering therapy was higher in the HAM/TSP group (7 or 25%), thyroid drugs (3 or 10%), and antihypertensives (11 or 39%). On the other hand, antidiabetics were more prevalent in non-HAM/TSP group (9 or 10%). No statistical difference between the groups was observed. It is important to note that among the most commonly used medications by the study group, antidepressants were used by the majority of them (11 out of 28 patients), ($p<0.01$). Depressive disorder in people living with HTLV-1 or HTLV-2 can be a primary or secondary consequence of the infection, so it should be evaluated individually, as it is known that the psychological profile of patients can influence their therapeutic process. The HAM/TSP group also reported higher use of analgesics (5 or 17%) with statistical differences between groups ($p<0.01$). This may lead to reflection on untreated neuropathic pain, self-medication, and, primarily, pain as a cardinal symptom in patients living with myelopathy. The data reveal that patients with neurological involvement associated with HTLV-1 infection have a diverse medication profile, offering insights into associated comorbidities like the use of lipid-lowering agents. The increased use of antidepressants highlights the often overlooked psychological impact faced by these patients. The notable difference in analgesic usage underscores the crucial need for effective pain management, especially for the neuropathic pain they experience.

Exploring transient global amnesia: insights from demographic, clinical, cognitive and neuroimaging profiles

Ana Luiza Figueiredo Campos, Marina Isoni Martins[1], Paolla Giovanna Rossito de Magalhães[2], Antonio Jaeger[1], Rachel Laguardia Rego[2], Bárbara Cristina Silveira de Oliveira[2], Aretha Miranda Silva[2], Vinícius Canhestro Roedel[2], Augusto Antunes[3] , Leonardo Cruz de Souza[1]

[1]Universidade Federal de Minas Gerais, Belo Horizonte MG, Brazil.
[2]Hospital Madre Teresa, Belo Horizonte MG, Brazil.
[3]Axial Metódos de Imagem, Belo Horizonte MG, Brazil.

Correspondence: Ana Luiza Figueiredo Campos; Email: aninhaalfc8@hotmail.com.

Background: Transient global amnesia (TGA) manifests as a sudden onset of anterograde amnesia without other neurological deficits, typically lasting 2 to 24 hours, and resolving spontaneously. Its estimated incidence in the general population is 5-10 cases per 100,000 people per year. However, there is a scarcity of studies investigating TGA in the Brazilian population **Objective:** To characterize the demographical, clinical, cognitive and neuroimaging features in a series of consecutive TGA patients. **Methods:** This longitudinal and translational study focuses on patients presenting with TGA symptoms seeking emergency neurological care. Inclusion criteria encompass patients exhibiting cognitive impairments limited to episodic memory, validated by an external observer. All patients underwent the Brief Cognitive Battery (including the Mini-Mental State Examination [MMSE] and the Figure Memory Test for episodic memory), and the Facial Emotion Recognition Test (FERT), which assesses seven emotions: happiness, sadness, fear, disgust, surprise, anger, and neutral. Results from the TGA group were compared with data from cognitively health controls (n=20) matched for age, sex and education. **Results:** A total of 28 patients were included in the study, comprising 18 women and 10 men, with a mean age of 59.2 years. Medical history revealed that 45.83% had systemic hypertension, 25% had obstructive sleep apnea, and 16.7% had migraine. None of the participants had a prior history of stroke, intracranial hemorrhage, or epilepsy. Regarding potential triggering events, 37.5% of patients cited emotional stress, 16.7% Valsalva maneuvers, 8.3% sexual activity, while 16.7% denied any specific triggering events. Compared to controls, TGA patients had lower scores on the MMSE ($p<0.0001$), on the immediate memory ($p<0.0001$), delayed recall ($p<0.0001$) and in the recognition scores ($p<0.0001$). Patients did not differ from controls in the recognition of facial emotions (total score) or in the subscores of each emotion. Brain MRI was conducted on 24 patients, revealing bilateral high-signal abnormalities in the hippocampus on DWI in 20% patients, high-signal abnormalities in the right hippocampus in 30% patients, and in the left hippocampus in 15% patients. No signal abnormalities were observed in 35% patients. **Conclusion:** While clinical and cognitive data are homogeneous among patients, neuroimaging findings are heterogeneous, with different patterns of hypersignal. Patients have spared recognition of facial emotions. These findings highlight the strict memory involvement that characterizes TGA. Longitudinal follow-up studies are essential to deepen our understanding of the underlying pathophysiological mechanisms and the long-term cognitive outcomes in TGA patients.

Explosive onset of non-epileptic seizures following levetiracetam introduction – is there a possible association

Cássia Elisa Marin Dapper[1], Gislaine Baroni[2], Rudá Alessi[2], Eliseu Paglioli[2], André Palmini[2], William Alves Martins[2]

[1]Universidade de Caxias do Sul, Caxias do Sul RS, Brazil.
[2]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Cássia Elisa Marin Dapper; Email: cassiaemarin@gmail.com.

Case presentation: A 14-year-old female high school freshman began neurological evaluation at our institution in 2019 following episodes of unconsciousness that began at age 7, characterized by unilateral head deviation, occasional generalized tonic-clonic movements, and tongue biting. She was diagnosed with epilepsy and effectively managed with oxcarbazepine, reducing seizures to less than one per year. In October 2018, a breakthrough seizure prompted a switch from oxcarbazepine to levetiracetam (LEV), considering her age and reproductive stage. Subsequently, her seizures evolved into episodes marked by disconnection, excessive salivation, ocular deviation, and rotational head and hip movements lasting up to five minutes. These episodes increased in frequency, often triggered by anxiety-provoking situations. Her parents noted new behavioral changes including irritability, impatience, inattention, and forgetfulness affecting both home and school life, leading to conflicts with her father. Her medical history included a term cesarean birth with nonconsanguineous parents, neonatal hypoglycemia, and a 14-day hospitalization at four months due to suspected metabolic issues and poor weight gain. Until age six, she experienced recurrent unexplained vomiting episodes that resolved without a definitive diagnosis. Childhood was generally peaceful with good academic performance, though occasional disagreements occurred with her mother and sister; she had a closer relationship with her father. Family history included only a paternal aunt with childhood febrile seizures. A 72-hour video-EEG captured three typical events during wakefulness characterized by vertical ocular deviation, blinking, ocular flutter, and irregular head and limb movements progressing to spitting movements lasting about six minutes. No corresponding EEG abnormalities were observed. Brain MRI findings were normal. A diagnosis of psychogenic nonepileptic seizures (PNES) was established, leading to referral for psychiatric assessment. LEV was discontinued, and oxcarbazepine was reintroduced gradually up to 1200mg daily, resulting in progressive improvement of PNES over subsequent months. **Discussion:** PNES and epileptic seizures (ES) can coexist in up to 5-60% and be a diagnostic and therapeutic challenge. In addition, patients with epilepsy have a close association with behavioral, psychiatric and developmental disorders, which may be influenced by anti-epileptic drugs effects. Behavioral side effects of LEV have been frequently reported, including aggression as well as change mood states such as depression, agitation, irritability and hyperexcitability. Furthermore, some recent published papers showed a possible association of LEV use and occurrence of PNES. **Final comments:** Our case highlights the possibility of explosive PNES onset after treatment with LEV in patients with no previous functional disorders. Such condition must be kept in mind with severe worsening of seizures upon introduction of LEV.

Expression of cellular pluripotency regulated micrornas associated with tumor recurrence in meningiomas

Liliane Cristina da Silva[1], Victor Cunha Tirapelli[1], Ana Laura Ribeiro e Silva Stevanato[1], Janaina Regina Léllis[1], José Guilherme Marques Farinha[1], Mariana Matheus Pupin[1], Fernanda Maris Peria[1], Carlos Gilberto Carlotti Jr[1], Mucio Luiz de Assis Cirino[1], Daniela Pretti da Cunha Tirapelli[1]

[1]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: José Guilherme Marques Farinha; Email: zeguifarinha@hotmail.com.

Background: The expression of miRNAs is associated with a variety of diseases, including neoplasms. In recent years, a large number of abnormally expressed miRNAs have been shown to be effective in understanding the oncogenesis, development, progression and prognosis of meningiomas. Furthermore, it is known that miRNAs act as oncogenes or tumor suppressors and that they regulate essential molecular pathways such as transcription factors involved in the pluripotency phenotype of stem cells. Overexpression of these transcription factors is associated with metastatic formation and tumor recurrence in many types of tumors, including meningiomas. **Objective:** Therefore, our aim was to analyze the expression of microRNAs miR- 34a, miR-145 and miR-221 that regulate the pluripotency pathway of stem cells and correlate with tumor recurrence in grade I meningiomas. **Methods:** We used 30 samples, belonging to 15 patients who presented relapse of grade I meningiomas. **Results:** We observed low expression levels of miR-34a in the group of tumor relapses when compared to the groups of control individuals and primary tumors, which may be associated with the role of tumor suppressor of this miR. The miR-145 also showed a decrease in expression levels observed between the control group and the group of tumor recurrences. We also observed a decrease in miR-145 between the groups of the control group and the group of primary tumors. miR-221 did not differ between the groups studied.

https://doi.org/10.5327/CBN240787

Expression of micrornas: miR-27A, miR-636, miR-1229 associated with memory in tonsils, hippocampus and blood of patients diagnosed with epilepsy

Adriana Lis Pereira[1], Victor Cunha Tirapelli[1], Lucas Cunha Tirapelli[1], José Guilherme Marques Farinha[1], Janaína Regina Lellis[1], Maria Julia Nunes[1], Jairo Pinheiro da Silva[1], Carlos Gilberto Carlotti Junior[1], Mucio Luiz de Assis Cirino[1], Daniela Pretti da Cunha Tirapelli[1]

Correspondence: José Guilherme Marques Farinha; Email: zeguifarinha@hotmail.com.

Background: Epilepsy is a chronic disease of the central nervous system (CNS), which generates neurobiological, cognitive and psychosocial consequences. The most common type of focal epilepsy is temporal lobe epilepsy with hippocampal sclerosis, characterized by cell loss and gliosis in the hippocampus and amygdala. Several studies have demonstrated the presence of memory deficits in patients with difficult-to-control epilepsy. However, little is known about the molecular aspects involved in the process of changes in the cognitive function of patients with epilepsy. In this context, current literature has demonstrated that small RNA molecules called microRNAs can regulate molecular pathways important in epileptogenesis. Therefore, identifying possible modulation of molecular targets associated with memory by microRNAs can contribute to the development of new therapeutic approaches as well as tools that help in the diagnosis and prognosis of the disease. Temporal lobe epilepsy has been associated with cognitive dysfunctions, especially short- and long-term memory disorders. Many studies have demonstrated the presence of memory deficits in difficult-to-control epileptic patients. Our hypothesis is that regulatory microRNAs of molecular targets associated with memory may be involved in the prognosis of drug-resistant patients after surgical treatment. **Objective:** To analyze the expression of microRNAs: miR- 27a, miR-636, miR-1229 that control targets associated with memory in tonsils, hippocampus and blood of patients diagnosed with epilepsy. **Methods:** Hippocampus and blood samples from 20 patients with TLE were collected, 10 with good postoperative evolution (Engel I) and 10 with unsatisfactory postoperative evolution (Engel III and IV). Hippocampal tissue from deceased individuals and blood from healthy individuals were used as controls. The expression analysis of the miRNAs was performed using the RQ-PCR technique. **Results:** The microRNA-27a was differentially expressed between the control group and the epilepsy group both in the hippocampus and in the blood. However, the same was not observed in the tonsils. It was also differentially expressed between Engel I and III and IV both in the blood and in the tonsils and hippocampus. However, the expression pattern was inverse, that is, in the tonsils, miR-27a showed higher expression levels in the control group when compared to the epilepsy group and in the hippocampus and in the blood, the expression levels of this microRNA were higher in the epilepsy group. MicroRNA-636 was differentially expressed by observing the Engel classification in hippocampus. microRNA-1229 was not differentially expressed between the groups studied in tonsils.

Correspondence: Talita Guimarães Balieiro; Email: talitagbalieiro@gmail.com.

Background: MicroRNAs (miRNA) are small, double-stranded RNAs and post-transcriptional modulators of gene expression, which control the expression of messenger RNAs (mRNAs) by binding to complementary sequences, causing gene silencing. Aberrant miRNAs have been extensively studied regarding their diagnostic and prognostic value for various diseases. In this study, we sought to assess the expression patterns of miR-19b and miR-7 in serum samples from patients with REM sleep behavior disorder (RBD), a condition characterized by dream enactment during REM sleep due to loss of muscle atonia. The progression of idiopathic RBD to Parkinson's disease (PD) and Dementia with Lewy Bodies underscores its significance as a clinical indicator of the early stages of these synucleinopathies. Studies reveal that miR-19b levels are altered in patients with RBD. The altered expression of miR-19b occurs years before the onset of motor symptoms, suggesting its potential as an early biomarker for the prodromal phase of these disorders. The miR-7 has been implicated in the underlying mechanisms of PD, including the regulation of alpha-synuclein, dopaminergic cell death and neuroinflammation. **Methods:** The samples were collected from patients participating in the PROBE-PD - Epidemiological Study on Established and Prodromal Parkinson's Disease in Brazil Project (Candangolândia, Distrito Federal) and processed in the Technology for Gene Therapy Laboratory - Research Center for Major Themes (University of Brasilia). Peripheral venous blood from 6 controls and 6 patients with RBD was collected by a standardized procedure with serum collection tubes. After 30 minutes were centrifuged at 2000 xg for 10 min and maintained at 4°C. Following, in a safety cabin the serum was dispensed in aliquots into 2 mL cryovials and stored at -80°C. The extraction was performed using a commercial kit (miRNeasy Serum/Plasma Advanced) and quantified using Qubit (Invitrogen). The RT-qPCR reaction was performed with commercial kits for microRNA (TaqMan Advanced miRNA cDNA Synthesis and TaqMan Advanced miRNA Assays) and calibrated with miR-39-3p. Data analysis was performed based on the relative expression of delta delta Ct (2^-ΔΔCT). The GraphPAD Prism 9 software was used for statistical analysis. **Results:** The qPCR analysis revealed an increased expression of miR-19b and miR-7 in patients with probable RBD compared to the control group. Specifically, miR-19b and miR-7 exhibited fold increases of 7.206 (P=0.1647; t-test) and 8.890 (P=0.1694; t-test), respectively, in RBD patients. **Conclusion:** The observed trend towards increased expression of these microRNAs suggests that miR-19b and miR-7 are potential biomarker candidates for patients with RBD. The study is ongoing, with additional samples being analyzed to further assess the accuracy of miR-19b and miR-7 as biomarkers for PD.

Background: The importance of visual perception in sports performance is crucial, especially in high-speed sports like soccer. Professional athletes develop specific visual skills enabling rapid and accurate processing of information. Effective visual perception is pivotal for good performance in soccer. The eye-tracking (ET) technique offers insights into how athletes visually explore the playing field, providing a deeper understanding of the specific visual skills necessary for success. **Objective:** To compare the pattern of eye movement in soccer athletes, assessing the speed and efficiency with which athletes process visual stimuli and how variations in movement patterns influence decision-making during a soccer match. **Methods:** In a randomized double-blind study, professional soccer players from three teams (A, B, and C), N=63, aged 18 to 21 and older, underwent ET tests using the Dx100 system. Vergence Pursuit Test: Each athlete followed a target moving towards and away from them. Saccade Test: Participants fixed their gaze on a point while a visual stimulus appeared in different positions. Smooth Pursuit Test: Players followed a point moving in specific directions (horizontal or vertical). Optokinetic Test: The eye movements were recorded and analyzed to assess coordination in response to the optokinetic stimulus. **Results:** 1. Team's performance Saccade Horizontal and Vertical: Teams A, B, and C showed latency values below the normal limit (<220msec) and precision within the normal range. 2. Team's performance Saccade and Reaction Time: Team A had a saccade latency time of 216 msec, while Team B had 203 msec, both within normal limits for motor reaction time. 3. Smooth Pursuit Horizontal and Vertical: All teams showed gains within normal limits for low frequencies. Teams A and B also showed gains at higher frequencies. 4. Teams' performance, Optokinetic, 20 and 60 deg/sec: Teams showed visual tracking gains above normal at 20 deg/sec, but below normal at 60 deg/sec. Goalkeepers showed better performance than defenders. 5. Teams' performance, Subjective Visual Vertical: Teams A and B showed negative deviations, while Team C showed a positive deviation. Good visual response speed is essential for decision-making, with no significant differences between teams and the control group. Difficulties with high-speed stimuli were noted, highlighting a moderate capacity for visual tracking. Competitive athletes may show better results, indicating the need for further research. **Conclusion:** Eye-tracking provides a comprehensive analysis of eye movements in soccer athletes. Tests revealed positive results compared to normal limits, with goalkeepers showing better performance than defenders. Differentiated training benefits visual skills, and further studies are necessary to confirm results.

Fabry disease, a diagnostic challenge: case report

Yasmin Ramalho Mandarino[1], Luana Cristina Stefanes[1], Mariana Moreira Alves[1], Pietra Cani Linzmeier[2], Natália Cardoso Darabas[2], Hannah Bang[2], Maria Eduarda Angelo de Mendonça Fileti[2], Thábata Emanuelle Martins Nunes[2], Carla Heloísa Cabral Moro[2], Alexandre Luiz Longo[2]

[1]Universidade da Região de Joinville, Joinville SC, Brazil.
[2]Hospital Municipal São José, Joinville SC, Brazil.

Correspondence: Yasmin Ramalho Mandarino; Email: yasminramalhoo@gmail.com.

Case presentation: A 17-year-old male patient visited the neurology emergency room due to intermittent loss of vision in his left eye. No abnormalities were found in the head CT and in the initial lab work, but an intraconal infiltrative lesion was detected on the MRI. He had a history of orbital pseudotumor in the right eye, diagnosed the

previous year. The patient reported ongoing follow-up with a rheumatologist for chronic pain in the axial joints since the age of 12, without a defined diagnosis, and abdominal pain and diarrhea after consuming dairy products. The family medical history didn't present relevant findings. Physical examination revealed optic disc atrophy in the right eye and optic disc stasis in the left eye, with visual acuity of 20/20 in the left eye and blindness in the right eye, with no other abnormalities. The orbital MRI revealed signal alteration and atrophy of the posterior intra-orbital, prechiasmatic, and chiasmatic segments of the right optic nerve, appearing as sequelae, with no changes in the left orbit. Laboratory tests showed alpha-galactosidase activity of 0.32µmol/L/h and lyso-Gb3 biomarker levels of 46.4ng/mL, with no other alterations. Based on these findings, a diagnosis of Fabry disease was made. Genetic sequencing of the GLA gene revealed the presence of a pathogenic variant in homozygosis described as cys142Arg, associated with alpha-galactosidase A deficiency. During the hospital stay, the patient was prescribed pulse therapy and presented complete resolution of the new symptoms. Optic nerve biopsy showed no abnormalities. The final diagnosis was orbital pseudotumor due to Fabry disease. Enzyme replacement therapy was indicated. The patient continues to be monitored with cranial and orbital MRI. The clinical condition has remained stable since. **Discussion:** Fabry disease is an X-linked disorder caused by a mutation in the gene encoding the lysosomal enzyme Alpha-Galactosidase-A, responsible for breaking down neutral glycosphingolipids and globotriaosylceramide in lysosomes. It progressively damages vital systems such as the heart, kidneys, and nervous system, due to systemic accumulation of these substances in tissues. This progressive buildup causes cellular dysfunction and can result in secondary inflammation or fibrosis. Fabry disease is rare, with a frequency of 1 in 40,000 in men and 1 in 117,000 in women. The pathophysiological link with the abnormal metabolism of glycosphingolipids is unclear and requires further studies to be elucidated. **Final comments:** Fabry disease is a rare genetic disorder that challenges diagnosis due to its heterogeneous presentation. In the typical form, symptoms generally begin around the age of 10, being the average age of diagnosis usually around 28. Early diagnosis is essential.

Facial diplegia, sixth nerve palsy and hyperreflexia: rare variant of Guillian-Barré syndrome and response to plasmapheresis

Cássia Elisa Marin Dapper[1], William Alves Martins[2]

[1]Universidade de Caxias do Sul, Caxias do Sul RS, Brazil.
[2]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Cássia Elisa Marin Dapper; Email: cassiaemarin@gmail.com.

Case presentation: A 55-year-old man presented with a 2-week history of diplopia, facial paresis, and gustatory alterations. An upper airway infection had occurred two days before the onset of symptoms but resolved before admission. His previous medical history was unremarkable. Neurological examination revealed partial left sixth nerve palsy along with complete facial diplegia (House-Brackmann grade VI), so severe that it prevented him from closing his eyes, resulting in a bilateral Bell's sign. He was also unable to purse his lips. Deep tendon reflexes were brisk and symmetric in all limbs, but the plantar response was flexor. There were no weakness or any sensory symptoms, despite gustatory dysfunction. Cerebrospinal fluid (CSF) examination showed slightly elevated protein (48mg/dl) and a normal cell count (1 leukocyte/mm^3). Brain MRI revealed bilateral seventh nerve enhancement without any other lesions. Rheumatologic tests, cancer screening, and other studies were normal. Serologic tests showed no signs of Campylobacter jejuni or Borrelia burgdorferi infection. EMG demonstrated bilateral seventh nerve injury with severely reduced motor conduction amplitude (0.03mV on the left and 0.04mV on the right) and normal latency (3.85ms). Administration of methylprednisolone (1g/day) for 5 days did not alleviate his symptoms. Antibodies against gangliosides (anti-GM1 IgM and anti-DT1a) were positive, leading to a diagnosis of a Guillain-Barré syndrome (GBS) variant. Treatment with plasmapheresis was initiated, and after five sessions, his ocular movement returned to normal and facial diplegia began to recover. Eight months later, he remains asymptomatic, with facial movements almost completely returned to normal (House-Brackmann grade II). **Discussion:** GBS encompasses a spectrum of autoimmune neuropathies, with variants such as Miller Fisher syndrome and acute motor axonal neuropathy presenting distinctive clinical features. Facial diplegia, observed in some GBS variants, manifests as bilateral facial weakness, potentially accompanied by other cranial nerve involvement and areflexia, complicating the presentation and requiring prompt differentiation from other etiologies to initiate immunomodulatory treatments like IVIG or plasmapheresis, like in our case. Hyperreflexia is uncommon, nonetheless brisk reflexes might occasionally be observed early in the disease course or in specific variants. Pathophysiology involves molecular mimicry where antecedent infections trigger an immune response that cross-reacts with peripheral nerve components, notably gangliosides, leading to demyelination or axonal damage. Comprehensive neurological examination, CSF analysis showing albuminocytologic dissociation, and electrodiagnostic studies, alongside serological tests for specific antibodies, are pivotal for accurate diagnosis and management, with recovery potential varying widely among patients based on the subtype and severity of nerve involvement.

Factors associated with intensive care unit admission for patients with acute stroke: a cohort study in a reference hospital in Bahia

Luiz Paulo Oliveira Martins[1], Gabriel Souza Medrado Nunes[1], Maria Eduarda Messias Vassoler[1], Milena Fernandes de Oliveira[1], Gabriel Teles de Oliveira Piñeiro[1], Thaís Barbosa de Oliveira[1], João Pedro Fernandes Gonçalves[1], Pedro Antonio de Jesus[1]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.

Correspondence: Luiz Paulo Oliveira Martins; Email: luizpom2000@gmail.com.

Background: Intensive care unit (ICU) admission is common for patients in need of continuous monitorization. Physicians often need to assess whether patients with acute neurological injuries require ICU admission. However, the factors associated with ICU admission are not well explored in hospitalized stroke patients. **Objective:** To investigate clinical and laboratory factors associated with ICU admission in acute stroke patients. **Methods:** This study enrolled patients with acute stroke admitted to a referral stroke unit in Bahia, between July/2023 and March/2024. Clinical and epidemiological characteristics were extracted from patients' medical records or obtained through personal interviews. The initial National Institutes of Health Stroke Scale (NIHSS) was obtained through physician assessment during admission. Thrombolysis was defined as the administration of alteplase noted in medical records. Uremia and thrombocytopenia at admission were defined by levels of urea above 50mg/dl and platelets count below 150x109/L, respectively. The Mann-Whitney and Chi-Square tests were employed to evaluate associations. **Results:** The study included 213 patients, 51.2% of whom were female and the median age was 66.3 years (IQR: 59-74.3). During the hospitalization period, 20 patients (9.4%) were admitted to the ICU. Regarding comorbidities, 78.95% had hypertension, 36.2% had diabetes and 27.7% had dyslipidemia. Among all patients, the median NIHSS at admission was 7 (IQR: 4-12). In general, higher NIHSS values were associated with ICU admission ($p<0.05$). Thrombolysis was performed in 87 patients (40.8%) and its occurrence was not significantly associated with ICU admission ($p>0.05$). The mean urea value and platelets count were 35.8 ± 16.5 mg/d and 215x109±101x109/L, respectively. Uremia was diagnosed in 14 patients (6.6%), showing a significant risk of ICU admission ($p<0.05$; OR 4.00; 95% CI: 1.11 – 14.43), while thrombocytopenia was diagnosed in 28 patients (13.1%) and also presented a significant risk of ICU admission ($p<0.05$; OR 3.94; 95% CI: 1.37 – 11.30). **Conclusion:** Our cohort study identified no significant association between thrombolysis and ICU admission in acute stroke patients. However, higher NIHSS scores, uremia, and thrombocytopenia were all significantly linked to increased ICU admission rates. This identification may serve as early warning signs for adverse outcomes. By recognizing these clinical and laboratory factors, healthcare providers can promptly intervene, potentially preventing the progression to severe complications and the need for ICU admission. However, more comprehensive research is needed to better understand these associations.

https://doi.org/10.5327/CBN240793

Fahr's syndrome: a case report

Maria Carolina Marçon Barroso[1], Laura Alonso Matheus Montouro[1], Matheus Vieira Santili[1], Letícia Raiane Fogari[1], Ana Luíza Duran Casseb[1], Marina de Carvalho Bofo[1], Carolina Mendes Rahal[1], Cibele Alexandra Ferro[1]

[1]Faculdade de Medicina de Catanduva, Catanduva SP, Brazil.

Correspondence: Maria Carolina Marçon Barroso; Email: barrosomariacarolina@gmail.com.

Case presentation: Male patient, 75 years old, was admitted due to the first bilateral clonic tonic seizure associated with sialorrhea. On the previous day, reported epigastric discomfort, excessive sweating and lipothymia – followed by postictal confusion. Brain CT with calcifications bilaterally and symmetrically affecting the semioval centers, basal ganglia, thalamus, and dentate nuclei. Laboratory tests were normal. He was discharged a few days later with a prescription for valproic acid 500mg, without adherence. One year later, he returned to the emergency room with a new clinical condition of tonic-clonic seizure and Lamotrigine 100mg/day was initiated. He denies consanguinity. Deceased brother with unknown neurological disease. He denies chronic kidney disease, known previous neurological diseases and addictions. **Discussion:** Fahr syndrome is a rare neurodegenerative condition characterized by bilateral and symmetrical calcification of the basal ganglia, secondary to another pathology or familial association, an autosomal dominant inheritance, or idiopathic. Its main causes involve calcium metabolism, such as hypoparathyroidism, genetic diseases, and infections. The clinical condition is variable, there are behavioral and mood changes, movement disorders, balance disorders, headache, parkinsonism and seizures. The diagnosis is made through neuroimaging tests with a characteristic pattern and the investigation should include research for secondary causes. In this case, the patient presented with episodes of tonic-clonic seizures, one of the possible and nonspecific clinical manifestations of the disease. In the investigation, cranial tomography identified bilateral and symmetrical calcifications of the centrum semiovale, basal ganglia, thalamus and dentate nuclei, a characteristic finding of the syndrome. This diagnostic hypothesis was raised, proceeding with etiological investigation, due to its importance in the prognosis of the disease, because, in some cases, the calcifications have a good response to the treatment of the underlying cause. The main disorder to be investigated is hypothyroidism, diagnosed by reduced serum parathyroid hormone and calcium, and elevated phosphorus. In addition, other tests should be performed, such as TSH, T4, renal and hepatic function, HSR, CPK, ANA, VDRL, copper, ceruloplasmin, in order to rule out infectious and organic causes. After the investigation,

which proved to be normal, raising the diagnostic hypothesis of idiopathic or familial Fahr syndrome, suggesting research of other cases in the family. Treatment should be aimed at controlling symptoms or the underlying disease, if present, improving quality of life and preventing disease progression. **Final comments:** Its investigation begins after adequate anamnesis of neurological and clinical symptoms associated with characteristic neuroimaging. It is a syndrome with multiple etiologies associated with different clinical management and prognosis.

False negative genetic panel for spinocerebellar ataxias: a case report

Maiza de Oliveira Tenório[1], Lucas de Andrade Alexandre[1], Edvaldo Lucas da Costa Silva[1], Marcelo Palmares Oliveira e Silva[1], Paulo Felipe Bezerra Silva dos Santos[2], Amanda Sampaio de Sá[2], João Pedro Matos de Santana[1], Evelliny Gomes da Silva[1], Miriam Carvalho Soares[1], Marcos Eugênio Ramalho Bezerra[1]

[1]Universidade Federal de Pernambuco, Hospital das Clínicas, Recife PE, Brazil.
[2]Universidade Federal de Pernambuco, Centro de Ciências Médicas, Recife PE, Brazil.

Correspondence: Paulo Felipe Bezerra Silva dos Santos; Email: pfbsilva2@gmail.com.

Case presentation: Three sisters, aged 59, 62 and 65 years, were followed in an outpatient clinic of a public university hospital, due to a clinical presentation of slowly progressive imbalance and incoordination over a 10 years period. They reported similar cases in the family (father, paternal grandmother and paternal uncles). On physical examination, they presented dysmetria, dysdiadochokinesia and impaired tandem gait. Due to clinical suspicion, a panel for repeat expansions genes of spinocerebellar ataxias (SCA 1, 2, 3, 6 and 7) was performed in one of the sisters, with a negative result. Next gene sequencing was performed on the other two sister, with the following result: heterozygosity in the EEF2 gene (SCA26) present in two sisters and absent in the other, and heterozygosity in the CCDC88C gene (SCA40) present in two sisters and unknown in the other. As the diagnosis remained undefined, it was decided to perform, on the same patient with a previous negative panel, a molecular diagnostic test for SCA3, with a positive result this time: an allele with 20 repeats and another with 62 CAG repeats in the ATXN3 gene. Therefore, a presumed diagnosis was performed on the other sisters and a new genetic panel was requested for them. **Discussion:** The diagnosis of spinocerebellar ataxias is made based on clinical signs of progressive ataxia, family history, and positive genetic testing. Spinocerebellar ataxia type 3, known as Machado-Joseph disease, is the most common autosomal dominant subtype and results from the ATXN3 gene mutation, caused by a CAG repeat expansion on the long arm of chromosome 14. It presents a broad spectrum of manifestation, encompassing pyramidal symptoms, peripheral neuropathies, sleep disorders and oculomotor abnormalities. Currently, the definitive diagnosis is through a genetic panel capable of detecting the mutation causing the disease, which has an accuracy of around 99%. Rare diagnostic errors can occur due to rare mutations or polymorphisms. Other studies have already shown false negative results in cases of SCA, especially when there is a very high number of repetitions, in which the PCR technique shows 2 alleles that appear to have the same number of repetitions, in a normal quantity. In this case, the number of repetitions was not that high, but a false negative was also possible. Further investigations were compatible with SCA26 in two sisters and SCA40 in two other sisters, which are extremely rare subtypes of genetic ataxias. SCA 26 was described in the literature in a Norwegian family and SCA 40 in a Chinese family. As the result was divergent between patients from the same family and there was a similar clinical condition between them, it became important to review the investigation. **Final comments:** Even if the genetic panel yields negative results, due to the suggestive clinical condition, it should be considered for repetition, taking into account the possibility of a false negative result.

https://doi.org/10.5327/CBN240795

Familial amyloidosis with compound heterozygosity of the V122I and V30M: a case report

Matheus da Silva de Oliveira[1], Antônio Marcos Reissureição[1], Felipe Bento Michelato[1], Luís Fernando Fernandes Miranda[1], Yves Henrique Ramos Mansano[1], Pamella Francisquini Gardin[1], Ana Letícia Manso Assakawa[1], Isabela Kirach Gaio[1], Maria Júlia Costa Rocha[1], Gabriel Bortoli Ramos[2]

[1]Universidade Estadual de Maringá, Maringá PR, Brazil.
[2]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Matheus da Silva de Oliveira; Email: ra125466@uem.br.

Case presentation: The first case of Familial amyloidosis identified was a V122I/V30M compound heterozygosity. The first symptoms began at age of 50 with congestive heart failure and recurrent episodes of asthenia. After four years without a final diagnosis, the clinical condition progressed with neuropathic pain and proprioceptive dysfunction. The cardiac and neurological symptoms, associated with concentric hypertrophy of the heart identified by magnetic resonance imaging, raised the diagnostic hypothesis of amyloidosis, which was confirmed by pyrophosphate scintigraphy. Subsequently, a hereditary study was initiated through material extracted via oral SWAB for sequencing the TTR gene for Hereditary Transthyretin Amyloidosis. As a result of this study, 17 tests came back positive: nine individuals with heterozygosity for V122I variant, six for V30M and two with compound heterozygosity for V122I/V30M. **Discussion:** Transthyretin-associated amyloidosis is a genetic disease with autosomal dominant inheritance, caused by mutations in the TTR gene. Consequently, it commonly manifests in multiple individuals from the same family. The most significant aspect of the case is the identification of familial amyloidosis with 2 cases of compound heterozygosity for the V122I and V30M variants. Furthermore, the description of the first identified case allows the inference of which variant manifested first in the patient. The current literature describes the V122L variant as predominantly related to cardiac amyloidosis and reports the following main findings: cardiomegaly, conduction block, arrhythmia, anginal pain, congestive heart failure and sudden death. On the other hand, V30M is associated with amyloid neuropathy, whose main findings are: sensorimotor polyneuropathy, carpal tunnel syndrome, autonomic dysfunctions, possible evolution with cardiomyopathy, nephropathy and CNS symptoms. Although the V30M variant may progress to cardiomyopathy, this is not considered an initial finding. Therefore, it can be inferred that the V122I variant preceded its manifestations compared to the V30M variant. **Final comments:** Familial amyloidosis is a rare disease. The fact that the disease presents itself as a compound heterozygosity of V122I/V30M variants makes it even rarer. For this reason, the medical understanding of the different presentations of the disease is crucial to ensure an accurate diagnosis and to promote a treatment that guarantees the best prognosis for the clinical condition.

https://doi.org/10.5327/CBN240796

Familial amyloidotic polyneuropathy: an epidemiological study at a university hospital

Camila Oliveira dos Santos[1], Larissa Bittencourt de Carvalho Chaffin[1], Ligia Rocha Andrade[1], Julia Chaves Cordovil[1], Márcia Maria Jardim Rodrigues[1]

[1]Universidade do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Camila Oliveira dos Santos; Email: camilaodsmedicina@gmail.com.

Background: Familial transthyretin amyloidotic polyneuropathy is a severe sensory, motor and autonomic neuropathy that comes from autosomal dominant inheritance. It happens because of the deposition of amyloid material in peripheral nerves and other organs. It can progress because of a severe functional incapacity and, when not treated properly, a person can die in 10 years, approximately. Diagnosis is based on clinical criteria and the confirmation comes by the identification of the mutation in the TTR gene. **Objective:** To identify the epidemiological profile of patients treated by the Amyloidosis team in the neuromuscular diseases clinic. **Methods:** It is a quantitative, observational, and descriptive study that reviewed the medical records of patients seen by the neurology department between August 2023 and July 2024. **Results:** The sample consisted of 46 patients, most of them part of the male gender, with 60.86%. The percentage of deaths in the sample was 4.34%. For the consanguinity parameter, 78.26% had this information in their medical records, of which 30.55% reported consanguinity and 63.88% denied cases in the family. In the family index evaluation, 82.60% of the patients provided the information: the most frequent mentions were the father - with 34.42% - and the patient himself - with 23.68%. 68.88% of patients were symptomatic, of whom 69.56% reported the age of their first symptoms:12.5% had an early onset – that means before the age of 30 - and 46.87% had a late onset - after the age of 50. The average age was approximately 47.97 years, with a standard deviation of around 18.64 years. Among the 34 patients who reported first symptoms, the analysis revealed that paresthesia was the most common symptom, with 18 occurrences. 100% of the patients underwent genetic testing: the Val 50 Met and Val142 Ile variants were the most frequent, with 36.95% and 23.91%, respectively. **Conclusion:** The evaluation of this group of patients revealed that, although familial amyloidotic polyneuropathy is a rare disease, it should be considered in patients that revealed sensory-motor polyneuropathy with dysautonomia, even without a family history. Evaluating the epidemiological profile of this group of patients can provide information on patterns that can guide future research, improve clinical care and reduce underdiagnosed cases.

Familial distal amyotrophy sord related

Nadson Bruno Serra Santos[1], Izadora Vieira Bolzani Lopes Lima[1], Diego Silva Figueredo[1], Aldrin Pedroza Martins[1], Anamarli Nucci[1], Marcondes Cavalcante França Jr.[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Nadson Bruno Serra Santos; Email: nadson_bruno@hotmail.com.

Case presentation: A 63-year-old man was referred to our outpatient clinic and reported frequent stumbling, difficulty in running and jumping, progressing to loss of strength and atrophy in the lower limbs since he was 12 years. At the beginning his symptoms were predominantly distal, with later involvement of the proximal muscles in the lower limbs. He developed bilateral foot drop without complains in sensitivity, and now he is walking with unilateral support. On physical examination he had muscle strength graded IV+ (MRC scale) in iliopsoas, quadriceps and hamstrings. His anterior tibialis and soleus were graded zero and extensor hallucis longus graded I.

Reflexes were all reduced with bilateral abolished Achilles tendon response. His younger brother was 55-years-old by the time of consultation, with past medical history of hypertension and diabetes, and reported a similar clinical picture, with a later onset of symptoms at 17 years. He presented significant loss of strength and muscular atrophy of distal predominance in the lower limbs. On physical examination he had predominant distal weakness with MRC with grade zero strength in the anterior tibialis and triceps surae and abolished reflexes in lower limbs. Both siblings had electroneuromyography with evidence of a chronic diffuse, symmetrical, motor, axonal process, without signs of current denervative activity, of moderate intensity in the upper limbs and severe intensity in the lower limbs. Molecular genetic analysis was performed and confirmed mutation of the SORD gene: c.757del p.(Ala253Glnfs*27) // c.778G> C p.(Gly260Arg). **Discussion:** Despite advances in molecular genetics, Neuropathies "Charcot-Marie-Tooth like" disease of the axonal type (CMT2) and distal hereditary motor neuropathies (dHNM) remain without molecular diagnosis in almost 70% of cases, especially when they are sporadic. In 2020, description of biallelic variants of SORD gene opened a new diagnostic range, highlighting the great potential to solve part of this gap. SORD gene encodes sorbitol dehydrogenase, a key enzyme in the polyol pathway and possibly involved in the development of diabetic neuropathy. CMT2/dHMN first symptoms start 2nd-3rd decade of life and are characterized by cavus feet, a slowly progressive length-dependent motor deficit of lower limbs, often abolished reflexes in lower limbs and preserved in upper limbs. EMG usually reveals distal axonal motor neuropathy, with moderate reduction in motor conduction velocities and/or reduction in the amplitudes of sensory potentials. **Final comments:** Several studies have increasingly shown that biallelic variants of SORD are a frequent cause of autosomal recessive CMT2/dHMN. Screening for biallelic variants of SORD has been recommended in patients with axonal peripheral neuropathy and predominant distal myopathy. Recent studies highlight the potential utility of fasting serum sorbitol and CK levels as sensitive biomarkers of SORD-diseases.

FDG-PET changes in LGI1-encephalitis

Giuseppe Dick Bonato[1], Carolina Heck Haubrich[1], Leticia Bassani Devens[1], Rafael Do Amaral Cristovam[1], Camila Lima Ribeiro[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Carolina Heck Haubrich; Email: carolhhaubrich@gmail.com.

Case presentation: We present the case of a 63-year-old female who was brought to the emergency department due to seizures and progressive memory deficits. She had a prior hospitalization 3 months earlier after presenting with a new-onset generalized tonic-clonic seizure, following a 1-month period of insomnia and forgetfulness. Initially, she was diagnosed with a symptomatic seizure due to severe hyponatremia (116mEq/L), thought to be secondary to multiple oral nootropic drugs. She had no comorbidities, and both brain MRI and prolonged EEG monitoring were normal. She was discharged with normal blood sodium levels and minor improvement in cognitive status, with the recommendation to withdraw oral drugs. During the following 3 months, however, she experienced progressive cognitive deterioration. An FDG-PET was ordered and showed hypermetabolism in the right temporal lobe, and her MoCA score was 18. At the second admission, she had three new short and self-limited episodes of generalized tonic-clonic seizures. Her sodium level was again 116mEq/L. After an extensive search for the cause of hyponatremia, a diagnosis of probable SIADH was made without an evident clinical cause. A new MRI showed no significant findings, and continuous EEG suggested cortical dysfunction with occasional right TIRDAs and FIRDAs. Lumbar puncture results were normal, without pleocytosis and oligoclonal bands. Oral levetiracetam was started, and hyponatremia was slowly corrected; the patient remained seizure-free. Serum anti-LGI1 was ordered, and the patient was discharged with close outpatient follow-up. A month later, results came back positive for anti-LGI1, and the patient underwent corticotherapy with IV 1g methylprednisolone for 5 days followed by oral 80mg prednisone. She showed marked cognitive improvement in the first week after therapy, with MoCA score improving to 26, with minor visuospatial memory deficits. **Discussion:** We presented a case of anti-LGI1 encephalitis with significant improvement following corticotherapy, as consistently shown in previously reported cases. Clinical criteria for limbic encephalitis were all met except for the absence of MRI changes. Most cases present with typical bi-temporal changes on MRI; however, they can show multiple patterns of impairment. Metabolic imaging could reveal more subtle temporal changes and act as a more precise tool for diagnosing limbic encephalitis. There is, however, a lack of definite criteria for analyzing FDG-PET imaging, as anti-LGI1 encephalitis can present as either hypo or hypermetabolism in the temporal lobes or basal ganglia. The presence of anti-LGI1 antibodies in such cases is indispensable. **Final comments:** Anti-LGI1 encephalitis is considered the second most common autoimmune encephalitis and tends to show good outcomes. It may be beneficial to have a low threshold for considering it even when not all criteria for limbic encephalitis are met, especially if paraclinical signs such as hyponatremia are present.

Feasibility analysis of using non-invasive monitoring technology to assess brain compliance during sleep

Karla Carlos[1], Carla de Oliveira Carletti[1], Lívia Jane Galvão Farias[1], Tainã Paulo Zanata Trombetta[1], Douglas Sousa Soares[1], Ana Flavia Machado Pitz[1], Letícia Lambert[1], Lucas Martins Teixeira[1], Gilmar Fernandes do Prado[1]

[1]Universidade Federal de São Paulo, Escola Paulista de Medicina, São Paulo SP, Brazil.

Correspondence: Karla Carlos; Email: ka.carlos1@hotmail.com.

Background: Accurately monitoring intracranial pressure waveforms in a noninvasive, cost-effective, and safer manner could assist in managing patients with imbalances in cerebral homeostasis and autoregulation challenged by some sleep disorders. The Brain4care (B4C) technology can detect small cranial deformations caused by changes in intracranial pressure linked to the cardiac cycle. **Objective:** To analyze the feasibility of using the B4C device with a Type I sleep study (PSG) all night. **Methods:** After completing the PSG setup, we placed the B4C headband around the patient's head, letting the sensor just above the ear at the frontotemporal transition. We verified the register time, signal continuity, sensor displacement, device tolerability, and quality of derived variables like wave morphology relation P2/P1, and entropy. A reliable signal should be 5 minutes long and free of any artifacts for analysis. **Results:** We included 51 participants (30 females), with a mean age of 39±12 years. The sensor was positioned on the left side in all patients due to the location of the right oculogram electrode of the PSG. The B4C recording's duration mean was 315±153 min (5 hs and 15 min) of continuous monitoring (maximum: 468; minimum:162). The average morphology of the acquired pulse was analyzed minute by minute, and the analysis did not include minutes with insufficient sample sizes. The average entropy was 2.0 ± 0.44 (maximum value of 2.2; minimum value of 0.5), representing the degree of data dispersion. Discussion. This is the first study showing that a B4C headband can be tolerated by most patients during a Type I sleep study, which requires a lot of wiring, without causing additional discomfort to the patient. The proper and precise placement of the device allows it to remain in stable contact with the patient's scalp, ensuring good acquisition of pulse morphology determined by small cranial deformations associated with ICP. Most studies documenting the use of this device involve an average usage time of 7.5 minutes for data recording. There is no data about the behavior of cerebral compliance during a night sleep monitored by PSG. Once the brain needs to precisely control the cerebral flow, and sleep is a neurophysiological and physiological variable state that includes the brain, it is of interest to monitor how brain compliance (indirectly associated with ICP) behaviors in normal and abnormal sleep. **Conclusion:** Noninvasive intracranial compliance monitoring technology through the Brain4care® device during sleep is safe and feasible. Our maximum recording time was 25 times longer than in other neurological research protocols. No patients experienced decoupling or loss of the Brain4care® device during the night of sleep. Patients reported that using the device did not cause any painful discomfort. The sensor should be positioned on the left side when used in conjunction with PSG.

Femoral neuropathy secondary to compression by retroperitoneal hematoma: a rare differential diagnosis for neuroschistosomiasis

Mariana Holanda Gameleira[1], Maria Iris de Morais Machado[1], Rosevaldo Alves Junior[1], Lucas Chaves Lima[1], Brenda Letícia Lopes Batista[1], Yanne Almeida Aguiar[1], Brenda Albuquerque de Araújo Marinho[1], Bárbara Borges de Oliveira[1]

[1]Hospital da Restauração, Recife PE, Brazil.

Correspondence: Mariana Holanda Gameleira; Email: marianagameleira_@hotmail.com.

Case presentation: A 53-year-old female patient came to hospital with sudden onset of low back pain radiating to the lower limbs, worse on the left, accompanied by ipsilateral motor and sensory deficits. She has advanced chronic liver disease due to schistosomiasis, and was in the ICU about two weeks before the neurological episode due to acute pulmonary edema. She developed severe low back pain and motor and sensory deficits in the left lower limb, and hematocrit drop requiring blood transfusion. No sphincter disorders. The examination showed weakness in hip flexion and knee extension, patellar hyporeflexia on the left and hypoesthesia and pain in the anterior aspect of the thigh and medial aspect of the leg. As the patient had schistosomiasis, cerebrospinal fluid analysis, which was normal, and imaging tests were performed for differential diagnosis. Magnetic resonance imaging spine did not show compressive disturbance compatible with the clinical case. However, a large infrarenal retroperitoneal hematoma was observed, compressing the left psoas muscle. Abdominal arteriography was performed to define the bleeding origin, showing splenorenal shunt and mass effect of the hematoma on the left kidney and psoas muscle. Electroneuromyography of the lower limbs was also performed, showing acute left lumbar axonal plexopathy (femoral nerve mostly affected) related to compression by retroperitoneal hematoma. Discussed case with surgery team, conservative treatment was chosen because of the risk of hemodynamic instability. **Discussion:** In patients with liver disease, there is an increased risk of complications such as digestive bleeding and coagulopathies, which can cause hematomas in the retroperitoneal region. Hemorrhage in iliopsoas muscle is a rarely described etiology of neuropathy. Its presentation is usually unilateral, with symptoms related to compression of the nervous plexus of the lower limb and with a wide differential diagnosis, one of which is neuroschistosomiasis. Symptoms depend on the presence of the parasite in the brain, cerebellum, subarachnoid space or spinal cord; the last one is most commonly affected. For

understanding the symptoms, anatomical knowledge is essential. The femoral nerve begins at the union of L2-L4 roots, which run through the iliopsoas muscle tendon and the femoral canal, providing motor and sensory innervation to the lower limb. Due to the compressive action of the hematoma, the clinical is wide, initially with sudden low back pain, up to paresthesia or paresis, and massive bleeding and shock may occur. The diagnosis is based on clinical and imaging examination showing increase volume on affected muscles, in addition to compatible electroneuromyography. Treatment involves hematoma drainage and control the underlying etiology. **Final comments:** Ileopsoas retroperitoneal hematoma should be considered in cases of compressive axonal injury in the lower limbs as a cause of significant femoral neuropathy.

Finding the spot: results of a noninvasive strategy in MRI negative patients submitted to epilepsy surgery guided by ECoG

William Alves Martins[1], Fernanda Schuh Martins[1], André Luis Fernandes Palmini[1], Eliseu Paglioli[1], Thomas Frigeri[1], Rafael Paglioli[1], Ricardo Paganin[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Fernanda Schuh Martins; Email: fschuhmartins@gmail.com.

Background: Epilepsy surgery is crucial for treating patients with pharmacoresistant epilepsy. Seizure freedom is closely linked to the complete resection of the lesion, but patients with normal or negative MRI results have poorer outcomes. For these patients, extensive presurgical investigations often fail to provide sufficient data for a surgical plan, leading to the use of chronic extra-operative monitoring with subdural grids or SEEG. However, this approach is often too costly for many epilepsy patients, especially in developing countries. **Objective:** To describe the surgical outcomes of MRI-negative patients who underwent non-invasive investigations followed by ECoG-guided cortical resection. **Methods:** From 2012 to 2019, 62 MRI-negative patients underwent epilepsy surgery at the Porto Alegre Epilepsy Program (PAESP) and had at least 12 months of follow-up. The cohort included 36 males (58.1%) and 4 patients (6.5%) with a history of febrile seizures, with a mean age at surgery of 29±15 years. The median follow-up period was 43 months (12-146 months), showing a significant reduction in seizure frequency (58.5 to 7.2; p=0.001). Resections were temporal in 34 patients (54.8%), frontal in 17 (27.4%), multi-lobar in 4 (6.5%), occipital in 5 (8.1%), and parietal in 2 (3.2%). At 12 months, 29 patients (47%) were seizure-free, with 20 (32.3%) remaining completely seizure-free (Engel Ia) at last follow-up. Engel class distribution was I: 25 (40.3%), II: 13 (21%), III: 14 (22.6%), and IV: 10 (16.1%). There was a small trend toward better seizure freedom for temporal resections at last follow-up (41.2% vs. 21.4%, p=0.112). **Results:** Our long-term results, showing 32% seizure freedom in MRI-negative patients, align with literature that typically involves intracranial EEG. A meta-analysis indicated seizure-freedom rates of 34-45% for nonlesional MRI patients, compared to higher rates for lesional patients. Late recurrence occurred after a year in a third of those initially seizure-free, yet Engel I was seen in 40.3% of patients in a median follow of 43 months. This pattern of recurrence could be due to more widespread underlying conditions like FCD type I, the most common pathological finding in nonlesional epilepsies, leading to reactivation of epileptic foci following tapering of antiseizure drugs. Consistent with our findings, Wang et al. also identified FCD I as the predominant pathological substrate in 40% of MRI-negative patients. **Conclusion:** Combining strong electroclinical hypotheses and noninvasive tests with ECoG-guided resection can be an effective strategy. Novel noninvasive evaluation methods are needed to expand access to epilepsy surgery in low-resource countries.

Correspondence: Paulo Victor Sgobbi de Souza; Email: pvsgobbi@gmail.com.

Background: ALSP is a rare, autosomal-dominant, neurodegenerative disorder caused by a colony-stimulating factor1 gene (CSF1R) mutation and characterized by brain white matter (WM) demyelination, swollen axons, and pigmented glial cells and clinical symptoms of cognitive, neuropsychiatric, and motor dysfunction, typically developing around 40 years of age. No approved therapies exist. **Objective:** Report clinical, biomarker, and MRI findings from ILLUMINATE, the first NHS in individuals with ALSP (NCT05020743). **Methods:** ILLUMINATE is a prospective, multicenter NHS of individuals with definitive or prodromal (satisfies genetic and radiologic but not full clinical symptom criteria) ALSP. Up to 50 enrollees will be followed for 24 months, with clinical assessments and MRI collected at screening and every 6 months. MRI ALSP severity score and WM lesion and regional brain volumes will be derived; blood and cerebrospinal fluid (CSF) disease biomarkers will be measured at specific visits. **Results:** As of September 2023, of 41 enrollees with a confirmed CSF1R mutation, 23 were symptomatic (mean±SD age, 45.2±9.5 years; 52.2% female) and 18 were prodromal (42.9±17.0 years; 47.8% female). Baseline WM lesion and ventricle volumes were higher in symptomatic vs prodromal participants, while total gray matter volume was lower. Longitudinally, greater expansion in WM lesion volume and ventricle volume and gray matter volume reduction were observed in symptomatic vs prodromal participants. Baseline soluble CSF1R was substantially reduced in prodromal and symptomatic participants vs healthy volunteers, indicating reduced microglial activity. CSF and serum levels of neurofilament light chain (NfL), a marker of neuroaxonal injury, were elevated multifold in symptomatic participants vs prodromal and healthy individuals. Longitudinal fluid biomarker and clinical data will be disclosed at the meeting. **Conclusion:** These ILLUMINATE findings demonstrate that MRI measures and NfL levels are sensitive markers of ALSP pathophysiology, with potential to inform optimal clinical endpoints and therapeutic intervention study design in ALSP and improve overall understanding of disease progression.

Correspondence: Brendha David Pinto; Email: brends3003@gmail.com.

Background: Wilson's disease (WD) is an autosomal recessive disorder resulting in a defect in copper metabolism. This defect leads to decreased excretion of this metal and its accumulation in organs such as the liver, brain, and eyes. Clinical manifestations are often nonspecific and variable, including extrapyramidal symptoms and the presence of Kayser-Fleischer rings, indicating extrahepatic copper accumulation. Diagnosis commonly relies on the triad: serum levels of ceruloplasmin and copper, urinary copper excretion and, when necessary, liver biopsy. However, the early detection of chronic neurodegeneration remains challenging, as neurological symptoms usually appear after hepatic symptoms, thereby complicating both monitoring and comprehension of disease progression. Therefore, it is crucial to have methods that allow the tracking of neuronal degeneration for maintaining the health of affected individuals. The literature suggests the use of Optical Coherence Tomography (OCT), a non-invasive imaging exam already employed in the monitoring of patients with multiple sclerosis. This method is based on measuring the thickness of axons that compose the retinal nerve fiber layer, assessing its neuronal integrity. However, due to the limited number of patients with the disease undergoing the exam, it is still not possible to use OCT as a marker of neurodegeneration for WD. **Objective:** To investigate whether there is a significant difference in the retinal changes detected by OCT between patients with neurological manifestations of WD and those with exclusively hepatic symptoms. **Methods:** Ten patients with neurological manifestations and ten with exclusively hepatic manifestations of the disease were selected, and their clinical and epidemiological information was recorded. Subsequently, they will undergo neurological examination guided by the Global Assessment Scale for Wilson's disease (GAS-WD), ophthalmological evaluation, and OCT examination to measure the retina's thickness in six ocular sectors. After data collection, normality analysis will be performed using the Shapiro-Wilk test. For normally distributed data, the t-student test will be used, and for non-normally distributed data, the Mann-Whitney test will be employed. **Results:** The study is currently ongoing, with patient data being collected and analyzed. **Conclusion:** The research results are expected to show a high incidence of retinal changes in patients with neurological symptoms of WD. Such findings could support the use of OCT as a method for monitoring neurodegeneration progression in these individuals.

Fine motor dexterity impairment in a large group of people with epilepsy without lesions in the motor areas

Gabriela Ribeiro Prada[1], Marina Alvim[1], Rafael Batista João[1], Lucas Scárdua Silva[1], Thais Maria Bezerra[1], Fernando Cendes[1], Mateus Henrique Nogueira[1], Clarissa Lin Yasuda[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Gabriela Ribeiro Prada; Email: g236806@dac.unicamp.br.

Background: While several neuroimaging studies have demonstrated gray matter atrophy in the precentral gyri, basal ganglia and alterations of corticospinal tracts in focal and generalized epilepsies, little is known about the fine motor alterations in people with epilepsy (PWE). Besides, fewer studies have investigated the impact of symptoms of anxiety and depression on motor performance. **Objective:** To investigate gross and fine motor dexterity in PWE and possible associated factors such as

depression and anxiety. **Methods:** We interviewed and tested 195 people with epilepsy (PWE, median of 35 years of age and 11 years of education) at a Tertiary Centre (before their outpatient appointment) and 252 healthy volunteers (HV, median of 35 years of age and 15 years of education) at the University Campus. All individuals performed the 9-hole peg test (9-HOLE), Box and Block Test (BBT), Tower of Hanoi (TH), the Block design subtest of the Wechsler Adults Intelligence Scale (BD-WAIS), Generalized Anxiety Disorder Questionnaire (GAD-7) and Neurological Disorders Depression Inventory for Epilepsy (NDDI-E). PWE was separated into seizure-free (76 subjects), lower-frequency (13 subjects) and pharmacoresistant (85 subjects). We used SPSS23 for statistical analyses with non-parametric tests for group comparisons (Mann-Whitney and Spearman correlation). We excluded subjects with intellectual or motor impairment. **Results:** Although the groups of PWE and HV were balanced for age (p=0.7), scores of anxiety (GAD-7, p=0.4) and of depression (NDDI, p=0.2), we detected poor performance of 9-HOLE (bimanual, p<0.001), BBT (bimanual, p<0.001), TH (bimanual, p<0.001), and of BD-WAIS (bimanual, p<0.001). Overall, the PWE performance was 15-22% worse than their age-paired controls; patients were twice slower than controls to finish the first movement of the Tower of Hanoi. We did not observe significant differences in motor performance related to seizure control. **Conclusion:** Although groups of patients and controls presented similar levels of anxiety and depression, our results consistently showed poor motor performance for PWE, related to both fine dexterity (9-hole peg test) and gross tests (Box and Block Test). Besides, PWE also presented worse scores for more complex tests (Block design subtest of the Wechsler Adults Intelligence Scale and the Tower of Hanoi) that require integration of different cognitive functions. These findings add new information related to epilepsy comorbidities, as little is known about fine motor impairment in patients with generalized and focal epilepsies (without lesions in the motor cortex, corticospinal tracts or basal ganglia). Future analyses with subgroups of different types of epilepsies and the effects of different types of medications are necessary to understand the dysfunction and create specific strategies for rehabilitation.

Background: Risdiplam (EVRYSDI®) is a centrally and peripherally distributed, oral survival of motor neuron 2 (SMN2) pre-mRNA splicing modifier, approved in over 100 countries worldwide. **Methods:** FIREFISH (NCT02913482) is a multicenter, open-label, two-part study of risdiplam in children with Type 1 spinal muscular atrophy (SMA) and two SMN2 gene copies (inclusion criteria: 1-7 months old at enrollment). In the dose-finding Part 1 of FIREFISH the safety, tolerability, and pharmacokinetics/pharmacodynamics of different risdiplam doses were assessed. The pivotal Part 2 assessed the safety and efficacy of risdiplam over 24 months at the dose selected from Part 1. Thereafter, children entered a 3-year open-label extension phase and continued to receive risdiplam at the pivotal dose. **Results:** The FIREFISH results after 4 years of risdiplam treatment showed that 91% of children were alive and 81% did not require permanent ventilation. Additionally, children either maintained or improved their motor skills in terms of developmental milestones and motor function, which is not observed in the natural history of Type 1 SMA. Pooled safety and efficacy data were available from 58 enrolled infants who completed risdiplam treatment over a period of 5 years (Part 1 high-dose cohort, n=17; Part 2, N=41). The last FIREFISH patient completed their final assessment after 5 years of risdiplam treatment at the pivotal dose on December 22, 2023. Here we present the final pooled safety and efficacy results from the FIREFISH study after 5 years of risdiplam treatment. **Conclusion:** FIREFISH Parts 1 and 2 provide long-term clinical trial safety and efficacy data on risdiplam in the treatment of Type 1 SMA. Acknowledgments: The authors would like to thank all the patients who participated in this study, their families, as well as the investigators and trial staff. This study was sponsored by F. Hoffmann-La Roche Ltd, Basel, Switzerland.

First Brazilian study in central disorders of hypersomnolence using precision medicine: high-resolution hla sequencing and hypocretin levels in patients with narcolepsy and idiopathic hypersomnia

Christianne Martins Correa da Silva Bahia[1,2], Luis Cristovao Porto[1], Victoria Mendes Oliveira[1], Danielle Angst Secco[1], Romulo Vianna[1], Gilson Costa dos Santos Junior[1], Carlos Otavio Brandão[3], Emmanuel Mignot[4], Bruna de Freitas Dias[4], Soniza Vieira Alves Leon[2,5,6]

[6]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Christianne Martins Corrêa da Silva Bahia; Email: christiannemartins@gmail.com.

Background: Narcolepsy and idiopathic hypersomnia (IH) are prominent central disorders of hypersomnolence. HLA-DQB1*06:02 is the primary genetic risk factor for narcolepsy, but other alleles have also been identified. However, data on these conditions in Brazil is limited, as previous studies have focused solely on this allele without exploring hypocretin measurement, now considered a biomarker for NT1. Ongoing research aims to find a biomarker for diagnosing narcolepsy type 2 (NT2) and IH. Therefore, genetic studies in diverse populations like Brazil are essential to provide valuable information on primary hypersomnias. **Objective:** To investigate the genetic characteristics associated with susceptibility or protection for narcolepsy and IH in the Brazilian population using precision medicine for diagnosing NT1 and NT2. **Methods:** Diagnosis of narcolepsy and IH was based on the third version of the International Classification of Sleep Disorders, with sub-classification into NT1 and NT2 determined by CSF hypocretin 1 concentration using radioimmunoassay. High- resolution HLA sequencing for class I (A, B, and C) and class II (DPB1, DRB1, and DQB1) alleles was conducted using massive parallel sequencing. The study compared data obtained with the National Registry of Bone Marrow Donors (REDOME) database, matching by sex, self-declared ethnicity, and geographic location in a ratio of 1 case to 5 controls. **Results:** The study included 45 narcolepsy patients and 225 controls, as well as 11 IH patients and 55 controls. Genetic differences, indicated by the Fixation Index, were observed between NT1 patients (n=17) and controls (n=85), as well as between NT1 and NT2 (n=16) groups, with significant p-values (p<0.001). NT1 patients exhibited a higher frequency of the HLA-DQB1*06:02 allele compared to controls and NT2 patients (88.24% vs. 23.53% vs. 18.75%, respectively; p<0.001). Following DQB1*06:02, DRB1*15:03 was identified as the most common allele associated with NT1, forming a haplotype with an odds ratio of 9.5 compared to controls (95% CI: 2.93-30.81, p<0.005). Rare haplotypes were also found in three NT1 cases. IH did not show significant genetic risk alleles compared to controls or narcolepsy groups after Bonferroni correction. There were no differences in hypocretin values between NT2 and IH groups. **Conclusion:** This first Brazilian study on primary hypersomnias using precision medicine revealed that HLA-DQB1*06:02 is the main genetic risk factor for NT1 but not for NT2 and IH. Notably, DRB1*15:03, rather than DRB1*15:01, was more prevalent among NT1 Brazilian patients, and this allele has been described in several studies as associated with African heritage. Rare haplotypes were found in some cases, suggesting they may be more frequent among Brazilians. In contrast to NT1, NT2 and IH patients did not exhibit significant genetic differences in HLA sequencing compared to their controls.

Five-year experience in spinal muscular atrophy treatment with nusinersen: a single-center experience

Rodrigo Holanda Mendonça[1], Graziela Jorge Polido[1], Ciro Matsui Jr[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, São Paulo SP, Brazil.

Correspondence: Graziela Jorge Polido; Email: grazielapolido@gmail.com.

Background: Spinal muscular atrophy (SMA) is a genetic motor neuron disease caused by mutations in the SMN1 (Survival Motor Neuron) gene, which leads to childhood-onset muscle weakness. Nusinersen, the first approved treatment for SMA, is an antisense oligonucleotide for intrathecal use, which leads to greater survival and gain in motor acquisitions. Studies on the safety and efficacy of long-term treatment are still scarce. **Objective:** To present long-term results (5 years of follow-up) in SMA patients under treatment with Nusinersen. **Methods:** We followed a total of 24 patients with SMA type 1 and 30 patients with SMA type 2 and 3. The patients were evaluated by the functional scales CHOP-INTEND (The Children's Hospital of Philadelphia Infant Test of Neuromuscular Disorders) and Hammersmith Functional Motor Scale Expanded (HFMSE), in relation to gain of motor milestones (head control, sitting with or without support, standing and walking) in addition to assessment of survival and use of continuous ventilation (CV) and feeding route. **Results:** Among SMA type 1 patients, after five years of follow-up, 22 (91.6%) patients are alive, two deaths occurred: one after gene therapy and the other after respiratory failure. Two patients received gene therapy but continued to use Nusinersen - combined therapy. Eight patients gained some motor milestone, all of them started treatment before 12 months disease. The greatest gains in CHOP-INTEND occurred up to 24 months of treatment, and after this period, the scores tended to stabilize, without further gains. Thirty patients with SMA types 2 and 3 were followed for five years. In these patients, five developed severe scoliosis, defined by a Cobb angle greater than 45°, and six underwent spinal arthrodesis, totaling eleven patients (36.6%) with clinically significant spinal deformity. These patients began to demand greater

complexity in the intrathecal application, requiring the use of imaging (Fluoroscopy or computed tomography) in subsequent applications. From a motor point of view, the HFMSE assessment showed an average gain of +2.1 (±6.9) and +1.3 (±7.1) points at 36 and 48 months of follow-up, respectively. In 48 months of treatment, 21 patients (70%) remained stable or continued to gain points in long-term follow-up, and nine patients (30%) lost 2 or more points on the scale, these developed severe scoliosis or underwent arthrodesis of column. **Conclusion:** Nusinersen showed continuous benefit over five years of treatment, bringing motor improvement mainly within the first 2 years of treatment and maintaining motor function acquired at 4 years. Among SMA type 1, only patients who started treatment before 12 months of illness gained some motor milestone. No new adverse events were reported in this long-term follow-up.

Fluctuating scoliosis due paravertebral dopa-responsive dystonia

Caio César Alves Lins de Oliveira[1] , Lara Candido Pena[1], Alex de Novais Batista[1], Lisa Ananda Rodrigues Soares[1], Laura Luiza Barbosa Menezes da Mota[1], Leonardo Monteiro Lauria[1], Virgílio Sátyro da Nóbrega Segundo[1], Carlos Frederico Leite de Souza Lima[1]

[1]Hospital Universitário Oswaldo Cruz, Recife PE, Brazil.

Correspondence: Caio César Alves Lins de Oliveira; Email: caiolins97@gmail.com.

Case presentation: A 22-year-old male patient presented in the moviment disorders outpatients clinic of the Neurology service in March 2021 complaining of paravertebral muscles involuntary and sustained contractions throughout the day for approximately 7 months. He stated that this symptomatology resulted in the formation of scoliosis with a fluctuating pattern, being described as worse in the morning and lessening at the end of the day. On physical examination, was observed paravertebral muscles involuntary and sustained contraction, culminating in thoracolumbar scoliosis, other examination parameters was normal. Therefore, considering the age range and fluctuating nature of postural changes due paravertebral dystonia, Levodopa 100mg in association with benserazide 25mg (Prolopa BD) was prescribed 3 times a day, as a therapeutic test based on the main diagnostic hypotheses of the case. The patient returned to the consultation approximately 3months after starting the medication, reporting and showing substantial improvement of contractures in the dorsal region, in addition to a significant reduction in the degree of scoliosis with resolution of its fluctuating nature. He denied adverse effects from the use of medication. **Discussion:** Dopa-responsive dystonia (DRD) encompasses a clinically and genetically heterogeneous group of disorders that generally manifest as dystonia of appendicular onset, but which can also begin in the axial muscles, which fluctuates throughout the day and improves with the use of low-dose levodopa. Its origin is related to disorders in the dopamine synthesis pathway, mainly due to dysfunction or deficiency of the enzymes responsible for its biosynthesis, such as Guanosine Triphosphate Cyclo-Hydrolase 1 (GTP-CH-1), Tyrosine Hydroxylase (TH), Sepiapterin Reductase and Pyruvate Tetrahydrobiopterin Synthase. The diagnosis of DRD is generally based on the presentation of symptoms and therapeutic tests with levodopa, however the definitive diagnosis, with specific etiological determination, is made through genetic tests such as whole exome sequencing. Although the patient had a typical history and met the DRD diagnostic criteria, he was not subjected to genetic testing due to unavailability in the Brazilian Unified Health System (SUS). **Final comments:** DRD is a condition that, despite being rare, should be always be considered, given the age group affected, the degree of negative impact on patients' quality of life when left untreated and also due to the great symptomatological response to the use of Levodopa, which is a medication easily accessible through public government programs. Furthermore, a greater accessibility to genetic tests that enable definitive diagnosis is extremely important for genetic counseling of patients and their families, and also for a better understanding of the different clinical-epidemiological manifestations of DRD.

Focal impaired awareness seizures in patient with choroidal fissure cyst

Wesley Alfredo Gawlinski de Arruda[1], Thaise Fellini Dal Moro[1], Estevão Daniel Wohlenberg[2]

[1]Hospital São Vicente de Paulo, Passo Fundo RS, Brazil.
[2]Universidade Federal da Fronteira Sul, Passo Fundo RS, Brazil.

Correspondence: Wesley Alfredo Gawlinski de Arruda; Email: wesley.alfredo@hotmail.com.

Case presentation: A 71-year-old female patient with no previous history of neurological events began experiencing mental confusion and cognitive decline a few months ago, with episodes of "blackouts" starting to occur approximately 8 days ago. According to family members, she would become apathetic, unresponsive, and unable to communicate, not improving when called during a regular conversation or while performing daily activities, lasting for a few seconds but sometimes up to a minute. Neurological examination showed no abnormalities. Cognitive screening revealed significant impairment (Semantic Verbal Fluency Test (SVFT) with 5 animals in 1 minute, Sunderland Clock Test (SCT) 2/10, Mini-Mental State Examination (MMSE) score of 21 points), but no functional loss according to family members (Pfeffer = 0 points). Brain Magnetic Resonance Imaging (MRI) identified a right-sided choroidal fissure cyst in the temporal lobe measuring 1.3 x 0.9 cm. Electroencephalogram (EEG) with normal baseline rhythm showed interictal spike discharges in the right temporal region, with an electrographic seizure (with clinical manifestation) beginning in the ipsilateral temporal region, lasting approximately 2 minutes. Therefore, due to the hypothesis of epilepsy with focal impaired awareness seizures secondary to choroidal fissure cyst, treatment with an antiepileptic drug (Levetiracetam 250 mg BID) was initiated. About two months later, the patient returned for reassessment, showing substantial cognitive improvement (SVFT = 13 animals in 1 minute, SCT 9/10, MMSE 24 points), with the patient and family denying any new episodes of "blackouts" or seizures, and being well-adapted to the medication. **Discussion:** The choroidal (or choroid) fissure is a cleft in the lateral ventricle between the fornix and thalamus, which can develop cysts due to errors during embryonic choroid plexus formation. Although small cysts are common and often asymptomatic, some studies suggest a connection between these cysts and epilepsy, but their causal relationship is still controversial. Neuroimaging (especially magnetic resonance imaging) is extremely useful for differentiating choroidal fissure cysts from other differential diagnoses, including cystic neoplasms, dermoid/epidermoid cysts, and choroid fissure enlargement due to focal temporal lobe atrophy. If a patient presents with clinical symptoms suggestive of epilepsy, with electroencephalogram (EEG) findings compatible with a focal disorder, seizures can be controlled with the use of antiepileptic drugs. **Final comments:** Choroidal fissure cyst is a brain lesion known to be predominantly asymptomatic. However, as in the case of our patient, secondary epilepsy due to a temporal lobe lesion may occur. The correlation between focal epilepsy and cysts in the choroidal fissure is present, but a causal relationship is not yet well established, highlighting the need for further studies on the topic.

Foot drop as the predominant symptom in facial onset sensory and motor neuronopathy (FOSMN)

Izadora Vieira Bolzani Lopes Lima[1], Aldrin Pedroza Martins[1], Nadson Bruno Serra Santos[1], Diego Silva Figueiredo[1], Fabricio Diniz de Lima[1], Alberto Rolim Muro Martinez[1], Anamarli Nucci[1], Marcondes Cavalcante França Junior[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Izadora Vieira Bolzani Lopes Lima; Email: izadoralima7@gmail.com.

Case presentation: A 59-year-old woman with no past medical history, presented in 2019 signs of right-side tongue paresthesia. Later in the same year, she developed difficulties using high heels because her shoes slipped off her feet. By 2021, she started using a unilateral stick on the right side due to frequent falls. In 2022 the patient noted dysarthria and dysphagia, searching for medical assistance. Later in 2023, she was referred to our hospital for further investigations. At the first consultation her neurological examination revealed bilateral loss of touch and pinprick sensation affecting all trigeminal branches and bilateral facial paresis with a prominent wrinkle between the mouth and the chin, bilaterally. There was also mild dysarthria and tongue atrophy specially on the left side with fasciculations and marked atrophy of both sternocleidomastoids, with difficult to hold the head in the supine position. There was weakness graded IV(according MRC) in her deltoids, triceps, iliopsoas, quadriceps femoris and hamstrings muscles. Both tibialis anterior and triceps sural were grade III. She could not walk on tip toes or on the heels. The sensory examination revealed numbness of the upper limbs. Deep tendon reflexes were all absent. There was no auditory disfunction. Brain magnetic resonance imaging (MRI) revealed mild nonspecific gliosis. The CSF was normal. Neurophysiology examination exposed a preganglionic, chronic and asymmetrical motor neuronopathy of bulbar, cervical, thoracic and lumbar segments, with signs of acute denervation. There was also multifocal, not length-dependent neuropathic sensory involvement of moderate intensity, compatible with a sensory neuronopathy. These concomitant patterns in association with prolonged R2 latency on blink reflex were highly suggestive of FOSMN. The patient was then started on Riluzole 50mg twice a day therapy with relative slowdown of progression of her disease. **Discussion:** FOSMN is a rare disease caracterized by asymmetrical facial and perioral numbness and paresthesia with reduced touch and pain sensation in the trigeminal distribution and progression of sensory symptoms to the upper trunk. Lower motor neuron signs are noted by muscle weakness and wasting, especially in the face, neck and upper limbs. Most references consider FOSMN a TDP-43 proteinopathy within the amyotrophic lateral sclerosis-FTD spectrum. Diagnosis is established based on clinical signs and symptoms with exclusion of similar conditions and the absence of the blink reflex on EMG in addition to denervation. **Final comments:** Clinicians must be aware of of the doble neuronopathy of FOSMN and, that the interval between the onset of facial sensory signs and weakness can range from years to simultaneous onset and patients tend to neglect pure sensory symptoms, delaying diagnosis. Treatment is still controversial as some sources report little or no benefit from immunotherapies or riluzole and more research is needed for this purpose.

Foramen ovale electrodes can identify a focal seizure onset when surface EEG fails in mesial temporal lobe epilepsy?

Izabela Dayany França Feitosa[1], Marina Teixeira Ramalho Pereira Dalio[1], Frederico Nakane Nakano[1], Alexandre Veriano Junior[1], Americo Ceiki Sakamoto[1], Tonicarlo Rodrigues Velasco[1]

Correspondence: Izabela Dayany França Feitosa; Email: draizabelafeitosa@gmail.com.

Temporal lobe epilepsy (TLE) is the most common form of focal epilepsy in adults, with mesial temporal lobe epilepsy associated with hippocampal sclerosis (MTLE-HS) is the commonest subtype. Approximately 30% of MTLE patients are pharmacoresistant (CHOI, 2008), half of them are candidates for temporal lobe resection (ROSENOW, 2001). For indication of surgery, is necessary the accurate delineation of the epileptogenic zone, which can be defined from the analysis of the seizure, interictal and ictal electroencephalogram activity, analysis of highresolution MRI (KILPATRICK, 1997). However, the surface EEG fail to demonstrate an unambiguous unilateral ictal onset, semi-invasive studies, with foramen ovale electrodes (FOE), and/or invasive studies with depth electrodes (stereotactic depth electrode implantation or subdural grids/strips) is necessary (DIEHL, 2000). In the present study, we analyze the data of 161 patients with MTLE undergoing evaluation with foramen ovale electrodes. The evaluation with FOE was performed when the surface EEG presented: (a) bitemporal independent seizures, (b) non lateralized ictal onsets, (c) side contralateral to the side of hippocampal sclerosis. When the FOE study was also unable to define an unequivocal ictal onset, an evaluation with invasive electrodes was proposed. EFO was effective in 91 cases (56.5%). Of these 78 patients undergo a temporal lobectomy surgery with 73.1% of patients who are free of crises. Twenty-one patients were evaluated with invasive electrodes after FOE study. The invasive electrode confirmed the results of FOE in 16 (76.2%) cases. The study with invasive electrodes guided a surgical procedure in 7 patients and temporal lobectomy was performed, making 04 patients (57.1%) free of seizures. The evaluation with foramen ovale electrodes is cost-effective, well tolerated by patients and has a lower rate of complications when compared to other methods. Therefore, we conclude that EFO evaluation, after nonconcordant surface EEG, can be a safe alternative, more economical when compared to the implantation of invasive electrodes and with an excellent postoperative outcome in a patient with MTLE.

Foreign accent syndrome in a patient with stroke at pons: case report

Danielli Regina da Silva[1], Airton Sena Oliveira Sales[1], Laisy Bárbara Souza Silva[1], Amanda Soares Pimenta[1], Daniela Aparecida Lima Viana[1], João Henrique da Matta Clementino[1], Ana Luisa Rufino de Sousa[1], Elisangela Ferraz Pazinato[1], Giovani Zago Borges[1], Danielle Patrícia Borges Margato[1]

[1]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Amanda Soares Pimenta; Email: amandaspiment@gmail.com.

Case presentation: Female, 51 years old, Brazilian, previously type 1 diabetic, insulin-requiring, in addition to dyslipidemia, heart disease and hypothyroidism, admitted to a teaching hospital in a city located in the Triângulo Mineiro region, in 2015, with a history of speech and language alterations for a week, associated with hypoglycemia on admission. Dysarthria and/or aphasia were not identified, with writing and language comprehension preserved, however the patient had divergent fluency in relation to the native language. At the time, the patient denied changes in behavior, strength, sensitivity, balance, sleep and wakefulness, headache and/or other neurological signs and symptoms. An investigation was carried out for a possible cerebrovascular event during hospitalization, and a lesion with an ischemic appearance on the leftside of the pons was then identified in an imaging study, identified on a T2-weighted sequence. Reevaluated in May 2024, with the speech alteration maintained. **Discussion:** Foreign accent syndrome (FAS), considered a rare speech disorder, is characterized by the emergence of an accent perceived as "foreign" due to the combination of segmental deficits, such as phonetic distortions and phonemic paraphasias, associated with suprasegmental changes with accentuation, variation of tone and rhythm. Stroke is the most common etiology, generally with left frontal brain lesions, which differs from the reported case. However, other etiologies are found, such as trauma, metastatic breast carcinoma, multiple sclerosis and migraines. The pathological lesions have a wide and heterogeneous anatomical location, which include the left basal ganglia, left corona radiata and internal capsule, right precentral and postcentral gyri, right middle cerebral artery region, right frontal area, brainstem and cerebellum. Thus, it is believed that in FAS there is interruption of widely distributed speech networks and there is not just one anatomical location affected. However, it is still a poorly understood and studied syndrome, given its rarity and complexity. **Final comments:** This report reinforces the complexity of FAS, highlighting the interruption of speech networks widely distributed in the brain, which makes it difficult to identify a precise anatomical location as the sole cause. Current understanding is limited due to its rarity and etiological diversity, requiring further studies to elucidate its underlying mechanisms and optimize therapeutic approaches. In short, this patient's case highlights the importance of meticulous investigation in cases of unusual speech disorders, especially in complex clinical contexts such as the one presented, in order to guide clinical management and provide better results for patients affected by this unusual syndrome.

Correspondence: Mariana de Almeida Cruz Silva; Email: mariana.almeida20021@gmail.com.

Background: Hemifacial spasm (HFS) is a movement disorder marked by involuntary facial muscle contractions, often due to a nearby blood vessel pressing on the facial nerve. Typically, HFS onset occurs between the fourth and sixth decades of life and has an annual incidence of 0.78 per 100,000, being considered a rare disorder. Botulinum toxin type A (BoNT-A) stands as the gold-standard therapy in the treatment of HFS. The presence of facial pain associated with HFS is commonly observed in clinical practice, although there is still little research on the subject. **Objective:** To characterize facial pain patterns in patients with HFS by evaluating the location, frequency, intensity, and duration of pain, as well as its relation to BoNT-A injections. **Methods:** A cross-sectional study was conducted with 53 HFS patients (F: 35, M: 18) at a public tertiary hospital over 6 months. The average age was 66.1 years (SD 12.2). Patients with cognitive impairment, BoNT-A use in the last three months, and other movement disorders were excluded. Data were collected using sociodemographic and structured facial pain questionnaires, the McGill Pain Questionnaire, and the HFS-Score for quality of life. Statistical analyses were performed using Epi Info software. **Results:** Among the 53 patients, 23 (43%) reported facial pain. The most common location was the periorbital region in 17 cases (65%), followed by maxillary region in 4 patients (15.3%), mandibular in 2 patients (7.6%), and auricular, whole hemiface and bilateral palpebra in 1 case (3.8%) each. All patients described pain ipsilaterally to the spasm side, and 1 patient described pain involving palpebral areas bilaterally. Spasms were present on the left side of the face in 33 (62%) patients. The average pain intensity was 6.1 on the Visual Analog Scale (VAS) (SD 2.1), with a mean frequency of 8.6 (SD 7.7) days/month and 2.3 (SD 2.3) episodes/day, lasting an average of 9.6 hours (SD 10). The average time to pain onset after HFS motor symptoms was 9.9 years (SD 9). Twenty patients reported that previous BoNT-A applications improved facial pain, while the remaining three reported no change. No patient reported a perception of worsening pain after BoNT-A injections. Although facial pain was frequently reported by the patients, no statistically significant difference was found between the severity of facial pain and the quality of life among individuals with HFS (p value 0,1993). The most common descriptors for the facial pain were: pulling (11 patients), itchy (10 patients), annoying (10 patients), miserable (9 patients), pinching (9 patients) **Conclusion:** This study highlights the need to investigate and treat facial pain in patients with hemifacial spasm, a rare and debilitating condition. Analyzing pain patterns and the efficacy of botulinum toxin treatment underscores the importance of tailored therapeutic approaches and guides future research.

Background: Dominantly inherited GAA repeat expansions in intron 1 of the fibroblast growth factor 14 (FGF14) gene have recently been found to be a common cause of hereditary adult-onset cerebellar ataxia (GAA-FGF14 ataxia; spinocerebellar ataxia 27B). The global epidemiology and regional prevalence of this newly reported disorder remain to be established. **Objective:** We here investigated the frequency of GAA-FGF14 ataxia in a large

cohort of Brazilian patients with unsolved adult-onset cerebellar ataxia. **Methods:** We recruited 93 index patients with genetically unsolved adult-onset cerebellar ataxia despite extensive genetic investigation and genotyped the FGF14 repeat locus. Patients were recruited across 4 different regions of Brazil. **Results:** Of the 93 index patients, 8 (9%) carried an FGF14 (GAA)≥250 expansion. The expansion was also identified in one affected relative. Seven patients were of European descent, one was of admixed American ancestry, and one was of African descent. One patient carrying a (GAA)376 expansion developed ataxia at age 28 years, confirming that GAA-FGF14 ataxia can occur before the age of 30 years. One patient displayed episodic symptoms, while none had downbeat nystagmus. Cerebellar atrophy was observed on brain MRI in 7 of 8 patients (87%). **Conclusion:** Our results suggest that GAA-FGF14 ataxia may be a common genetic cause of adult-onset cerebellar ataxia in the Brazilian population, although larger studies are needed to fully define its epidemiology.

From independent to incapacitated: a case of antiepileptic drug-induced rapidly progressive dementia

Guilherme Lago Miranda[1], Amanda Freitas Alves[1], Ingrid Lorena da Silva Gomes[1], Matheus Reis Rosa[1], Giovanni Caniçali Simões[1], Henrique de Moraes Bernal[1], Roberta Arb Saba Rodrigues Pinto[1], Marcele Schettini de Almeida[1], Herval Ribeiro Soares Neto[1], Camila Hobi Moreira[1]

[1]Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo SP, Brazil.

Correspondence: Guilherme Lago Miranda; Email: lagomiranda.g@gmail.com.

Case presentation: A 76-year-old woman, previously independent in instrumental activities of daily living, diagnosed with epilepsy at age 12, was taking irregularly phenytoin 200mg/day and phenobarbital 200mg/day. Approximately 4 months prior, her family assumed the task of medication intake, so she started to use it as prescribed. In two months, she developed progressive cognitive decline, difficulty walking and insomnia. She was admitted to the emergency room due to a significant worsening of her condition over the past 2 weeks, with a reduced level of consciousness, verbalizing only incomprehensible sounds and unable to eat. On neurological examination, the patient was torporous, showed no motor response to pain, and showed neither pyramidal signs nor involuntary movements. Faced with the hypothesis of rapidly progressive dementia (RPD), extensive further investigation took place. Her cerebrospinal fluid showed the presence of 1 cell, 53 proteins and 67 glucose. Brain MRI had no abnormalities, and her EEG showed an excess of diffuse beta activity. Neoplastic investigation and a serum onconeural panel were unremarkable. Phenobarbital serum concentration was above 80 (reference value 15-40). Therefore, the medication was withdrawn without tapering. Phenytoin was on normal range. A short course of high-dose steroid therapy was also performed for the possibility of immune-mediated encephalitis, despite non-suggestive complementary tests. The patient started to gradually improve, being discharged able to walk with assistance and on oral feeding, and without immunosuppressants. At the most recent outpatient follow-up, 8 months later, her status was restored, with good seizure control with lamotrigine, and her phenobarbital serum concentration was zero. **Discussion:** Drug-induced reversible dementia can occur in the context of excessive use, polypharmacy and side effects. The antiepileptic drugs most commonly associated with this condition are phenytoin and valproic acid, but there have been reports in the literature of RPD in patients using phenobarbital in combination with lithium and levomepromazine. Phenobarbital is a barbiturate that enhances the GABAergic effect by prolonging the opening of chloride channels. Serum levels above 50 to 60ug/ml can lead to progressive neurological dysfunction and decreased level of consciousness leading up to coma. The interaction between the two first-generation antiepileptics she was on might have caused the intoxication. As suggested in the literature, we also initiated empirical treatment with corticosteroids due to the severity of her condition, but no other immunosuppressive treatment was maintained, and the patient continued to show progressive improvement with the discontinuation of the anticonvulsant and gradual decrease in serum medication levels. **Final comments:** Toxic-metabolic and iatrogenic RPD etiologies should always be thoroughly investigated and ruled out, given their potential reversibility.

From reversible cerebral vasoconstriction syndrome to subarachnoid hemorrhage, a continuum presentation of the same pathology: a case report associated analgesic abuse in kidney transplant recipient

Renato Dumbá Monteiro de Castro[1], Amanda Fernandes Klajn[1], Sacha Allebrandt da Silva Ries[1], Taís Luise Denicol[1], Alexandre Laisson Prado Taschetto[1], Carolina Matté Dagostini[1], Juan Sebastián Sánchez León[1], Pedro Hall Ruschel[1], Cândida Driemeyer[1], Liselotte Menke Barea[1]

[1]Santa Casa de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Renato Dumbá Monteiro de Castro; Email: renato.castro@ufcspa.edu.br.

Case presentation: Female patient, 61 years old, admitted to the emergency department reporting the onset of new pulsating headache with severe intensidade (visual analog scale 9/10) 5 days ago, bilateral, parietooccipital region, partial relief after use of analgesics, lasts more than 24 hours with recurrence and increasing intensity when taking a shower, accompanied by nausea and dizziness at the peak of pain without visual changes. Previously diabetic and kidney transplant 17 years ago by polycystic kidneys. In regular use of metformin, 1000mg/day, sirolimus 2mg/dia (macrocyclic lactone class immunosuppressant), predinisone 10mg/day, Gabapentina 300mg/day for facial postherpetic neuralgia and intermittent tramadol 100mg 4 to 6 times a week for 4 months due to ankle tendinopathy. Secondary headaches were investigated and the initial tomography angiography showed focal areas of luminal narrowing in bilateral middle cerebral arteries, M2/M3, and posterior cerebral arteries, P2/P3, suggestive of vasoconstriction. No aneurysmal formations or hematological content were identified. Laboratory tests were normal and liquor analysis with hematic macroscopic appearance identified an increasing red blood cells (RBC) in two consecutive samples, ruling out puncture accident. The first collection showed bottles 1, 2 e 3 with erythrocyte count of 4480, 5800 and 6400 , respectively. Second confirmatory sample in bottles 1 and 2 with RBC of 4800 and 11200. Given the suspicion, potential drug causes were suspended and replacement of the immunosuppressive class. Administered vasospasm preventive drugs , such as nimodipine 360mg/day. Complementary investigation magnetic resonance of the vessel wall without parietal enhancement reinforced the suspected reversible cerebral vasoconstriction syndrome (RCVS). After 10 days followed by neurological surveillance in the intensive care unit and transcranial echodoppler monitoring, she presented a focal neurological deficit with paresis of the right upper limb. A new control with digital subtraction angiography ruled out microaneurysms and intracranial milrinone was administered to endovascular hoping to control vasospasms, in addition to clinical drug support and euvolemia maintained for 21 days, according to the best recommendations in current medical literature still scarce. **Discussion:** RCVS is widely described in lists of association with specific drug induction. However, complications such as SAH, vasospasm and pathophysiological progression still require details so that prevention and therapeutic procedures can be protocoled with quality scientific evidence. **Final comments:** Cases of headache suggestive of a secondary cause and clinical presentations with their red flags are frequent complaints in neurological care. Recognizing the main etiologies can prevent complications. Therefore, it is important to disseminate presentations and less common pathological progress among health care professionals and scientists.

Frontotemporal dementia (FTD) and amyotrophic lateral sclerosis (ALS): is clinical diagnosis sufficient? A case report

Wellington Costa da Silva Filho[1], Helton Benevides Santana de Oliveira[1], Renê Vasconcelos Silva[1], Gabriel Ribeiro Andrade Neto[1], Myllena Maria Santos Santana[1], Jorge Dornellys da Silva Lapa[1], Flávia Barreto Garcez Carvalho[1], Roberto César Pereira Prado[1]

[1]Universidade Federal de Sergipe, Aracaju SE, Brazil.

Correspondence: Helton Benevides Santana de Oliveira; Email: heltonbenevides@vidaampla.com.br.

Case presentation: An 84-year-old hypertensive patient began experiencing dysarthria and progressive dysphagia in 2020. One year later, notable behavioral changes emerged, characterized by aggressiveness, agitation, and disinhibition. These behaviors included repetitive folding and unfolding of clothes, public lifting of her skirt, and attempts to attack family members with a weapon. Notably, these symptoms manifested without significant memory impairment. Neurological examination revealed motor aphasia, paralysis of the orbicularis oris and right eye muscles, jaw drop, atrophic tongue with fasciculations and immobility, and reduced muscle strength (grade 4+) in the right hemibody and left lower limb, and grade 4 in the left upper limb. Fasciculations were observed in the left deltoid and right quadriceps. Deep tendon reflexes were hyperactive, and there was a questionable plantar response on the right. Electromyography indicated axonal degeneration with chronic reinnervation signs in the C5, C6, C7, C8, T1, L4, L5, and S1 myotomes bilaterally, active denervation in the tongue muscles and left C8/T1 myotomes, and no sensory abnormalities. **Discussion:** Motor neuron disease may precede or follow the onset of FTD, often presenting as the behavioral variant. In patients with classical amyotrophic lateral sclerosis (ALS), characterized by neuromuscular symptoms, 15 to 20% also exhibit cognitive and behavioral symptoms consistent with FTD, particularly the behavioral subtype. These patients frequently present with bulbar symptoms more prominently than those with classical ALS. A hexanucleotide repeat expansion in the C9orf72 gene is the most commonly identified genetic cause of the combined FTD and ALS presentation, accounting for approximately 5-10% of sporadic ALS cases. Other implicated genes include the autosomal dominant FUS gene, responsible for about 2% of sporadic cases, and the rarely recessive TARDBP gene. In this case, the diagnosis of ALS is confirmed by electromyography according to the El Escorial criteria. The 2011 criteria of the International Behavioral Variant FTD Criteria Consortium (FTDC) suggest possible frontotemporal dementia. **Final comments:** While most patients with FTD do not initially exhibit significant motor symptoms, these can precede the onset of dementia and may result from frontotemporal lobar degeneration. Patients with concurrent FTD and ALS have a shorter survival than those with isolated FTD. Given the strong association of FTD-ALS with the C9orf72 gene expansion, alongside other known genetic factors, genetic testing is recommended but not mandatory for diagnosis.

Background: Mild cognitive impairment (MCI) is characterized by a decline in multiple cognitive domains without significant impairment in daily living activities. The pathophysiology of MCI involves abnormal brain network connectivity patterns, particularly in fronto-medial regions responsible for memory processing, attention, and linguistic and visuospatial comprehension. These include the auditory, language, sensorimotor, vision, visuospatial, and basal ganglia networks. While physical exercise has been shown to slow the progression of MCI by enhancing brain connectivity, the specific impact of resistance training (RT) on MCI remains a relatively unexplored area of research. **Objective:** To investigate the impact of 24 weeks of RT in patients diagnosed with MCI on the functional brain connectivity (FC) of the auditory, language, sensorimotor, vision, visuospatial, and basal ganglia networks. **Methods:** 37 older adults diagnosed with MCI (NIA and Alzheimer's Association 2018 criteria) were selected and divided into a training group (N=19) and a control group (N=18). The training group performed a 24-week RT protocol based on exercises for large muscle groups. All subjects underwent Magnetic Resonance in an Achieva 3T PHILIPS. FC data from the auditory, language, sensorimotor, vision, visuospatial, and basal ganglia networks were evaluated before and after the intervention using seed-based resting-state functional MRI (fMRI) methods (UF2C toolbox running on MATLAB software). Statistical analysis was conducted using a paired t-test, considering all the ROIs evaluated. Significance was set at $p<0.01$, uncorrected for multiple comparisons. **Results:** Our analysis of the training and control groups revealed increased connectivity in the visuospatial network (T-score> 2.7195, $p<0.01$, uncorrected) in the training group. No differences in FC were found in the control group. These findings indicate a potential positive effect of RT on the functional connectivity of the visuospatial network in MCI patients. **Conclusion:** Our findings suggest that RT might have improved the functional connectivity of the visuospatial network, which may help enhance visuospatial skills in patients at risk for dementia. More clinical studies of longer duration are required to determine its role in controlling symptoms and progression to the dementia stage and to search for other affected areas.

Functional recovery following resections of focal cortical dysplasia for epilepsy in the primary motor cortex (M1)

Eliseu Paglioli[1], Rafael Paglioli[1], William Martins[1], Fernanda Schuh Martins[1], Vicenzo Zarpellon[1], Thomas Frigeri[1], Victoria Bizzi Schvartzman[1], Natalie Donida[1], Bibiana Thome[1], André Palmini[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Victoria Bizzi Schvartzman; Email: bizzivictoria@gmail.com.

Background: Focal cortical dysplasias (FCD) occasionaly localize to functionally relevant regions in the primary motor cortex (M1), and resections inevitably lead to motor deficits, with variable degrees of recovery. **Objective:** The available literature reports functional outcomes in groups of patients, but lacks precision when these data must be applied to counselling individual patients. **Methods:** In this study we present the motor evolution following focal resections in the hand (#1) and foot (#2) areas of M1 over several weeks in 2 patients with FCD and daily (often prolonged or recurring) seizures. Patients and methods: A 30yo woman (#1) and a 13 yo boy (#2) with small FCDs in the M1 hand and foot area, respectively, underwent lesional resection, preserving the vascular supply of the underlying white matter. Examinations of sensori-motor functions were performed daily in the first post-operative week. Subsequently, patients were evaluated through simple tests at home with video documentation. Both are on intensive programs of physical therapy. **Results:** Preoperatively, both had some degree of weakness, that fluctuated according to seizure frequency. Following resections, both were fully plegic of the hand or foot for 3 days, yet after one week patient #1 could performed discrete global finger flexion, followed by exponential recovery in the following weeks. Six weeks later she could perform flexion of the wrist and is quickly improving on fine finger movements and extension of the wrist. The boy (#2) began to walk without assistance on post-op day 7-, and 3-weeks following surgery was with better functionality than previous to surgery, as seizures stopped and there were no further functional worsening thus related. Both had complete seizure control. **Conclusion:** Focal resections of FCD in M1 may control intensely refractory seizures with expressive functional recovery over weeks, following a transitory period of focal plegia. Crucially, the underlying white matter must be carefully preserved.

Functional/dissociative seizures in the pediatric/hebiatric population: videoelectroencephalography results from Santa Casa de Belo Horizonte

Vivian Proença Lara[1], Glaucia Monteiro Oliveira[1], Igor Pereira Matos de Oliveira[1], Caio Cobucci Esteves[1], Ana Luíza Xavier Drumond[1], Luiza Barbosa de Oliveira[1], Vanessa Alves Lobato[1], Aline Curcio de Moraes[1], Helena Barbosa Horta Santos[1], Maria Do Carmo de Vasconcellos Santos[1]

[1]Santa Casa de Belo Horizonte, Belo Horizonte MG, Brazil.

Correspondence: Vivian Proença Lara; Email: vi.prlara@gmail.com.

Background: Functional/dissociative seizures (FDS) are episodes that may resemble epileptic seizures but lack abnormal brain electrical activity. They have been described mainly in adults and less frequently in the pediatric/hebiatric population. Clinical diagnosis may be difficult, even for specialists. The gold standard is videoelectroencephalography (VEEG), not avaliable in all centers. This exam is able to distinguish between FDS and epileptic events and target proper treatment. **Objective:** To provide a descriptive analysis of clinical characteristics (age, sex, concomitant epilepsy, use of antiseizure/psychotropic medication and semiology) of patients under 20 years old with FDS from our VEEG unit and to compare the results with literature. **Methods:** Medical and VEEG records of patients aged 0-19 years (defined as child and adolescent by World Health Organization) were analyzed. All of them had at least one functional event recorded during monitoring between january/2020 and may/2024 at Santa Casa de Belo Horizonte. Epilepsy was defined by abnormal eletroencephalography or structural lesions in brain image exams. **Results:** 296 VEEG were performed on children and adolescents during the period mentioned in our service. Of these 19 presented FDS during the monitoring (6.4% of the total) which is in accordance with prevalence of 3.5% to 20% already described. The average age was 16 years (higher than in the population without FDS, whose average was 10). Furthermore 78.9% were female (compared to 44.4% in those without functional events). Both information are in agreement with the literature that shows higher frequencies of FDS in adolescents (compared to children) and in females. 63.2% didn't have concomitant documented epilepsy; in this subgroup 83.3% was using antiseizure medication due to the fact that they were diagnosed on an outpatient basis as epileptic before the VEEG investigation, showing frequent diagnostic difficulties. 58.3% of the group without epilepsy was using psychotropic drugs. We didn't know if they were following a psychological treatment. In relation to the semiology of FDS, 78.9% showed non-synchronized movements in the video, 57.9% forced eye closure, 52.6% immediate return to the baseline state, 42.1% behavioral arrest, 42.1% side-to-side movement of the head, 15.8% arched lumbar position and 10.5% seizures lasting more than 2 minutes. These signs are usually described as having high specifity for FDS. One of the children presented the "teddy bear sign" which is controversial in literature. **Conclusion:** This work is in line with previous studies that shows FDS are relatively common events, even in the pediatric/hebiatric population and that they are many times misdiagnosed. The accuracy of assessing these events early is essential for adequate clinical management of patients. Also expertise for physicians who diagnose and manage these disorders in children and adolescents is needed.

Functionality and disability according to whodas 2.0 in people with stroke: a cross-sectional study

Paloma Rodrigues da Silva[1], Daniel de Sá Horácio Pereira[1], Rebeka Amanda Dias[1], Júlia Teixeira Magalhães[1], Leonardo Barcellos[1], Maria Elisa Pimentel Piemonte[1]

[1]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Paloma Rodrigues da Silva; Email: paloma.rsilva@usp.br.

Background: The International Classification of Functioning, Disability, and Health (ICF) describes functionality as the positive aspects of the interaction between an individual (with a health condition) and their contextual factors (environmental and personal). It considers functionality as the third health indicator, complementing previous indicators of morbidity and mortality. The World Health Organization Disability Assessment Schedule 2.0 (WHODAS 2.0) is a universal assessment tool created by WHO, based on the ICF, to provide a standardized method for measuring the impact of any health condition on functionality and disability across different cultures. A stroke (cerebrovascular accident) can cause numerous changes across various dimensions of an individual's functionality. **Objective:** To characterize the changes in functionality according to WHODAS 2.0 in individuals who experienced a stroke. **Methods:** A cross-sectional study conducted according to STROBE guidelines, with 37 participants (20 men)

with a mean age of 67.67±13.7, diagnosed with ischemic or hemorrhagic stroke. Inclusion criteria were: (1) age 18 years or older; (2) diagnosed with ischemic or hemorrhagic stroke based on imaging; and (3) patient or guardian capable of providing informed consent and completing the questionnaire. Exclusion criteria were: (1) history of stroke more than one year ago or less than six months ago; and (2) presence of other neurological conditions such as Parkinson's or Alzheimer's disease. Participants were assessed in person by trained physiotherapists using WHODAS 2.0 to evaluate functionality and disability levels. **Results:** The WHODAS 2.0 total scores were 71.62±27.2. Total scores were not correlated with age, schooling, or type of stroke. The most affected functionality dimensions were life activities related to household (51.75%), mobility (48.75%), and participation (47.97%). Only 8 participants returned to work activities and obtained scores for this dimension (44.79%). **Conclusion:** These findings have important implications for patient care and management. Characterizing the different affected dimensions of functionality should be considered when conducting and adapting pharmacological and nonpharmacological interventions for people with chronic sequelae of stroke accordingly.

Fungal encephalitis by Kluyveromyces marxianus (Candida kefyr) associated with pyelonephritis in an immunocompetent patient

Kauan Alves Sousa Madruga[1], João Felipe Guimarães Santos[1], Luis Paulo Machado Scalise[1], Fernanda Alcântara Nascimento Aguiar[1], Valdecir Boeno Spenazato Júnior[1]

[1]Santa Casa de Misericórdia de Barretos, Barretos SP, Brazil.

Correspondence: Kauan Alves Sousa Madruga; Email: kauanmbr@gmail.com.

Case presentation: This case report details a 37-year-old immunocompetent woman from Barretos, SP, previously controlled for hypertension, who presented with refractory right hip pain, fever, right flank pain, confusion, disorganized speech, fluctuating episodes of myoclonus, migrainous headache, occasional unexplained laughter, and a single visual hallucination. Hospitalized on May 3, 2024, at Santa Casa de Barretos, initial treatment targeted urinary tract infection with ceftriaxone. Neurological evaluation revealed intentional tremor worse on the right, frontal release signs, recent anterograde amnesia, and anomia. Diagnostic hypotheses included encephalitis associated with pyelonephritis/sepsis, prompting cerebrospinal fluid (CSF) puncture, cranial CT, and MRI. Empirical treatment with acyclovir, ceftriaxone (CNS dose), and dexamethasone was initiated but showed no clinical improvement. CSF analysis revealed hyperproteinorrachia, hypoglycorrhachia, and lymphocytic pleocytosis, suggestive of fungal encephalitis despite negative fungal serologies and culture. Infectious disease consultation advised repeat CSF sampling, broadening the investigation to include acid-fast bacilli, MTB-RIF (molecular tuberculosis rapid test), viral panel, fungal culture, and escalated antibiotic therapy (ampicillin and amikacin), alongside continued acyclovir for 21 days. Persistent clinical decline led to a repeat MRI showing findings indicative of fungal encephalitis, confirmed by positive urine culture for kluyveromyces marxianus. Empirical treatment with amphotericin B for CNS was commenced, resulting in significant improvement in consciousness level and CSF parameters after one week. Discharge planning included fluconazole therapy with scheduled serial imaging and CSF exams to guide future medication discontinuation. Ongoing CSF fungal culture is pending. Fungal CNS infections, including fungal encephalitis, are particularly challenging due to their dependence on host immune status and the virulence of the fungal strain involved. These infections often lead to substantial morbidity in immunocompromised individuals and can result in severe, potentially fatal neurological outcomes. This case highlights the unusual occurrence and diagnostic hurdles of fungal encephalitis in immunocompetent patients, originating from a primary urinary tract infection. The timely initiation of empirical antifungal therapy with amphotericin B, despite initial negative cultures, played a critical role in achieving clinical improvement. Given the intricate diagnostic and therapeutic landscape, further investigation into the diverse etiologies of encephalitis, including fungal infections in immunocompetent individuals, is crucial for optimizing patient outcomes.

Correspondence: Andre Felipe Candêas Amorim; Email: andfcamorim@gmail.com.

Case presentation: A 68-year-old man began to experience significant apathy and after approximately 15 days evolved with episodes of focal to bilateral tonic-clonic epileptic seizures. The patient was previously hypertensive, diabetic and an active smoker with a smoking history of 50 pack-years. He was initially seen at an external service and, after MRI and cerebrospinal fluid collection, the hypothesis of herpetic encephalitis was suggested. He was treated with 14 days of acyclovir and anti-seizure medication was started, which improved the epileptic seizures. Nevertheless, the patient remained apathetic and started to experience delirium and visual hallucinations. In our service, the hypothesis of autoimmune encephalitis was raised, and the patient underwent a head MRI which showed hypersignal on T2/FLAIR in the hippocampus and right uncus associated with slight edema. The patient's CSF showed pleocytosis with 42 cells/mm^3 with lymphomonocyte predominance, protein 69 mg/dL, glucose 55mg/dL, negative infectious tests and a negative viral panel. The antibody panel for autoimmune encephalitis revealed positivity for GABA-B The patient underwent treatment with pulse therapy with methylprednisolone 1g/day for 5 days and then received human immunoglobulin 2g/kilo distributed over 5 days. The patient evolved with complete improvement of psychiatric symptoms, however he remained dependent on anti-seizure drugs. During neoplasia investigation, small cell lung carcinoma was diagnosed, and the patient began treatment with chemotherapy while still hospitalized. **Discussion:** GABA-B encephalitis is associated with the phenotype of limbic encephalitis, epilepsy, rapidly progressive dementia, and ataxia. Half of the cases are usually paraneoplastic manifestations and generally associated with small cell lung carcinoma.. The main differential diagnosis of the case mentioned is herpetic encephalitis, which should always be considered due to its severity. In these cases, head MRI (herpes usually shows more significant edema, generally unilateral, more significant white matter involvement and a greater chance of changes on DWI) and CSF with a viral panel can help in managing the cases. **Final comments:** It is extremely important for neurologists to know about autoimmune encephalitis, its clinical manifestations and its treatment. It is worth mentioning that such diseases are potentially treatable causes of encephalitis, and may even be the first manifestation of an undiagnosed neoplasm.

GAD-linked cerebellar ataxia and chronic use of phenytoin

Lucas Medeiros Dunga[1], Matheus Procópio Guimarães[1], Tereza Cristina Batista Dias[1], Fabricia dos Santos Almeida[1], Amanda Lima Sampaio[1], Lucca Ferdinando Queiroz Fernandes[1], Cláudio de Souza Fernandes Júnior[1], Pedro Henrick Guimarães Carvalho[1], Iury Hélder Santos Dantas[1], Helmut Kennedy Azevedo Do Patrocínio[1]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.

Correspondence: Lucas Medeiros Dunga; Email: lucasdunga2000@gmail.com.

Case presentation: Patient MFBA, female, 45 years old, with a history of epileptic seizures that began in 2018, on chronic use of phenytoin (300 mg/day) since diagnosis. In 2022, she started experiencing imbalances associated with falls. At the first consultation, the patient was unable to walk without support, needing assistance. She had already been evaluated by otolaryngologists and psychiatrists. She denied diarrhea, recent infections, and had never had COVID-19 (received the Oxford and Pfizer vaccines). Comorbidity: hypothyroidism, using Puran 25 mcg. Muscle strength was G5 globally, except in the proximal muscles of the lower limbs (G4). Tendon reflexes were brisk in the upper limbs and absent in the lower limbs, with a bilateral extensor plantar response, without clonus. Motor coordination without dysmetria and diadochokinesia. Sensitivity without sensory level, with anesthesia in the lower limbs and preserved pressure sensation, hypopalesthesia in the right lower limb and apalesthesia in the left lower limb, proprioception absent on the left and reduced on the right. Balance with positive Romberg and ataxic gait. With the withdrawal of phenytoin and replacement with levetiracetam, there was a partial improvement in imbalance and falls. Cranial MRI revealed cerebellar folia atrophy. Antibody test showed anti-GAD greater than 2000IU/ml, normal vitamin E (5.9), elevated anti-thyroperoxidase antibodies (>1300, NR <60), anti-thyroglobulin 27.3 (NR <6.5) and positive ANA with a dense fine speckled pattern 1/320. Serologies for HIV, VDRL, hepatitis B and C were negative. The patient presented a medical picture that suggested a cytokine storm due to alterations in various autoimmune tests. The patient showed significant clinical improvement, being able to walk more independently, although with a cautious gait. The patient was referred for evaluation with a rheumatologist and suggested to undergo electromyography (EMG) and cerebrospinal fluid (CSF) examination, in addition to being directed to the ataxia clinic at HUOL for continuous follow-up. **Discussion:** The patient presented a condition that was compatible with an cytokine storm, manifested by several autoimmune changes and cerebellar ataxia, probably exacerbated by the chronic use of phenytoin. Withdrawing the drug and replacing it with levetiracetam brought a significant improvement in the clinical picture, suggesting that phenytoin toxicity could be contributing to the ataxia. **Final comments:** This case highlights the importance of considering the long-term adverse effects of antiepileptic medications, such as phenytoin, in patients presenting new neurological symptoms. However, it indicates how symptoms of autoimmunity can be masked with the use of inappropriate medications in the treatment of epilepsy.

https://doi.org/10.5327/CBN240824

Gamma-delta T cells suppress microbial metabolites that activate striatal neurons and induce repetitive/compulsive behavior in mice

Laura M. Cox[1], Bruna K. Tatematsu[1], Danielle S. Leserve[1], Thais G. Moreira[1], Marília G. de Oliveira[1], Ana C. Rosa[1], Roberta C. Fonseca[1], Andre G Oliveira[2] , Howard L. Weiner[1], Rafael M. Rezende[1]

Correspondence: Ana Clara Rosa Coelho Guimarães; Email: anaclararcg@gmail.com.

Intestinal γδ T cells are crucial for maintaining the gut microbiota homeostasis, which significantly influences brain function and behavior. Abnormalities in gut microbiota have been associated with conditions such as autism and depression, yet the specific mechanisms remain unclear. Here, we show that mice lacking γδ T cells (γδ -/-) developed a pattern of repetitive/compulsive (R/C) behavior that was characterized by repeated jumping and increased number of buried marbles as compared to wild type (WT) littermate controls. R/C behavior was associated with the activation of the striatum, but not with other brain areas, as measured by increased number of cells positive for the transcription factor FosB/ΔFosB. Moreover, co-expression of FosB/ΔFosB and NeuN, a specific neuronal marker, indicated that neurons, rather than non-neuronal cells were critical for γδ -/- mouse repetitive behavior. We then investigated the mechanisms by which γδ -/- mice developed R/C behavior and found that the gut microbiota played a critical role, since γδ -/- mice colonized with WT microbiota no longer had repetitive behavior and WT mice colonized with γδ -/- microbiota developed repetitive behavior. Importantly, by performing a large-scale metabolomic analysis, we identified the microbial metabolite hippurate (HIP), a glycine conjugate of benzoic acid formed through gut bacterial metabolism of aromatic amino acids, to be highly increased in the stool, serum and cerebrospinal fluid (CSF) of γδ -/- mice. To investigate whether HIP induced R/C behavior in WT mice, we treated mice with HIP and found that it induced R/C behavior similarly to what we found in γδ -/- mice. Moreover, WT mice treated with HIP showed increased activation of striatal neurons. To investigate which striatal neurons responded to HIP by upregulating FosB/ΔFosB, we performed RNAscope in situ hybridizatio of WT mouse striatum after treatment with HIP. We used Fosb, Drd1a (dopamine type 1 receptor; D1R) and Drd2 (dopamine type 2 receptor; D2R) probes to investigate whether medium spiny neurons, the most abundant neuronal type in the striatum, were involved in this process. We found that the majority of FosB+ cells in the striatum co-expressed D1R after HIP treatment, suggesting that HIP dysregulates striatal circuits associated with D1R+ MSNs. Notably, culture of striatal slices in the presence of HIP or the D1R selective agonist dihydrexidine hydrochloride (DIH) led to similar c-Fos expression in striatal neurons. Accordingly, the use of a D1R selective antagonist abolished this effect, indicating that HIP induces R/C behavior by activating D1R expressed on D1R+ MSNs and thus by dysregulating the direct pathway of the cortical-striatal-basal ganglia-thalamic circuit. Altogether, these data suggest that intestinal γδ -/- T cells shape the gut microbiota and their metabolites and prevent dysfunctions of the striatum associated with behavior modulation.

Ganglionopathy and leprosy: a rare clinical presentation or overlapping pathologies?

Stefano Machado[1], Iago Resende Carvalho[1], Arthur Costa Nascimento[1], Isabela Maria Bernardes Goulart[1], Diogo Fernandes dos Santos[1]

[1]Universidade Federal de Uberlândia, Hospital de Clínicas, Uberlândia MG, Brazil.

Correspondence: Stefano Machado; Email: stefanomachadomed@gmail.com.

Case presentation: A 52-year-old man with a progressive asymmetrical sensory deficit for several years was diagnosed in 2016 with borderline tuberculoid leprosy. He was treated with the multibacillary polychemotherapy regimen, achieving cure criteria in 2018. However, presented some episodes of leprosy neuritis after the end of treatment. In 2023, subacutely (over a period of 4-8 weeks), he experienced sensory worsening and postural instability and subsequently developed a decrease in visual acuity, both progressive. The clinical evaluation revealed xerophthalmia, xerostomia, mydriatic and hyporeactive pupils, thermal and pain hypoesthesia in distal segments (with an asymmetrical pattern, also with greater impairment of cold areas), apalesthesia, global areflexia, ataxic gait and presence of Romberg sign. Faced with a new condition of sensory ataxia, electroneuromyography was performed, demonstrating absences of all sensory nerve action potentials evaluated (median, ulnar, radial, superficial peroneal, and sural) with an asymmetric axonal motor impairment (already observed in previous evaluation). An extensive laboratory evaluation was carried out, including metabolic, hormonal, serological and deficiency screening - serum and CSF - which showed no pathological changes. Furthermore, given the possibility of a paraneoplastic condition, an investigation for neoplasia was carried out, but there were no changes. Investigation of inflammatory diseases showed no changes. However, the Schimmer test and salivary flow assessment confirmed the presence of xerophthalmia and xerostomia. Based on the results of the investigation, a diagnosis of ganglionopathy secondary to Sjogren's Syndrome was made and immunosuppressive treatment was started with an excellent response and significant improvement after the Cyclophosphamide infusion. **Discussion:** Leprosy neuropathy is extremely common and prevalent, especially in underdeveloped countries. It commonly presents as a multiple mononeuropathy, classically with sensory predominance (truncal and/or intradermal), rarely with signs of sensory ataxia, even in cases of long evolution. Proximal involvement of the peripheral nervous system (dorsal root ganglion, brachial plexus, and motor roots) and even the central nervous system (medullary) have already been described in some cases in the literature. However, there are still doubts regarding the mechanism of injury, which may be related to direct aggression by M. leprae to these structures or be related to an immune-mediated process. **Final comments:** Ganglionopathy is usually caused by paraneoplastic, autoimmune, genetic, toxic, deficiency, and infectious conditions. Despite being a rare presentation, it may be present in the context of leprosy, especially in multibacillary cases, during episodes of leprosy reaction. Otherwise, leprosy is a systemic inflammatory disease and can trigger the development of other rheumatological diseases.

Gene expression analysis of the WNT and mtor pathways from brain tissue of patients with focal cortical dysplasia type II

Douglas Bottega Pazzin[1], Thales Thor Ramos Previato[1], Marina Ottmann Boff[1], Fernando Xavier[1], Daniel Rodrigo Marinowic[1]

[1]Instituto do Cérebro, Porto Alegre RS, Brazil.

Correspondence: Marina Ottmann Boff; Email: mottmannboff@gmail.com.

Background: Focal cortical dysplasia (FCD) is the most common malformation of cortical development to cause drug-resistant epilepsy (DRE) in children and adults. The origin of the malformation in FCD remains unknown. Changes in the gene expression profile may be responsible for alterations in cell responses and tissue malformations. The PI3K/AKT/mTOR pathway is the main one related to type II FCD and is modulated by the WNT pathway. The WNT and mTOR pathways are responsible for signaling related to cell differentiation, apoptosis, and migration in different tissues, fundamental for corticogenesis. The main treatment for ERDs is resection of the epileptogenic zone, with an efficacy of 60-80% for DCF II (complete seizure control with anti-epileptogenic drugs (AED)). Seizure control has been reported in patients with ERD using AED adjunct to mTOR inhibitors. It is therefore of interest to investigate potential new targets related to the formation of these epileptogenic zones in FCDs. **Objective:** Evaluation of the expression of WNT and mTOR pathway genes in patients with Focal Cortical Dysplasia type II. **Methods:** The groups were divided into control (healthy cortex tissue), acquired from surgery for hippocampal resection; focal cortical dysplasia IIa; and focal cortical dysplasia type IIb. From these samples, genetic material was extracted and amplified to observe expression levels of 16 genes involved in the WNT pathway and 3 in the mTOR pathway through qPCR. Amplification values were analyzed by relative expression using the formula: 2(-ΔΔCt). The values found were distributed in a heat map following the Pearson correlation. **Results:** Using relative expression values, a greater change in hyperexpression was identified for WNT genes in patients with FCD IIb to group IIa. The type IIa FCD group showed a decrease in expression for 7 WNT genes and 1 mTOR gene, while the type IIb FCD group showed increased expression for all 16 WNT genes and 2 mTOR genes. The increase in expression in the mTOR and RHEB genes is consistent with patterns in the literature for increased mTOR activity in patients with type II FCD, however, it was possible to identify a clear difference in expression profile between these diseases when analyzing WNT. The evaluation of Peason's correlation presented a strong positive correlation among all WNT pathway genes for FCD IIa, compared to 14 genes with a strong positive correlation and 2 with a strong negative correlation for FCD IIb. **Conclusion:** These data showed a specific relationship between type II FCD and changes in the WNT pathway, in addition to a distinct expression profile between the two types of the disease, with different expression correlations, enhancing assistance in post-surgical diagnosis.

Gene therapy for Duchenne muscular dystrophy in Brazil: a case report

Clara Gontijo Camelo[1], Felipe Franco da Graça[2], Mariana Cunha Artilheiro[3], Edmar Zanoteli[3]

[1]Instituto Neurolum, São Paulo SP, Brazil.
[2]Universidade Estadual de Campinas, Campinas SP, Brazil.
[3]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Clara Gontijo Camelo; Email: claragc@gmail.com.

Case presentation: A boy, the first child of non-consanguineous parents, had an uneventful pregnancy and delivery, reaching developmental milestones on time. He showed elevated liver enzymes, prompting further investigation that revealed a CPK level of 19,700U/L. During a pediatric neurology evaluation, he exhibited difficulty running, an inability to jump, and required assistance to climb stairs. Further investigation identified a duplication of exon 2 in the Duchenne muscular dystrophy (DMD) gene. He was diagnosed with DMD at 4 years and 11 months old and began corticosteroid therapy at 5 years old (prednisolone 0.75mg/kg/day, daily use). An anti-AAVrh74 antibody test was below the reference value, and the patient received gene therapy with Microdystrophin (Elevidys) at 5 years and 8 months old. The medication infusion lasted 1 hour and 30 minutes and was uneventful. Per the infusion protocol, the prednisolone dose was increased to 1.75mg/kg/day (an increase of 1mg/kg/day) one day before the infusion and will be maintained at this dose for at least 60 days post-infusion. For five days post-infusion, the patient experienced nausea and vomiting, which were manageable with medication. There were no reports of fever or fatigue. One week post-infusion, the patient showed no abnormal laboratory results (platelets, liver function, or troponin-I). **Discussion:** This was the first DMD patient receiving gene therapy in Brazil. In June 2023, the FDA approved Microdystrophin therapy

(Elevidys) under accelerated approval for ambulatory boys aged 4-5 years with DMD, provided they do not have variants affecting exons 8-9. The therapy involves a single dose, and post-infusion monitoring is required for at least three months, including weekly liver function tests and clinical exams for three months, weekly blood counts for one month, and weekly troponin-I levels for one month, with more frequent monitoring as needed. Clinical studies suggest that patients receiving this medication show disease stabilization with maintenance of time to rise. However, studies have yet to show positive results for the primary outcome of the North Star Ambulatory Assessment. The most serious side effects reported to date include immune-mediated myositis and myocarditis. Common side effects, though not severe, include nausea, vomiting, fever, and malaise. **Final comments:** A new era of treatment for patients with DMD has begun, highlighting the need to understand the long-term efficacy and safety of this medication.

Gene therapy for spinal muscular atrophy amid the dengue outbreak in Brazil: a case report

Felipe Franco da Graça[1], Marcondes Cavalcante França Jr.[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Felipe Franco da Graça; Email: felipefgraca@hotmail.com.

Dengue fever is a mosquito-borne viral disease prevalent in tropical and subtropical regions globally, primarily spread by the Aedes aegypti mosquito. It manifests in a spectrum from mild flu-like symptoms to severe, life-threatening conditions. Among the classic laboratory manifestations, we observe thrombocytopenia and alterations in liver enzymes, which are mostly asymptomatic but can potentially evolve into more severe conditions. Given that these same laboratory changes can also be observed following therapy with onasemnogene abeparvovec (OA) for spinal muscular atrophy (SMA), the occurrence of dengue in patients after infusion may lead to potential complications. We describe the case of a patient with SMA Type I, diagnosed at 6 months of age (with 2 SMN2 copies) due to severe respiratory complications from an infectious episode. After diagnosis, the patient began treatment with Risdiplam with good response until the age of 9 months when gene therapy was infused. The patient was put into prednisolone at a dose of 1mg/kg for one month. Only mild thrombocytopenia (120,000/mm^3) and an elevation in transaminases less than 2 times the upper limit of normal were observed. One month after OA infusion, as per protocol, a gradual reduction of corticosteroid therapy was started, and by the eighth week post-infusion, the patient was on a 0.25mg/kg dose of prednisolone. At this point, the patient began to exhibit symptoms of fever, lethargy, red spots on skin, thrombocytopenia of 80,000/mm^3 and transaminase levels elevated to three times the upper limit of normality. Considering the concurrent dengue outbreak in Brazil at the time, serology was ordered and turned out to be positive. Since there were no similar cases described in the literature, we decided to keep prednisolone dose, and to recollect samples every 2 to 3 days. Eight days after the onset of symptoms, there was an improvement in laboratory findings with normalization of all values. Thereafter we decided to discontinue corticosteroid therapy.

General evaluation of drugs used by post-stroke patients in the city of Marabá/Pará

Francielly de Fátima Araújo da Silva[1], Adalberto Alves Moreira Neto[1], Maria Joana da Silva Pinto[2], Thawanny Gomes Varão[1], Ruth Carvalho Machado de Mendonça[1], Samuel Nunes Silva[1], Alexia Adriane Santiago Abdon[1], Vinicius Dirlan Rodrigues Pinto[1], Jorge Luiz Dutra Junior[1], Alexsandro Julio Rodrigues da Silva Júnior[1]

[1]Universidade do Estado do Pará, Marabá PA, Brazil. [2]Universidade Federal do Pará, Belém PA, Brazil.

Correspondence: Francielly de Fátima Araújo da Silva; Email: franciellyamrr@gmail.com.

Background: A stroke is defined as an abrupt interruption of blood flow to the brain parenchyma, causing significant neurological deficits in the affected region, lasting more than 24 hours. Physiological mechanisms classify it as ischemic (iS) and hemorrhagic (hS) and its main risk factors, also called disease-modifying factors, are comorbidities such as high blood pressure, diabetes mellitus, cardiovascular arrhythmias, dyslipidemia, smoking, alcoholism and obesity. In Brazil, the medication list available for stroke's treatment is based on the classes of non-steroidal anti-inflammatory drugs, antihypertensives, antithrombotics and thrombolytics. **Objective:** Outline the main classes of medication used after a stroke episode by patients treated at a healthcare unit in the state of Pará, Brazil. **Methods:** This is a cross-sectional, unicentric study with quantitative criteria, with a sample of 20 patients with cerebrovascular disease (α=0.05), selected after a routine consultation at the neurology outpatient clinic at the São Padre Pio dos Capuchinhos Healthcare unit, in the city of Marabá, in the State of Pará. The data acquisition took place in October and November of 2023, using a general clinical-epidemiological assessment instrument created by the authors, which questioned the medications used by patients. **Results:** In total, 46 different drugs were found based on the responses of the 20 patients in the sample, with 1 being the minimum amount of medications taken daily by a patient and 8 concomitant medications being the maximum amount. Antihypertensives were the medications most frequently taken by patients (rf=0.40), followed by hypoglycemic drugs (rf=0.14), non-steroidal anti-inflammatory drugs (rf=0.12) and anticonvulsants (rf=0.06). The presence of anti-vertigo medications such as betahistine dihydrochloride in the routine of these patients got our attention (rf=0.03). These results are related to the risk factors for stroke, especially the high number of antihypertensive drugs, in addition to the fact that the registered medications demonstrated the presence of polycomorbidities that accompanied cerebrovascular accident (CVA) episodes, such as inflammatory diseases, Alzheimer's disease, Parkinson's and diseases that affect the vestibular system, such as Ménière's disease (endolymphatic hydrops). **Conclusion:** In the panorama of the studied population, the use of post-stroke medications was associated with risk factors and polycomorbidities. The highest use of antihypertensive drugs was highlighted, followed by hypoglycemic drugs, NSAID's and anticonvulsants.

Background: The state of Amazonas, located in the northern region of Brazil, exhibits a demographic profile characterized by indigenous and African influence alongside European admixture. Historically, the region has attracted migrants from various parts of Brazil, mainly from Pará (north of Brazil) and northeastern states. These migrations, driven by economic opportunities and social factors, have led to a complex intermingling of genetic backgrounds within the Amazonian population. **Objective:** In this study, we investigate the influence of internal migration within Brazil on the prevalence of Huntington's disease in the state of Amazonas. **Methods:** We studied 22 families affected by HD in the state of Amazonas and identified a total of 51 genetically confirmed cases. We trace the origin of the oldest affected member of each family, within Brazil or abroad. We analized the genetic characteristics of families according to their geographic origin. **Results:** We identified 22 patients (43.1%) originated from families with roots in northeastern states. Another 22 cases (43.1%) were from the North of Brazil, 1 (1.9%) patient from Venezuela and 6 patients (11.7%) of unknown origin. The paternal transmission is predominant among patients from the Amazonas state, with 8 out of 13 cases exhibiting this mode of inheritance. Similarly, patients from Ceará show a higher prevalence of paternal transmission, with 10 out of 15 cases following this pattern. The other states display a more balanced distribution between paternal and maternal transmission. Regarding the size of CAG expansions, patients from the Amazonas state exhibit the largest average expansion size at 50.9 repeats, followed by patients from Pará (47.6 repeats), Ceará (46.4 repeats), and Pernambuco (46.2 repeats). **Conclusion:** This study highlights the impact of internal migration on the distribution of Huntington's disease within Brazil with a significant contribution from other states to the prevalence of Huntington's disease in Amazonas. The influx of migrants from northeastern states, where HD prevalence may be higher due to genetic and environmental factors, has likely contributed to the increased occurrence of the disease in Amazonas. This underscores the importance of considering local demographic factors and historical migration patterns in understanding disease epidemiology.

Background: The identification of the Huntington's disease (HD) gene was a major historical milestone that enhanced understanding of the pathology and paved the way for future therapeutic approaches. **Objective:** Celebrating the last three decades since this event, the aim of this study is to revisit the techniques that led to the discovery of the HD gene. **Methods:** This is a review using the PubMed, Web of Science, LILACS, Embase, and SciELO databases, with the search terms "Huntington Disease", "Genetic Markers", "Chromosome Mapping" and "Genetic Linkage" combined with boolean operators. **Results:** In 1979, prominent geneticists gathered with the aim of exploring the potential of Restriction Fragment Length Polymorphism (RFLP) technology, which had recently been described, to map the location of the HD gene. It was essential to evaluate large families, as genetic linkage required observing multiple transmissions within the family to determine the proximity of the markers on the chromosomes. The main method to identify the HD gene was positional cloning via linkage analysis, mapping genes based on their co-segregation with specific genetic markers. Using linkage analysis, researchers mapped the HD gene to chromosome 4, observing marker co-inheritance with the disease in large families. Researchers used linkage analysis with extensive HD family pedigrees and a limited set of polymorphic markers detected via Southern blot. The G8 probe showed a distinctive RFLP pattern linked to HD in two large affected families. They identified HindIII palindromic sites (H1 and H2) within the chromosomal region using this probe. Fragment lengths varied among different HD lineages. Despite identifying G8's proximity to the HD gene, they used human-mouse somatic cell hybrids to determine its specific human chromosome origin. By performing Southern blot with the G8 probe and chromosomal DNA from hybrids, they identified cell lines with human DNA homologous to G8. This mapped the G8 probe to a specific human chromosome, as they knew the chromosomal composition of each cell line. They concluded the G8 probe only hybridized with DNA from human chromosome 4. Consequently, in 1983, they concluded that the G8 DNA probe was located on human chromosome 4 and inferred that the HD gene resided in the region corresponding to the G8 DNA probe. **Conclusion:** The main techniques that enabled the discovery of the HD gene were RFLP, positional cloning, linkage analysis, and hybridization of human and mouse somatic cells. These techniques allowed for the identification of the HD gene, driving studies and publications on the disease. Now, we understand HD is autosomal dominant with CAG expansion in HTT gene on chromosome 4p16.3. Although disease-modifying treatment is still emerging, the search for the HD gene has illuminated the scientific community and introduced technologies used in other diseases. Today, genetic therapies are a closer possibility, inspiring future generations of researchers.

Genetic testing in patients with oligo: or asymptomatic elevated CK

Ana Luisa de Carvalho Cardozo Hernández[1], Weverton Carlos da Silva Teixeira[1], Andre Macedo Serafim da Silva[1], Edmar Zanoteli[1], Cristiane de Araújo Martins Moreno[1], Lucas Marenga de Arruda Buarque[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Ana Luisa de Carvalho Cardozo Hernández; Email: ana_luisa_1997@hotmail.com.

Background: Elevated creatine kinase (CK) levels are the most sensitive indicator of muscle injury. An increased serum level of CK in pauci- or asymptomatic individuals is a diagnostic challenge, as it may be associated with either physiological conditions, such as exercise, or even signal an ominous neuromuscular disease. **Objective:** To assess the percentage of patients diagnosed with a neuromuscular disorder in the setting of elevated CK with an oligo- or asymptomatic presentation within a specialized neuromuscular service. **Methods:** Retrospective transversal study performed in the outpatient clinic of neuromuscular disorders from HCFMUSP. Medical records from all patients who underwent genetic testing in our Neuromuscular Clinic from the period of 2015-2023 were obtained and the inclusion criteria were (1) CK dosage equal to or higher than 5 times the upper limit reference value and (2) asymptomatic or oligosymptomatic patients, with clinical complaints compatible with the hypothesis of a metabolic disorder (we searched for the words myalgia, fatigue, mild weakness' without objective clinical muscle weakness - and/or history of rhabdomyolysis). Exclusion criteria: Occasional causes of elevated CK, such as malignancies, drug and alcohol abuse, rheumatic, thyroid, and parathyroid disorders, infections, hematologic diseases, or use of drugs such as statin. **Results:** 34 out of 724 patients were selected. 23 patients were male and 11 female, the mean age at onset was 24 years, and the mean disease duration was 9 years. Mean serum CK was 2692, and levels varied between 978 to 3x106 (Reference value <192). 26 (76.4%) patients had no family history of neuromuscular disorders. 22 (75.9 %) patients complained of myalgia, 20 (69%) had fatigue, 16 (55.1%) complained of some degree of muscle weakness and 5 (17.2%) were asymptomatic. In additional exams, 4 (26.7%) patients presented with a myogenic pattern on EMG, 7 (53.8%) presented with myopathic changes in MRI, and 13 (56.5%) had alterations in muscle biopsy. 31 patients were tested with a genetic panel for metabolic muscle disorders (12 from INVITAE and 19 from Mendelics), and 3 individuals underwent full exome analysis. Genetic testing revealed pathological variants in 11 patients, variants of unknown significance in 13 individuals, and the absence of variants in 7 subjects. The most frequent mutated genes were ETFDH (n=3), followed by ANO5 (n=2) and GAA (n=2). Other mutated genes included B4GALT1 (n=1), CAP3 (n=1), PYGM (n=1), and RYR1 (n=1). **Conclusion:** Genetic testing in oligo- or asymptomatic patients with elevated CPK was associated with pathological variants in about a third of patients. ETFDH, ANO5, and GAA were the most common mutated genes found. This highlights the importance of this finding in metabolic disorders and certain forms of myopathy.

Genotype/phenotype correlation and peripheral neuropathy in Wilson's disease (WD) in the state of Ceará, Brazil

Caio Levi Mendes Costa[1], Jéssica Queiroz de Sousa Sobrinho[1], Francisco de Assis Aquino Gondim[1], Alan Duarte Braz[1], Leonardo José Rodrigues de Araújo Melo[1], Francisco Duque de Paiva Giudice Junior[1], Leonardo Elias Araujo dos Santos[1], Mariana Alcântara Tavares[1], Rodrigo Fagundes da Rosa[1], Emanuela Freire Caetano Davi[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Caio Levi Mendes Costa; Email: caiogrebr@gmail.com.

Background: Wilson's disease (WD) is a rare autosomal recessive disorder caused by mutations in the ATP7B gene located on chromosome 13, affecting copper metabolism. Patients may be homozygous for a single mutation or compound heterozygous with two different mutations. More than 700 pathogenic variants of the ATP7B gene have been identified, and most WD patients exhibit compound heterozygosity. We have previously reported small fiber neuropathy in 4 patients with WD (Gondim et al. 2014). **Objective:** To analyze the ATP7B mutations and evidence of neuromuscular involvement (especially neuropathy) in patients followed up at Universidade Federal do Ceará. **Methods:** This summary describes the genetic test results of 13 patients of both sexes with WD, evaluated for neuromuscular complications at the Neurology Service of the Walter Cantídio University Hospital – Fortaleza/CE (CAAE: 05954818.9.0000.5045). Almost all (n = 12) of the patients were part of the cohort from Sobrinho, MSc dissertation, 2021 (n = 14). **Results:** Thirteen patients were analyzed, 7 men and 6 women, with an average age of 44 (30 to 58 years). Of these, 6 (46.15%) are homozygous, and 7 (53.85%) are compound heterozygous. Of the homozygous patients, 4 out of 6 (66.67%) have point mutations, and 2 (33.33%) have deletions. Both deletions correspond to the c.3402del (p.Ala1135Glnfs*13) mutation. Among the point mutations, there are 2 (33.33%) cases of c.2123T>C (p.Leu708Pro), 1 (16.67%) case of c.3809A>G (p.Asn1270Ser), and 1 (16.67%) case of c.1708-1G>A. Of the compound heterozygous WD patients, 2 out of 7 (28.57%) have combinations of Point Mutation + Deletion: c.3517G>A (p.Glu1173Lys) + c.3402del (p.Ala1135Glnfs13) and c.1708-1G>A + c.3402del (p.Ala1135Glnfs13). One patient (14.29%) has the combination Deletion + Point Mutation: c.3402del (p.Ala1135Glnfs13) + c.1934T>G (p.Met645Arg). There is 1 (14.29%) case of Point Mutation + Splice Donor: c.3517G>A (p.Glu1173Lys) + c.1543+1G>C, and 1 (14.29%) case of Intronic + Splice Donor: c.3061-12T>A + c.1543+1G>C. There is 1 (14.29%) case of Duplication + Point Mutation: c.2304dup (p.Met769Hisfs26) + c.3772A>T (p.Lys1258Ter), and 1 (14.29%) case of Point Mutation + Point Mutation: c.3694A>C (p.Thr1232Pro) + c.3061-12T>A. The most frequent allelic mutation was the deletion c.3402del (p.Ala1135Glnfs*13), present in 7 alleles (29.92%). Related to the neuromuscular changes in Sobrinho (2021), 8 (57%) patients had peripheral small fiber neuropathy, identified by skin wrinkling test, and 2 (14%) had involvement of large fibers: one with axonal sensorimotor polyneuropathy and myopathy; the other exhibiting loss of ankle jerks and carpal tunnel syndrome. **Conclusion:** The genetic alterations of the 13 WD patients reinforces the wide variety of possible mutations in the disease and the high heterogeneity of mutations in the Brazilian population due to diverse ethnic backgrounds. Neuromuscular involvement is common in WD patients.

https://doi.org/10.5327/CBN240834

Genotype-phenotype correlations of FGFR2/3 variations: beyond craniosynostosis - a systematic review

Gisele Lucia Canto Gomes[1], Vinicius Bacelar Ferreira[1], Bruno Machado da Silva[1], David Abraham Batista da Hora[1], Patrícia Ferreira Borges Peixoto[1], Paulo Victor Zattar Ribeiro[2]

[1]Universidade Federal do Amazonas, Manaus AM, Brazil.
[2]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Gisele Lúcia Canto Gomes; Email: glc.canto@gmail.com.

Background: The FGFR genes provide instructions for the construction of a protein called fibroblast growth factor receptor. Variations of FGFR2 gene are commonly linked to syndromes causing craniosynostosis and FGFR3 is generally related to achondroplasiahypochondroplasia. However, various conditions have been linked to pathogenic variants within that gene group. Understanding genotype-phenotype correlations can contribute to more accurate diagnoses, enabling personalized treatments and genetic counseling strategies. **Objective:** To explore and synthesize the genotype-phenotype correlations of FGFR 2 and 3 gene variations in addition to craniosynostosis, to provide a more comprehensive understanding of their clinical and biological impact. **Methods:** A systematic review was conducted according to PRISMA guidelines. PubMed, Embase, Web of Science and Cochrane Central databases were searched for studies. The words used for research were: "FGFR 3 variants", "FGFR2 variants", "phenotype", "clinical features" and "manifestations". All studies that cited variations in FGFR 2 and 3 genes and phenotypes were included regardless of the study design. Animal models, in vitro studies, and reviews were excluded. **Results:** Nine studies were included, three of

which referred to cases of craniosynostosis phenotype associated with FGFR2/3 mutations. Celie et al. associated the c.1024T>A;p.C342 S variation in FGFR2 with Jackson-Weiss Syndrome. Kant et al. associated the p.M5281 and p.F384L variations with short stature. . Paur et al. associated FGFR3 with hepatocellular carcinoma and Sturla et al. reported FGFR3 variations with neuroblastoma, Ewing's sarcoma, neurofibrosarcoma, rhabdomyosarcoma, bladder carcinoma, melanoma, prostate carcinoma, colorectal carcinoma, breast cancer and myeloma. And Wang et al. reported two cases of c.1024T>C, p.Cys342Arg variations in FGFR2 associated with Crouzon syndrome. **Conclusion:** FGFR are critical for various developmental processes, and pathogenics variations in FGFR2, and FGFR3 genes are well-documented for their role in craniosynostosis syndromes. However, nowadays, evidence has been suggesting the influence in a broad spectrum of clinical phenotypes, such as Jackson-Weiss syndrome and neoplasia. These insights underline the importance of comprehensive genetic testing and tailored clinical management for individuals with FGFR gene variations, extending beyond the conventional focus on craniosynostosis. Future research should further explore these genotype-phenotype relationships in order to achieve these therapeutic goals.

https://doi.org/10.5327/CBN240835

Gerstmann syndrome as a rare presentation of cerebral venous thrombosis

Guilherme Antonio Silva Ribeiro[1], Sofia Mônaco Gama[1], Eva Carolina Andrade Rocha[1], João Vitor Gerdulli Tamanini[1], Luccas Almeida Andrade[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Guilherme Antonio Silva Ribeiro; Email: guiribeiro1018@gmail.com.

Case presentation: A 36 year old woman presented to the emergency department with a thunderclap headache that started one day before. She also complained of blurred vision and denied fever, seizures or focal deficits. The past medical history was notable for tobacco smoking and she was not taking anticoagulants. Physical exam was remarkable for severe arterial hypertension (245x126 mmHg), papilledema and right homonymous hemianopsia. The patient also had left-right confusion, finger agnosia, dyscalculia and dysgraphia. Laboratory tests and cerebrospinal fluid analysis were normal. Brain computerized tomography (CT) and venogram revealed a left parieto-occipital lobar hemorrhage (volume: 57mL, ICH score 1) and thrombosis of the superior sagittal sinus, respectively. The diagnosis of intracerebral hemorrhage secondary to cerebral venous thrombosis was made. Intravenous anticoagulation was initiated, resulting in a complete resolution of the headache within 5 days. **Discussion:** In 1924, the neuroscientist Josef Gerstmann first described the Gerstmann syndrome (GS), which is characterized by a tetrad of symptoms: left-right confusion, dysgraphia, dyscalculia and finger agnosia . This condition likely results from disconnection of the parietal subcortical white matter due to injury of the left angular gyrus (parietal lobe) and adjacent structures. GS is a rare neurological condition, with no clear epidemiology. The most common etiology is ischemic stroke of the left parietal lobe due to occlusion of the left posterior cerebral artery. It can also be secondary to trauma, neoplasms, degenerative diseases, vascular malformations, infections and other less common etiologies. This case describes a rare presentation of GS due to intracerebral hemorrhage secondary to superior sagittal sinus thrombosis. **Final comments:** GS is characterized by left-right disorientation, acalculia, finger agnosia and agraphia. Usually, this condition is caused by ischemic stroke, trauma, neoplasms, degenerative diseases, vascular malformations and infections GS can be a rare presentation of intracerebral hemorrhage secondary to superior sagittal sinus thrombosis

https://doi.org/10.5327/CBN240836

Giant axonal neuropathy: case report of an intermediate form with late manifestations

Amanda Leme da Silva Campinas[1], Lucas Do Rego Barros Correa Martins[1], Laura Alonso Matheus Montouro[1], Maria da Penha Ananias Morita[1], Érica Nogueira Coelho[1], Eduardo de Paula Estephan[1]

[1]Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto SP, Brazil.

Correspondence: Amanda Leme da Silva Campinas; Email: amandalsc12@hotmail.com.

GAN-related neurodegeneration (GAN-RD) comprises a phenotypic spectrum ranging from severe to milder pure early-onset sensorimotor neuropathies Oversized axons are the pathological hallmark of the disease. In this case report we depicted a GAN-RD with intermediate phenotype, illustrating tardy manifestations of this ultra-rare condition. **Case presentation:** A Brazilian female, with no familial history of neurological disorders, born to non-consanguineous parents, started with difficulty to jump, to run and to keep slippers on feet (due to weakness on toes), at the age of 3. At 6-years-old, weakness progressed and bilateral foot drop was present. At 15-year-old upper limbs were affected, with weakness and atrophy. At 22, a wheelchair was needed to move for long distance, and at 34 patient were restricted to wheelchair and with urinary incontinence. Nocturnal ventilatory assistance, was initiated at age of 42. At the last attendance, with 43 years, she presented with areflexic paraplegia and predominantly distal upper limbs weakness, with intense atrophy on feet and hands. Were also noted: appendicular ataxia, dysphagia, dysarthria, facial weakness, hypoesthesia and impaired vibration sensibility on 4 limbs, more intense distally. Neither curly/kinky hair nor intellectual disability were present. Electrophysiology revealed severe diffuse sensory-motor neuropathy with axonal predominance. Brain magnetic resonance imaging (MRI) showed, cerebellar atrophy and bilateral and symmetrical hyperintense lesions on T2-weighted sequences compromising the middle cerebellar peduncles and brainstem in medulla region. On New Generation Sequencing panel for neuropathies biallelic variants were seen on GAN gene two variants in heterozygosity: Chr16:81.388.038AGTT>A (pVal106del ENST00000648994 - c.315_317delGTT - ENST00000648994) and Chr16:81.388.010 A>C (p.Ile95Leu ENST00000648994 - c.283A>C - ENST00000648994). **Discussion:** Giant axonal neuropathy is an inherited autosomal recessive neurodegenerative disease that affects both central and peripheral nervous systems. For differential diagnosis must be considered Charcot-Marie-Tooth (CMT) hereditary neuropathy, especially for intermediate and mild GAN-phenotypes. Other diagnosis to differentiate from include classic infantile neuroaxonal dystrophy and leukodystrophies. There is no genotype-phenotype correlation for GAN-RD, and family members with the same pathogenic variant can present different clinical phenotypes. Actually, our case had been followed as a hereditary neuropathy until the possibility of genetic test. The severity, and the presence of cerebellar ataxia were red flags against CMT hypothesis. Moreover, in the last years, she began to have cranial nerve involvement, which is also uncommon for most hereditary neuropathies. **Final comments:** This case report brings attention to this ultra-rare disease, illustrating a late clinical picture of an intermediate form of GAN-RD.

Girdle muscular dystrophy, severe LGMD 2F subtype in a pediatric patient: case report

Cláudio de Souza Fernandes Júnior[1], Cláudio de Souza Fernandes[1], Matheus Araújo de Medeiros[2], Lucas Medeiros Dunga[2], Lucca Ferdinando Queiroz Fernandes[2], Artur Rebouças de Souza[2], Maria Eduarda Medeiros Martins[2], Diógenes Emanuel Dantas da Silva[2], Tereza Cristina Batista Dias[2], Iury Hélder Santos Dantas[2]

[1]Universidade Estadual do Rio Grande do Norte, Caicó RN, Brazil.
[2]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.

Correspondence: Cláudio de Souza Fernandes Júnior; Email: claudio.junior.711@ufrn.edu.br.

Case presentation: A 12-year-old male patient developed progressive muscle weakness of the pelvic and scapular girdle in a short period of time during early childhood, with significant involvement of the lower limbs, compromising walking and sitting. The progression of the disease began at the age of 6, with proximal and symmetrical weakness of the hip muscles. At the age of 8, the patient's pelvic girdle was affected, with a significant loss of strength in both upper limbs. In addition, fractures in the right upper limb caused by low-energy trauma demonstrate a significant correlation between the development of dystrophy and bone fragility. The condition evolved into weakness of the breathing muscles which culminated in obstructive sleep apnea (OSA), especially in the REM phase, due to hyper-relaxation of the pharyngeal muscles. The clinical suspicion was muscular dystrophy of the waist, characterized as delta-sarcoglycanopathy. A genetic evaluation confirmed the diagnosis of LGMD 2F, with a homozygous pathogenic variant in the SGCD gene. In addition, he was diagnosed with severe gastroesophageal reflux, with daily episodes of vomiting and regurgitation, requiring maximum doses of prokinetics and control medications. The condition reinforces the picture of intestinal hypomotility due to the inability to walk. In 2024, the patient had a BMI of 14.3 (below the 3rd percentile), maintaining inadequate nutrition due to dyspepsia and gastroparesis. Intake is limited to 150 ml per meal, insufficient to meet nutritional needs, resulting in a loss of 3.85 kg between February and May (13.3% of previous body weight). A diet was proposed and he was referred to physiotherapy and speech therapy. **Discussion:** Girdle muscular dystrophy type 2F is a rare form of muscular dystrophy, characterized by progressive weakness of skeletal muscles, predominantly of the scapular and pelvic girdles. The SGCD gene is implicated in this condition, with homozygous pathogenic variants frequent in some populations, including Brazilian families. The case highlights the complexity and severity of LGMD 2F, with rapid progression leading to a significant loss of function and mobility. Management of the disease is multidisciplinary, involving physiotherapy to maintain muscle function, nutritional support to combat malnutrition and dyspepsia, as well as respiratory care to prevent complications associated with obstructive sleep apnea. Bone fragility increases the risk of fractures, requiring constant vigilance and interventions to prevent new injuries. **Final comments:** Severe LGMD 2F subtype girdle muscular dystrophy is rare, especially with progression in such a short time. Several factors contribute to the severity of the disease, especially additional comorbidities. The multidisciplinary team plays a decisive role in the evolution and outcome of the condition.

Globus pallidus internus deep brain stimulation for severe Tourette's syndrome: a case report

Rodrigo Fernandes Nitsch[1], Patrícia Áurea Andreucci Martins Bonilha[1], Mariana de Oliveira Trintinalha[1], Nathalia Cabral Bergamasco Torato[1], Mateus Coltro Dornelles[1], Leonardo Almeida Frizon[1], Alexandre Novicki Francisco[1], Marina Farah[1]

[1]Pontifícia Universidade Católica do Paraná, Hospital Universitário Cajuru, Curitiba PR, Brazil.

Correspondence: Mateus Coltro Dornelles; Email: mateuscdornelles@gmail.com.

Case presentation: G.D.N 30 years old, female was referred by her psychiatrist to a specialized deep brain stimulation (DBS) clinic due to a lifelong severe and refractory Guilles de La Tourrete Syndrome. Symptoms began at the age of 5 and slowly progressed with important vocal and motor tics associated with aggressiveness, coprolalia and aggression both self-inflicted and towards others. Pharmacological treatment, at time of presentation was Clozapine 100mg bd, |Risperidone 1mg bd, Fluoxetine 20mg bd, Biperiden 2 mg bd, Levomepromazine 5 drops at night. The patient was referred for a DBS approach. Initial Yale Global Tics Severity Scale (YGTSS) was 86 and both DBS devices were gradually adjusted (initially every 2 weeks; later, every 3 months) with significant clinical improvement: motor tics and aggressiveness lessened (current YGTSS after 1 year: 63), and both the patient and her mother referred gains in independence and life quality, after one year of DBS. **Discussion:** Tourette syndrome is a rare psychiatric disorder with estimated prevalence of approximately 0.66% of school age children with only a small fraction of those cases lasting until adulthood with debilitating symptoms. Tics brief movements or sounds that resemble voluntary actions, but appear suddenly, without regularity, often exaggerated in intensity and are repetitive and inopportune to social context.- (more than 1 motor and 1 vocal) beginning before 18 years of age and lasting for over a year define the syndrome. Even though the pathophysiology involving these symptoms is not completely identified, functional neuroimaging studies have already brought light upon the involvement of important structures from the dopaminergic inhibitory circuit (such as the basal ganglia), the motor cortex and complex cortico-cortical neural networks. Managing these cases demands a multidisciplinary approach and often turns out to be a challenging task. The development of new treatment strategies, especially regarding severe and pharmacologically resistant cases - such as the one presented above -, is a necessity and DBS poses as a viable, potentially effective, and relatively safe invasive option. **Final comments:** We present a case of an adult patient struggling with severe Tourette syndrome, impairing daily life activities, with life long pharmacological resistance, who presented significant improvement following bilateral GPi DBS implantation - a novel approach for a rare debilitating disease.

Glossopharyngeal neuralgia secondary to bone fibrodisplasia: a case report

Ahmad Kassem El Zein[1], Rogério Tuma[1], Mauricio Silva Teixeira[1], Paula Fiuza Rodrigues de Medeiros Lacerda[1], Lucas Henrique de Moura Rogerio Garcia[1], Matheus Rodrigues Nogueira[1], Joana Laura Aihara Barbosa[1], Josenice Gomes Trindade Seidel[1], Julia Martins Brunelli[1], Lucas D'Andrea Pereira Sousa[1]

[1]Hospital Sírio-Libanês, São Paulo SP, Brazil.

Correspondence: Ahmad Kassem El Zein; Email: ahd-95@hotmail.com.

Case presentation: A 38-year-old previously healthy woman presented with multiple episodes of sharp pain on the right side of her face and ear, radiating to her jaw and malar region, each episode lasting about a minute. The pain, described as stabbing, improved with cold stimuli. She reported increased discomfort while chewing and swallowing but denied fever or other symptoms. Despite heightened sensitivity on the right side while chewing, she did not identify other triggers. A neurological examination revealed no deficits. She was hospitalized for further investigation and better pain management, receiving intravenous phenytoin empirically due to the neuropathic nature of her pain.Laboratory evaluations, including metabolic, rheumatologic, and hematologic tests, showed no abnormalities. Magnetic resonance imaging (MRI) of the temporal and cranial bones with arterial studies revealed T2/FLAIR hyperintensity and post-contrast enhancement, suggesting a fibro-osseous developmental condition in the right temporo-occipital region, compressing the jugular foramen. These findings supported a diagnosis of glossopharyngeal neuralgia secondary to jugular foramen compression caused by osteofibrous dysplasia. She was initially treated with carbamazepine, 200mg twice daily, gradually increasing to 800mg/day, and pregabalin, 75mg once daily, which provided satisfactory pain control. Rhizotomy was considered if pharmacological therapy failed. **Discussion:** Glossopharyngeal neuralgia is a rare condition characterized by shock-like pain in the jaw and face, often triggered by coughing or swallowing. In rare cases, it can lead to cardiovascular issues due to involvement of the vagus nerve. Classic glossopharyngeal neuralgia is typically caused by vascular contact, often from the posterior inferior cerebellar artery, while secondary forms result from structural changes such as fibromuscular dysplasia or tumors. Differential diagnoses, including oral cavity tumors and trigeminal neuralgia, must be ruled out when an idiopathic condition is suspected. Diagnosis relies on patient history, clinical examination, and MRI of the temporal and cranial bones.For treatment, carbamazepine is often used at a starting dose of 200 mg twice daily, potentially increasing to 1200 mg if tolerated. In refractory cases, additional medications and surgical options like rhizotomy or Stereotactic Radiosurgery (SRS) may provide better pain control. **Final comments:** This case study highlights a rare instance of glossopharyngeal neuralgia where the clinical presentation could easily be confused with other conditions. Imaging is crucial for accurate diagnosis.

Glossopharyngeal neuralgia: a case report

Bibiana Mayer[1], Chadi Emil Adamo[2]

[1]Universidade de Ribeirão Preto, Ribeirão Preto SP, Brazil.
[2]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Chadi Emil Adamo; Email: neurochadi@outlook.com.

A.P.T, woman, 27 years old. At the age of 13, she experienced pain in the lower region of the right hemiface. This complaint was concentrated in the masseter and pre-auricular region, radiating to the angle of the jaw, with paroxysmal (multiple pulsating) quality, and a duration of approximately 1 minute and ocurred several times in a day. There was also burning pain in the right half of the tongue. The pain was aggravated by touch, swallowing, washing her face, laughing, and brushing her teeth. A few weeks ago, she underwent a dental procedure and experienced a significant exacerbation of the condition, making her unable to work. In this context, she underwent treatment with medications such as codeine, tramadol, and morphine infusions, but with disappointing results. During a neurological consultation, a diagnosis of trigeminal neuralgia was suggested with red flags for other diagnoses (age <50 years and pain in the hemilanguage) and glossopharyngeal neuralgia due to the topography of her pain. Therefore, a cranial MRI with FIESTA sequence was requested. This showed an extra-axial formation with intensity equal to cerebrospinal fluid posterior to the emergence of the IX, X, and XI cranial nerves on the right, with slight anterior displacement of these nerves, measuring approximately 1.9x0.9x0.7 cm at its largest diameters. The trigeminal pathway was intact. This image was compatible with a probable arachnoid cyst with slight anterior compression of the emergence of the IX cranial nerve on the right. In this context, a diagnosis of glossopharyngeal neuralgia was made, and treatment with carbamazepine was started, with a dose progression up to 800mg/day. The patient achieved complete remission later with the combination of low-dose lamotrigine (100mg/day). She is currently undergoing pharmacological management, and the surgical option for arachnoid cyst removal will be considered in case of refractory response. Glossopharyngeal neuralgia is a severe transient stabbing pain experienced in the ear, base of the tongue, tonsillar fossa, or beneath the angle of the jaw. The pain is therefore felt in the distributions of the auricular and pharyngeal branches of the glossopharyngeal nerve. It is commonly provoked by swallowing, talking, or coughing and may remit and relapse in the fashion of TN. Stimulation of the vagus can result in syncope. In most cases, this condition is idiopathic, but some instances might be due to symptomatic causes, again compression of the nerve by tumours, in this case, an arachnoid cyst. Patients will suffer from episodes of pain lasting for weeks or months, and then have periods of remission.

Glossopharyngeal neuralgia: case report

Marco Antonnio dos Santos Rocha[1], Leticia Suppi de Oliveira[1], Roberta Derossi de Souza[1], Maiara Leticia Geiss[1]

[1]Universidade do Planalto Catarinense, Lages SC, Brazil.

Correspondence: Leticia Suppi de Oliveira; Email: suppilele@gmail.com.

Case presentation: A 75-year-old female presented to the emergency department of a major hospital situated in the Serra Catarinense region with left-sided cervicalgia radiating to the jaw, tongue, palate and left auricular region, dizziness and lipothymia. Her symptoms started abruptly the day before, were severe recurrent and associated with talking and swallowing. Her neurological exam was unremarkable, with the exception of an absent gag reflex bilaterally. Lidocaine spray application to the patient's posterior oropharynx resulted in localized paresthesia and symptom amelioration. A hypothesis of Glossopharyngeal Neuralgia (GN) was made. Past medical history included well-controlled arterial hypertension managed with Losartan and diffuse thyroid gland enlargement with a total volume of 22.62 cm^3, devoid of clinical consequences. Brain Magnetic Resonance Imaging and Magnetic Resonance Angiography confirmed a contact between the left posterior inferior cerebellar artery and glossopharyngeal nerve. This finding, with the whole clinical picture, confirmed the given hypothesis. She began on carbamazepine with dose increasing on the following days, as well as codeine for pain control and more applications of topical lidocaine. She was discharged with minor pain and no need for opioids and anesthetics. **Discussion:** GN clinically manifests as abrupt, intense unilateral pain episodes localized to sensory territories innervated by the glossopharyngeal nerve, including the mastoid bone, posterior pharynx, posterior third of the tongue, Eustachian tube, middle ear, oropharyngeal tonsils, and vocal folds, and may be accompanied by vagal symptoms. These episodes typically range from seconds to minutes and may occur multiple times daily, often triggered by head movements, coughing, speaking, sneezing, laughter, or mastication. The identification of concurrent diagnostic indicators is crucial for topographic diagnosis, which may also delineate etiological considerations. Notable diagnostic features include motor manifestations and the presence or absence of the gag reflex. Evaluation of swallowing and phonation functions involving the glossopharyngeal and vagus nerves is particularly pertinent in dysphagic and/or dysphonic patients. Accurate localization of compression is imperative for therapeutic stratagem. For patients without contraindications, contrast-enhanced MRI of the brain and soft tissues of the neck stands as the diagnostic modality of choice. Pharmacotherapy typically involves neuropathic agents that modulate action potentials and attenuate synaptic transmission, with Carbamazepine and Oxcarbazepine being foremost among them. In cases of refractory disease, stereotactic radiosurgery is a preferred minimally invasive alternative preceding consideration of neurovascular decompression surgery as a final resort. **Final comments:** GN constitutes a seldom-diagnosed entity that can be mistaken for other severe causes of head and cervical pain.

https://doi.org/10.5327/CBN240842

Glycemic imbalance, but not diabetes mellitus (DM), increases the risk of infection in patients with acute stroke admitted to a stroke unit: a cohort study in a reference hospital in Bahia

Gabriel Souza Medrado Nunes[1], Maria Eduarda Messias Vassoler[1], Milena Fernandes de Oliveira[1], Luiz Paulo Oliveira Martins[1], Gabriel Teles de Oliveira Piñeiro[1], Thaís Barbosa de Oliveira[1], João Pedro Fernandes Gonçalves[1], Pedro Antonio Pereira de Jesus[2] , Luana Araujo Passos[1], Gabriel Souza Suzart[1]

[1]Universidade Federal da Bahia, Salvador BA, Brazil. [2]Hospital Geral Roberto Santos, Salvador BA, Brazil.

Correspondence: Maria Eduarda Messias Vassoler; Email: maria.vassoler@ufba.br.

Background: Diabetes Mellitus (DM) is known to be associated with a higher risk of infection, particularly during hospitalization. However, the correlation between glycemic imbalance during hospitalization and infection rates in patients with and without DM is not well explored in many populations, including acute neurological patients. **Objective:** To understand the relationship between glycemic imbalance, diabetes, and the risk of infection during the hospitalization period in stroke patients at a stroke unit. **Methods:** This study enrolled patients with acute stroke admitted to a referral hospital's stroke unit in Bahia, between July/2023 and March/2024. Clinical and epidemiological characteristics were extracted from patients' medical records or obtained through personal interviews. Infection was defined as the administration of antibiotics or documented infection noted in medical records. The glycemic imbalance was defined by a hemoglucotest (HGT) reading exceeding 180mg/dL. The Mann-Whitney and Chi-Square tests were employed to examine associations. **Results:** The study included 213 patients, 51.2% of whom were female, with a median age of 66.3 years (IQR: 59-74.3). Regarding comorbidities, 36.2% had diabetes, 78.95% had hypertension, and 27.7% had dyslipidemia. Infection was diagnosed in 95 patients (44.6%). Among patients with diabetes, 54.4% had an infection, compared to 38.3% of the patients without diabetes, showing a significant risk of infection for diabetic patients ($p<0.05$) in the univariate analysis. Across all patients, 52.2% experienced at least one episode of glycemic imbalance (GI), with a median of 3 (IQR: 0-3) episodes. In general, more episodes of GI were associated with infection occurrence ($p<0.05$). Diabetic patients had an 83.1% frequency of GI, a median of 3 (IQR: 1-7) episodes, while non-diabetics had a 30.8% frequency and a median of 0 (IQR: 0-1) episodes. Subgroup analysis showed that the higher GI occurrence in diabetics was linked to a higher infection risk ($p<0.01$), but this was not observed in non-diabetics ($p>0.05$). In the multivariate analysis, GI remained significantly associated with infection ($p<0.01$; OR 1.27; CI 1.1-1.4), while diabetes was not independently associated with infection ($p>0.05$). **Conclusion:** In the present study, the risk of infection was found to be associated with a prior diagnosis of diabetes mellitus and a higher rate of GI. GI was also identified as a predictor of infection in multivariate analysis, while diabetes was not. However, further research is necessary to gain a deeper understanding of these associations.

Gradenigo syndrome secondary to mucormycosis in an elderly patient: a case report

Nathalye Fernanda Pedroso Dircksen[1], Marcelo Simplicio Carvalho[1], Letícia de Barros Dias[1], Lorena Fernandes Kronbauer[1], Felipe Leonardo Semensati[1], Fábio Gonçalves[1], Walton Luiz Del Tedesco Junior[1], Damacio Ramon Kaimen Maciel[1]

[1]Irmandade da Santa Casa de Londrina, Londrina PR, Brazil.

Correspondence: Nathalye Fernanda Pedroso Dircksen; Email: n.athalye@hotmail.com.

Case presentation: A 63-year-old man with diabetes mellitus was admitted with headache holocranial, paresis and pain in left face of strong intensity (facial and trigeminal nerves). After 3 weeks he developed binocular diplopy horizontal (paralysis in left abducent nerve), in addition to losing 8kg during the period and brief episodes of confusion mental. The magnetic resonance imaging (MRI) in skull showed sinusopathy inflammatory and veiling in cells from the mastoid bilateral, more sharp on the left , suggesting otitis mild media/mastoiditis. The liquor was light proteinorrhaquia. He used clindamycin and ceftriaxone for 10 days, without improvement in the condition. One new skull MRI showed an area of signal alteration compromising the wall posterior sphenoid sinus on the left, sella turcica and cranial portion of the clivus, with peripheral contrast enhancement (abscess), in addition to thickening and enhancement of the plans meningeal from middle cranial fossa left. Based on the above findings, the diagnosis of Gradenigo syndrome (GS) was made and extended the antibiotic therapy to clindamycin and cefepime for 4 weeks, as well as surgical drainage due to the presence of the abscess, with culture what posteriorly pointed mucormycosis. Like this, started treatment with amphotericin liposomal per 14 days, with resolution of the condition. The patient maintained pain in the trigeminal path, with improvement after introduction in carbamazepine and gabapentin. **Discussion:** GS is composed of the triad of facial pain (trigeminal nerve), palsy abducent nerve and acute suppurateve otitis media. It is a rare complication of otitis media chronic what occurs due to petrous apicitis. The abducent and trigeminal nerves are affected due to the proximity to the petrous apex of the bone temporal. Difficultly if manifests at population elderly, mainly at it was post-antibiotic. If not treated he can cause serious complications, as paralysis of the cranial nerves, abscess intracranial, meningitis, venous sinus thrombosis, empyema subdural and death. Computed tomography is the initial diagnostic method, as it detects opacification of petromastoid air cells and bone erosions. MRI provides more details, as involvement nervous, osteomyelitis adjacent and involvement meningeal, as at the case introduced. The isolation of agent causative It is fundamental for guide the treatment, being, at majority of the cases, accomplished treatment conservative with intravenous antibiotics, if necessary tympanoplasty or myringotomy, and in refractory cases, aggressive surgical interventions such as mastoidectomy and apicectomy petrous. **Final comments:** The classic GS triad was present in less than half of the patients from the series original by Giuseppe Gradenigo. Therefore, physicians should be aware of presentations atypical, being essential the assessment radiological immediate andearly use of antibiotics for avoid complications potentially fatal.

Graves' ophthalmopathy from the neurologist's perspective: a case report

Olívia de Mendonça e Morais[1], Danyel Augusto Sousa Castro Oliveira[1], Bárbara Ferreira Nascimento[1], Amanda Soares Pimenta[1], Luis Maximo de Araujo Junior[1], João Henrique da Matta Clementino[1], Daniela Aparecida Lima Viana[1]

[1]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Olívia de Mendonça e Morais; Email: d201911308@uftm.edu.br.

Case presentation: A 38-year-old woman, without previous comorbidities, presented to the Emergency Department complaining of sudden vertical deviation of the right eye concurrent with asymmetry of the upper third of the face for about 3 days. Additionally, she had right periorbital edema, ipsilateral ocular pain without visual changes for 1 week. On physical examination, she exhibited saccadic eye movements on the right, convergent strabismus to the right, and asymmetry of the midface with left eyelid ptosis. A lumbar puncture showed no abnormalities in cerebrospinal fluid, and cranial MRI revealed normal brain findings. Laboratory tests indicated suppressed TSH, elevated free T4, positive anti-thyroid peroxidase antibodies (Anti-TPO), anti-thyroglobulin antibodies (Anti-TG), and Thyrotropin Receptor Antibody (TRAb), suggesting a diagnosis of Graves' ophthalmopathy. The patient showed partial improvement with nearly imperceptible saccadic movements at discharge. She continues to be followed up by neurology and endocrinology specialists on an outpatient basis. **Discussion:** Graves' ophthalmopathy is an autoimmune disease that typically develops in cases of thyrotoxicosis or in patients with a history of hyperthyroidism; however, these ocular changes can precede or follow thyroid dysfunction by up to 18 months. It can occur at any age but is most commonly observed between 20 and 50 years old, with a predominance in women (8 times more frequent than in men). Risk factors include female sex, smoking, hypercholesterolemia, older age at onset, and radioiodine therapy. In 80% of cases, the manifestation involves 2 or more extraocular muscles without tendon involvement. The disease is associated with exophthalmos, staring gaze, diplopia, and rarely, visual loss due to compressive dysthyroid optic neuropathy. Its pathogenesis involves inflammation of periorbital soft tissues, overproduction of glycosaminoglycans by orbital fibroblasts, and adipose tissue hyperplasia. Treatment depends on disease activity (active or inactive) and may include corticosteroids, radiotherapy, or surgical therapy. **Final comments:** Based on the reported case, acute manifestations of Graves' ophthalmopathy were observed, including symptoms of pain on eye movement, conjunctival hyperemia, and unilateral periorbital edema. The described clinical picture is not typically associated with initial manifestations of hyperthyroidism caused by Graves' disease, and combined with other neurological findings, may lead to various differential diagnoses. Therefore, in the presence of evident neurological abnormalities and innocuous laboratory and imaging results, investigating toxic-metabolic causes becomes essential for diagnostic clarification.

Guillain-Barré syndrome after dengue infection: case report

Mayara Tszesnioski Maçaneiro[1], Caio de Lima Ferreira[1], Giuliana Moro[1], Klaus Johann Jacques Schebek Teixeira[1], Felipe Ferreira de Almeida[1], Arthur Stedile Ribeiro Pacheco[1], Giulianna Luzia Pereira[1], Marcos Silvio Gomes[2], Felipe Ibiapina dos Reis[1]

[1]Universidade da Região de Joinville, Joinville SC, Brazil.
[2]Hospital Municipal São José, Joinville SC, Brazil.

Correspondence: Mayara Tszesnioski Maçaneiro; Email: mayaratm.tsz@gmail.com.

Case presentation: An 83-year-old female presented to the Emergency Department with speech alteration, sphincter release, and a fall within the last 24 hours. Examination revealed left-sided hemiparesis, hypoesthesia, and disorientation. Her medical history included systemic arterial hypertension, hypothyroidism, and dyslipidemia, for which she was taking levothyroxine, simvastatin, and losartan. A preliminary diagnosis of stroke in the anterior cerebral region was made, along with a suspicion of Dengue B. Cranial computed tomography (CT) and angio-CT showed no acute lesions or cerebral artery occlusions. She was placed on antiplatelet therapy with clopidogrel and monitored in an acute stroke unit.

Laboratory confirmed positive NS1 and a platelet count of 81,000; hence, Clopidogrel was discontinued due to thrombocytopenia. On the fifth day of hospitalization, her neurological deficits worsened, and she developed dyspnea, dysarthria, dysphagia, and tetraparesis. Guillain-Barré syndrome (GBS) was suspected, and further investigation was initiated. Cerebrospinal fluid (CSF) analysis confirmed the diagnosis of GBS by showing albuminocytologic dissociation (1 cell, 72 proteins). Treatment with immunoglobulin was initiated. Despite immunoglobulin treatment, the patient remained globally weak, necessitating plasmapheresis as an additional treatment. During the treatment, the patient required mechanical ventilation and received Meropenem for ventilator-associated pneumonia. After 48 days post-GBS diagnosis, the patient achieved clinical stability and discharged to a rehabilitation facility. **Discussion:** Dengue, an acute febrile infectious disease endemic in tropical regions, had over 5.2 million cases in Brazil in 2024 transmitted by the mosquito Aedes aegypti, with symptoms ranging from mild (fever, headache, myalgia, arthralgia, rash, and retro-orbital pain) to severe, with 1-25% potential neurological complications like GBS. GBS, an acute polyradiculoneuropathy, often follows infections or vaccination, with a mortality rate of 3-10%. It involves autoimmune mechanisms damaging nerve structures, presenting as ascending muscle weakness and hyporeflexia. Diagnosis includes clinical evaluation, CSF analysis, electromyography, and imaging. Treatment comprises immunoglobulins and plasmapheresis. The association between GBS and dengue is rarely documented in the literature. Nevertheless, GBS can occur as a neurological complication of dengue fever, especially with DENV-2 and DENV-3 serotypes. Inflammatory cytokines from the immune response to dengue may increase blood-brain barrier permeability, contributing to GBS pathogenesis. Moreover, cross-reactive IgM or IgG antibodies against flavivirus antigens are more common in GBS patients. **Final comments:** GBS, characterized by muscle weakness and immune system involvement, can occur post-infection, with dengue being one of the triggering viruses.

https://doi.org/10.5327/CBN240846

Guillain-Barré syndrome after dengue virus infection: an unusual association

Luíza Toledo de Castro[1], Henrique Bernal[1], Ana Flávia Pincerno Pouza[1], Herval Ribeiro Soares Neto[1], Sônia Maria Cesar de Azevedo[1]

[1]Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo SP, Brazil.

Correspondence: Luiza Toledo de Castro; Email: luizavga@hotmail.com.

Case presentation: A 60-year-old man presented walking difficulty five days after dengue fever due to imbalance sensation. He also referred to lower limbs ascending numbness. Three days later, symptoms progressed to the upper limbs.Within one week after symptoms onset, he could not walk without assistance. Neurological exam revealed four limbs proximal weakness (grade 4/5), global areflexia and lower limbs dysesthesia. Regarding deep sensation, he showed a significant impairment: distal hypopalesthesia, sensory ataxia, pseudoathetosis and sensory ataxic gait. Complementary exams showed protein-CSF dissociation (2 cells and 61 proteins). Electrophysiological study showed primarily demyelinating sensory-motor polyneuropathy. Intravenous immunoglobulin (2g/kg) was started and a significant improvement was obtained: the patient was able to walk again. (...) At the outpatient follow-up visit, the patient reported improvement in muscle strength, in addition to progressive improvement in gait. Keeps discreet tingling and hands and feet. It shows the result of a new electroneuromyography performed 40 days after the onset of symptoms, which reveals: non-uniform sensory and motor polyradiculopathy, primarily demyelinating, subacute, with no signs of recent activity. Neurophysiological improvement compared to previous examination. **Discussion:** Guillain-Barré syndrome (GBS) is an acute immune-mediated polyradiculoneuropathy that typically occurs 2 to 8 weeks after a viral or bacterial infection. Dengue virus is an uncommon trigger to SGB. Regarding neurological manifestations due to dengue infection, DENV-2 and DENV-3 are the most associated. Motor function is usually most affected, in an ascending pattern over a period of up to 4 weeks. Areflexia, sensory disturbances, and cranial nerve involvement may also occur. Symptoms onset usually occurs after two weeks from the infection, but may also start concomitantly with dengue fever. Neurological manifestations are due to direct invasion, immune-mediated reactions or metabolic changes. Diagnosis and treatment adhere to the same principles as those for SGB in other contexts**. Final comments:** Although rare, arboviral infections can precede SGB as well as other viruses. This case highlights the importance of topographical diagnosis, leading to recognition of acute sensory-motor demyelinating polyneuropathy triggered by an uncommon cause. Early treatment enabled an almost complete improvement, thereby reducing disease morbidity.

Guillain-Barré syndrome in children: a 10-year retrospective analysis of a Brazilian electrophysiology diagnostic center archive

Rafael Gomes Costa[1], Fernando Cavalcanti de Sá e Benevides Falcão[1], Renata Barbosa Paolilo[1], José Pedro Soares Baima[1], Carlos Otto Heise[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Rafael Gomes Costa; Email: rgc0711@gmail.com.

Background: Guillain-Barré syndrome (GBS) is the leading cause of acute flaccid paralysis in children globally following the eradication of poliomyelitis. Recent studies indicate a potential bimodal age distribution among infants, with the first peak occurring in preschoolers around 2 years old. In young infants, the syndrome may present as hypotonia or motor delay. While lumbar puncture and nerve conduction studies are crucial diagnostic tools, challenges include the child's cooperation and the technical expertise required for performing and interpreting these tests. Mortality rates in children can range from 7-12% in African, Asian, and Latin American populations, compared to zero in European countries. **Methods:** This study was conducted at the Electrophysiology Department affiliated with the Neurology Unit of a major reference center in Brazil. We reviewed all electrophysiological studies conducted between 2013 and 2023 to identify cases suspected of GBS. Patients under 18 years old were included, and their medical records were analyzed to confirm GBS diagnosis according to Brighton's criteria. Electrophysiological studies were conducted for all patients. We also examined the correlation between clinical severity, pathogenic subtypes, and other clinical features. **Results:** Out of 51 exams initially suspected of GBS, 35 were confirmed as GBS cases. The mean age was 8.6 years, with a slight male predominance (51%). A potential triggering event preceding GBS was identified in 82% of patients. Most patients required hospitalization, and half of them were admitted to the ICU. The mean EGRIS score at admission was 2.34, and approximately 68% of patients experienced loss of walking ability before or during their hospital stay. Electrophysiological classification revealed that 60% had the demyelinating variant, while 34% had the axonal form. Three patients showed reversible conduction failure. No statistical difference was found between severity variables and electrophysiological variants. **Conclusion:** In low-income settings, nerve conduction studies are not always necessary for diagnosing and treating GBS. Our study, based on data from an electrophysiology department database, found over a quarter of cases with at least one clinical atypical feature, differing from studies based on broader inpatient databases, certainly representing one of the reasons why the exam is requested by the clinician at first place. The pathogenic subtype does not appear to significantly influence the disease's clinical course, aligning with global literature. Reversible conduction failure may provide new insights into prognosis estimation.

Guillain-Barré syndrome succeeding dengue infection: a case series of three patients

Mayko Nascimento Merscher[1], Gustavo Freitas Alves de Arruda[1], Lucas Vieira Pinto[1], Gabriel Costa dos Reis[1], Alice Jardim Zaccariotti[1], Laura Araújo Paulino[1], Luiz Fernando de Oliveira Urzeda[1], Camila Caroso Lobo[1], Marcio Luiz Figueredo Balthazar[1], Marcondes Cavalcante França Junior[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Mayko Nascimento Merscher; Email: maykomerscher@gmail.com.

Case presentation: CASE 1: A 55-year-old female presented with a 4-day history of headache, myalgia and fever, with a positive IgM serological test for dengue. Nine days after the symptoms onset, she reported numbness, weakness, inability to walk and slurred speech. The physical exam highlighted proximal weakness of upper and lower limbs, global areflexia, bilateral peripheral facial palsy, hypoesthesia, and Laségue sign. Cerebrospinal fluid (CSF), collected in the first week of clinical course, had no abnormalities. CASE 2: A 52-year-old female started a clinical condition of headache, low back pain and lower limbs pain associated with a diagnosis of dengue through a positive IgM test. After 5 days, she developed weakness, inability to walk, burning sensation in feet, and feeding difficulty. On examination, it was found global weakness and areflexia. CSF evidenced albuminocytological dissociation. CASE 3: A 39-year-old female with a history of headache, myalgia, fever and retro-orbital pain, along with positive IgM for dengue, presented after a few days with weakness, sensitivity symptoms, and urinary retention. The neurological exam demonstrated global weakness, areflexia, hypoesthesia, bilateral peripheral facial palsy, dysphonia, and dysphagia. Soon after, she developed the need for mechanical ventilation due to the rapid evolution of the disease with respiratory failure. CSF confirmed albuminocytological dissociation. **Discussion:** Dengue is a viral disease transmitted by infected Aedes aegypti mosquitoes in Brazil, which are also vectors for the transmission of other arboviruses such as zika and chikungunya. Neurological manifestations due to dengue vary between 0.5-21% and represent both direct and indirect complications. Among the possible manifestations, one of the most common is Guillain-Barré syndrome (GBS), which may also occur after oligosymptomatic cases of dengue. In this case series, 3 female patients with a previous dengue infection developed different clinical manifestations, but all of them presented cranial nerves involvement somehow. Only one didn't present protein-cytological dissociation. All were treated with human immunoglobulin and improved during and after the end of treatment. **Final comments:** Through greater serological test availability, it is possible not only to identify dengue cases, but also to better characterize associated neurological complications and its frequency, guiding strategies for mapping and preventing new cases. As it is an endemic disease in Brazil, the description of GBS in oligosymptomatic cases of dengue should draw attention, as the increase of GBS cases without a clear history of previous infection or vaccination might be related to undiagnosed dengue. Therefore, it is essential that risk areas for dengue have the availability of confirmatory exams and also public policies to act in transmission foci of its vector to interrupt the transmission chain, and consequently its complications.

Case presentation: Male, 71 years old, with a bitter taste in his mouth 16 days ago, which progressed to dysarthria and dysphagia for solids, as well as cruralis tetraparesis predominantly, leading to loss of the ability to walk and difficulty holding objects. History of self-limited diarrhea 45 days ago, influenza vaccination 27 days ago, constipation 8 days ago, and significant eye tearing 1 day ago. He have controlled hypertension and social alcohol use. On physical examination: symmetrical facial diplegia with bilateral Bell's sign, global paresis (3+/5 in the lower limbs and 4+/5 in the upper limbs), areflexia in the lower limbs, and hyporeflexia in the upper limbs. MRI of the cranio-caudal axis with no abnormalities. After cerebrospinal fluid collection, due to the high protein concentration observed in the result, the CSF appeared visibly frothy, clear, and slightly xanthochromic, with albumin-cytological dissociation (total protein: 174mg/dL with 0.5cells/μL), indicating the possibility of Guillain-Barré syndrome (GBS), and treatment with immunoglobulin for 5 days was initiated. During the hospitalization, the patient did not show improvement or progression of symptoms. The etiology is still not clearly defined, suggesting that it could have been caused either by recent diarrhea or by a previous vaccination history. Ophthalmologic evaluation revealed blepharitis in both eyes and a nasal pterygium in the right eye. Additionally, due to dysphagia, a nasoenteral tube feeding diet was chosen. **Discussion:** GBS is an acute polyneuropathy whose symptoms include progressive, ascending motor weakness and, in most cases, is secondary to an infectious pathology. The most feared complication of GBS is respiratory failure, caused by bulbar weakness. Treatment with intravenous immunoglobulin (IVIG) is one of the main therapeutic approaches for GBS. IVIG therapy is preferred due to its rapid action and lower incidence of serious side effects compared to plasmapheresis. In many cases, the pathological agent remains unidentified. In patients who had gastroenteritis, infection by Campylobacter jejuni are especially common. An increased risk of GBS following influenza infection, and it´s vacination. **Final comments:** This case illustrates a presentation of GBS and the challenges in its management. Despite timely IVIG treatment, the patient showed no improvement, highlighting the need for close monitoring and possible additional interventions. Albumin-cytological dissociation in the CFS supported the GBS diagnosis, underscoring the importance of comprehensive diagnostic evaluation. Determining the exact cause of GBS is often challenging. Cases following respiratory infections tend to have better outcomes compared to those following gastrointestinal infections like Campylobacter jejuni. It's crucial to monitor GBS cases post-influenza vaccination closely due to potentially worse prognoses and more severe clinical conditions at admission.

A 30-year-old man presented to the neuromuscular disease clinic reporting post-exercise myalgias and hyperCKnemia. His condition was first noted at the age of 20 when he experienced myalgia and muscle weakness after swimming. The patient was, on occasion, referred to the emergency department, where laboratory tests revealed a creatine kinase (CK) level of 70.000, and he was diagnosed with rhabdomyolysis. He denied having had an acute kidney injury at that moment and reported that the CK eventually returned to basal levels with rest. The patient is a doctor and kept track of his CK levels through the following years. He noticed that he often experiences hyperCKemia, frequently asymptomatic, following physical exercise. The patient reported that his brother had three episodes of rhabdomyolysis during his life. Neurological examination was normal during the consult, and a genetic panel for rhabdomyolysis was requested for diagnosis, which revealed a potentially pathogenic heterozygous variant in the GYG1 gene - NM_004130.4(GYG1):c.304G>C (p.Asp102His), associated with myopathy with polyglucosan bodies type II (PGB2). The GYG1 gene encodes the isoform glycogenin-1, a protein involved in glycogen biosynthesis. Pathogenic variations in the GYG1 gene may result in reduced, absent, or functionally abnormal glycogenin-1 protein, leading to defective glycogen synthesis, glycogen depletion in skeletal muscle, and abnormal glycogen accumulation in cardiac muscle. Homozygous or compound heterozygous variants in GYG1 are associated with PGB2, a genetic disease characterized by different clinical phenotypes, ranging from exercise intolerance to progressive proximal weakness with cardiac involvement. The clinicopathological spectrum of GYG1 disease is rapidly expanding. Most cases illustrate a slowly progressive proximal myopathy with or without cardiac involvement starting in adulthood. However, distal, asymmetric, or isolated facial weakness, fluctuating weakness, exertional myalgia, and exercise intolerance are also described. Our patient experienced recurrent episodes of exercise-induced rhabdomyolysis associated with a probably pathogenic heterozygous variant in the GYG1 gene, probably representing a milder clinical phenotype of PGB2. He was instructed to avoid intense physical exercises, and genetic counseling was advised. Heterozygous variants of the GYG1 gene may present with a mild clinical phenotype of PGB2 disease. This case highlights the need to correlate clinical phenotypes and gene variants while investigating possible genetic diagnosis because mutations in the same gene may present with a broad range of clinical spectra.

Case presentation: Case 1. A 54-years-old male underwent to investigation of a congenital myopathy. A delayed motor milestones was informed, with unsupported walk at age 7. Progressively he noted improvement of motor skill, never up to normal. Myalgia was the prominent complain. Examination revealed upper and lower limb girdle weakness (MRC=4), mild hypotonia and hyporeflexia. Motor function measure (MFM) scale total score=83.33%; Dimension (D) D1=69.23%; D2=91.66%; D3=95.23%. CK and cardiac evaluation was normal. EMG showed myopathic pattern and biceps brachii biopsy diagnosed fiber type disproportion. His parents were consanguineous; he had a brother dead in infancy due to muscle disease. Genetic panel showed a biallelic pathogenic variant in HACD1 gene c.373_375+2delsplicesite. Case 2. A 31-years-old female was investigated because weakness and diffuse myalgia. She had to stay in an intensive care unit (ICU) for several days since birth as hypotonic child and walked after age 5. On examination: predominant proximal weakness, myopathic gate, mild diffuse hypotonia, moderate atrophy and hyporeflexia. MFM scale total score=69,79%, D1=33.33%; D2=91.66%; D3=100%. Genetic panel showed homozygotic pathogenic variant in HACD1 gene (c.375_377+2delsplicesite). Patient has consanguineous parents, no similar case in the family. Case 3. A 15-years-old male born after a normal gestation and delivery required an ICU for survival due to hypotonic syndrome. Motor milestones were mild delayed, and several pulmonary infections occurred in infancy. Under motor and pulmonary physiotherapy, he had a good evolution. CK exam was normal. A muscle biopsy showed fiber type disproportion and genetic panel detected c.373_375+2delGAGGT homozygous pathogenic variant in HACD1 gene. Case 4. A 5-year-old male born with Apgar 5 and 6, after normal gestation and delivery required an ICU stay. Evolution resulted in mild motor delay but normal psychological milestones. Examination showed: myopathic gate, global hypotonia and hypotrophy and, normal stretch reflex. MRC was 4+ in arms and 4- in proximodistal muscles of legs. CK and brain MRI were normal. A genetic panel for detected a biallelic variant c.373_375+2delGAGGT in HACD1 gene. His parents have no consanguinity and there is no similar case in the family. **Discussion:** We present four unrelated patients with congenital myopathy caused by homozygous pathogenic variants in HACD1 gene. Clinical main feature was severe hypotonia forcing early life stay in ICU in 3/4 patients. Evolution was benign in all cases. Myalgia was prominent in oldest patients. CK was unremarkable; 3/4 patients' fiber type disproportion was the morphological hallmark. **Final comments:** HACD1-congenital myopathy is a rare disease, described since May/2024 in 13 patients of Asian ancestry. Our presentation highlights the necessity of think in this causative gene in Caucasian patients, whereas none of our patients had oriental origin.

Background: Delirium is a common neurocognitive disorder in medically ill patients, affecting at least one in seven hospitalized patients overall and around half of Intensive Care Unit (ICU) patients. It is characterized by an acute disturbance in attention, awareness, and cognition that tends to fluctuate in severity during the course of the day and is not better accounted for by a pre-existing neurocognitive disorder. Delirium treatment is complex. There is frequent use of antipsychotics in clinical practice despite insufficient evidence. Haloperidol, a first-generation antipsychotic, is often the first-line pharmacological treatment for delirium, particularly for agitation-related events, despite being commonly associated with a higher rate of adverse effects, such as extrapyramidal symptoms (EPS). Second-generation antipsychotics, or atypical, generally have a better side effect profile and have been evaluated for their usefulness in treating delirium. However, studies comparing haloperidol and atypical are limited. **Objective:** To perform a systematic review and meta-analysis of randomized controlled trials (RCTs) comparing haloperidol and atypical antipsychotics in the management of patients with delirium. Our primary objective was to compare their effectiveness, while the secondary objective was to assess the occurrence of extrapyramidal symptoms. **Methods:** We conducted a systematic search of PubMed, Scopus, and the Cochrane Central Register of Controlled Trials for RCTs. The outcomes of interest included overall mortality, changes in delirium scale scores, and the incidence of extrapyramidal symptoms. Due to the use of different delirium scales across studies (DRS-R-98, MDAS, and CGI-S), we used the standard mean difference (SMD) to evaluate this outcome. This approach allowed us to compare effect sizes across studies that used different scales. Statistical analysis was performed using RevMan 5.4, and heterogeneity was assessed using I^2 statistics. **Results:** Our analysis included 12 RCTs with a total of 1,510 patients (57% male), of whom 41.8% received haloperidol. Delirium severity (SMD, -0.03 [95% CI, -0.20 - 0.15]; p=0.78) and overall mortality (OR, 1.26 [95% CI, 0.88 - 1.80]; p=0.20) did not differ significantly between groups. However, patients treated with haloperidol had a significantly higher incidence of extrapyramidal symptoms compared to those treated with atypical antipsychotics (OR 2.72, 95% CI 1.26-5.87; p=0.01). **Conclusion:** The results of our meta-analysis suggest that overall mortality rates and changes in delirium assessment scales do not differ significantly between patients treated with haloperidol and those treated with atypical antipsychotics. However, haloperidol is associated with significantly higher odds of experiencing extrapyramidal symptoms, indicating a potential advantage of atypical antipsychotics in minimizing adverse effects.

We want to report the case of a 61-year-old man from the city of Siqueira Campos, State of Parana - Brazil, with no significant medical history, presented with a 3-month history of generalized weakness, a prominent gait disturbance - "looking like he was drunk," as his daughter said -, and memory loss. He went to see a neurologist and started taking medication for labyrinthitis and antidepressants as well, without any symptomatic improvement. His mental and cognitive state decreased one month into his symptomatic course, and he progressed to temporospatial disorientation, hallucinations, and incoherent speech. He had also developed diffuse myoclonic jerks. He was admitted to the Neurological Department of the tertiary referral hospital, and the investigation included a Brain MRI that demonstrated symmetric T2 and fluid-attenuated inversion recovery (FLAIR) caudate, putamen, and cortical hyperintensities. An EEG showed a diffuse slowing (7Hz) with a normal posterior dominant rhythm and a generalized pattern in frontal regions with periodic sharp-wave complexes that represented 5% of the total activity. The CSF analyses excluded CNS inflammation, and a sample was sent to the specialized clinical laboratory out of the state for research of protein 14-3-3, that was elevated. During the hospitalization, the mental state deterioration continued until he lapsed into a coma, and ventilatory support was needed. He died approximately 8 months after the onset of the symptoms. The Creutzfeldt-Jakob disease is a prion disease and the most common type of spongiform encephalopathy. This protein, cellular prion protein (PrPc) and its misfolded form, prion protein scrapie-type (PrPSc), lead to neurodegeneration. It was described in 1920 by Hans Gerhard Creutzfeldt and later, Alfons Maria Jakob. In humans, the sporadic form (sCJD) is seen in most cases, but other forms are described such as: sporadic fatal insomnia (sFI) and variably protease-sensitive proteinopathy, genetic forms due to mutations in PRNP (familial CJD) or genetic CJD, Gerstmann-Straussler-Scheinker syndrome and fatal familiar insomnia, acquired forms (as iatrogenic CJD), Kuru and variant CJD. The annual incidence is one to two cases per million people. The diagnostic criteria for probable sCJD include a rapidly progressive cognitive impairment and two of the neurological signs: visual or cerebellar disturbance, pyramidal or extrapyramidal signs, myoclonus or akinetic mutism, plus at least one biomarker criterion: elevated levels of protein 14-3-3 in CSF, or MRI or EEG. Or a progressive neuropsychiatric syndrome and a positive PsPSc seeding activity (RT-QuIC positive in CSF or Other fluids or tissues). CJD is always fatal, and most patients die in one year or less. Between 2005 to 2021, 1,576 notifications of CJD suspected cases were registered in Brazil. The states with the highest number of cases reported in the period were São Paulo with 32.5%, Paraná with 12.0% and Minas Gerais with 10%.

Correspondence: Ruan Gambardella Rosalina de Azevedo; Email: ruangambardella@gmail.com.

This case reports a 21-year-old female with stroke-like events and seizures. At eighteen and nineteen years-old she experienced episodes of migranous headache followed by impared awareness motor onset focal seizure to bilateral tonic-clonic. After the last (fifth) event, she complained of left temporal visual loss and anomic aphasia. Physical examination was also marked by: incomplete, disproportionate, left hemiparesis, Babinski and hypoesthesia on left lower limb and bilateral hearing loss. There were no signs of: ocular motricity impairment, dystonia, parkinsonism, myoclonus. Laboratory tests resulted normal for renal, thyroid and liver function. There were normal blood levels of inflammatory markers and ANA test was negative. Ammonia arterial blood level was high two months after the last seizure. Cerebral spinal fluid and blood arterial lactate were high at the follow up. Brain magnetic resonance image described water restriction signs in the cortical aspects of left: inferior parietal lobe, posterior insula and superior temporal gyrus. There were also minor bilateral occipitotemporoparietal subcortical T2/FLAIR alteration signs. Thus, the images were compatible with more than one vascular territory. There were unremarkable changes on echo/electrocardiogram. Electroencephalogram revealed bilateral occipitotemporal paroxysmal activity with right predominance. Audiometry revealed moderate bilateral sensorineural hearing loss. The genetic testing was positive for m. 3243 A>G heteroplasmy mutation, compatible with Mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes (MELAS). This disease results in impaired mitochondrial translation and protein synthesis including the mitochondrial electron transport chain complex subunits leading to impaired energy production. The inability to generate sufficient energy to meet the needs of various organs results in the multi-organ dysfunction observed. At the follow up, the patient is using coenzyme Q10, carnitine, folic acid, riboflavin and lamotrigine (400mg/day), tolerating mild physical exercises without new stroke like events for three years.

Health profile of elderly people with probable cognitive impairment of primary health care

Tainá Reis Martins[1], Wívian Maria Pires Figueredo[1], Ana Luíza Braga e Silva[1], Luciana Colares Maia[1]

[1]Centro Universitário FIPMoc, Montes Claros MG, Brazil.

Correspondence: Tainá Reis Martins; Email: taina2002@hotmail.com.

Background: Population aging is a reality in Brazil and in the world, generating a need for promoting healthy aging. The change in the epidemiological profile determines that chronic non-communicable diseases (NCDs), such as dementia, are more frequent. Therefore, cognitive decline is a condition ranging from mild cognitive decline to major cognitive impairment or dementia syndrome. **Objective:** To analyze the health profile of the elderly with evidence of cognitive impairment in Primary Health Care (PHC). **Methods:** This is a cross-sectional study conducted in PHC in northern Minas Gerais. Sampling was performed in two stages and by clusters. Initially, the regional health centers of the municipality were drawn and, in each pole, the teams of the Family Health Strategy (FHS) and respective areas of coverage were drawn. 201 elderly people with probable cognitive decline were evaluated, and the Mini Mental State Examination (MMSE) was used for cognitive screening. It is reiterated that the research was approved by the Ethics and Research Committee - Opinion n. 1.628.652. **Results:** We identified 142 women (70.6%) and 59 men, it is noteworthy that the age ranged from 60 to 74 years (41.8%), 75 to 84 years (23.9%) and 85 years and over (34.3%). Through the Clinical Functional Vulnerability Index (CFVI-20), 70.6% (142) were considered fragile, that is with loss of functionality. In addition, 29.9% (60) had urinary incontinence, 53 elderly (31.9%) smoked, and 19.4% (36) were obese. Diseases such as diabetes (21.4%), insomnia (46.3%) and hypertension (67.7%) were also observed in the study population. **Conclusion:** It was found that the profile of the elderly with probable cognitive impairment of the research was characterized

by being the majority of women aged between 60 and 79 years, presenting risk of frailty by the CFVI-20 and also associated diseases such as obesity, diabetes, insomnia, fragility and hypertension. Therefore, cognition can be defined as a predictor of well-being, and its impairment can affect functional capacity in old age, in addition to providing opportunities for loss of autonomy and independence. The importance of NCDs control and the development of promotion strategies, as well as health prevention are essential for healthy and quality aging.

Healthcare journey for patients with amyotrophic lateral sclerosis (ALS) in a specialized service in Salvador-Bahia

Marie Lidio dos Santos Galvão Ribeiro[1], Ariele Amaral Alves[1], Laís Brandão Mota[1], Luna Souza Silva Vilanova[1], Rafael Amaral Albuquerque[1], Têmis Maria Félix[2], Marcela Câmara Machado-Costa[1], Marilaine de Matos Menezes Ferreira[1], Debora Borges dos Santos Pereira[3], Thiago Godoy de Oliveira[3]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.
[2]Hospital de Clínicas de Porto Alegre, Porto Alegre RS, Brazil.
[3]MAPESolutions, São Paulo SP, Brazil.

Correspondence: Marie Lidio dos Santos Galvão Ribeiro; Email: marielidiogr@gmail.com.

Background: The JAV-RARAS study is an integrated initiative within the Brazilian Rare Diseases Network (RARAS), with the objective of measuring the Value of Healthcare Journey (JAV) of patients with rare diseases in Brazil. **Objective:** To evaluate the healthcare journey for patients with Amyotrophic Lateral Sclerosis (ALS) in a specialized service. **Methods:** Patients were followed through the collection of data from medical records and clinical questionnaires. The data obtained was compared to the Clinical and Therapeutic Guidelines (PCDT) defined for ALS, developed by the Brazilian Ministry of Health. **Results:** A total of 30 patients were included in the study, although 2 patients had not undergone any diagnostic tests and 4 patients had no information regarding the types of tests that had been performed. The sample was analyzed for a total of 24 patients. The principal diagnostic tests conducted were as follows: 1. Neurological tests, such as electromyography of four limbs (EMG), magnetic resonance imaging (MRI) of the lumbar and thoracic spine, MRI of the brain and craniocervical junction, and cerebrospinal fluid analysis. 2. Laboratory tests, such as Complete blood count (CBC); measurements of creatinine, alanine aminotransferase (ALT), aspartate aminotransferase (AST), C-reactive protein (CRP), and urea; prothrombin time; and serum protein electrophoresis. **Conclusion:** In accordance with the PCDT for ALS, complementary tests must be conducted to support the diagnosis of ALS and to rule out other systemic disorders that may mimic it. For an accurate diagnosis, every patient suspected of having ALS must undergo complementary tests with results consistent with the disease. These include EMG of four limbs showing denervation in more than one segment and normal motor and sensory nerve conduction (except when there is an associated polyneuropathy); complete blood count, urea, creatinine, ALT, AST, and prothrombin time should be normal. In select instances, at the discretion of the attending physician, the following tests may be requested: An MRI of the brain and craniocervical junction, which should not show any structural lesion explaining the symptoms. Additionally, measurement of the concentration of CRP and serum protein electrophoresis is recommended. These tests should yield normal results. Following a comprehensive analysis, it can be confirmed that the service adheres to the PCDT recommendations for accurate ALS diagnosis. A comparison of this information with the tests performed on the patients in the sample revealed that all recommended diagnostic tests in the PCDT were performed (EMG, MRI, cerebrospinal fluid analysis). Additionally, all recommended laboratory tests were also performed (CBC, renal function, ALT, AST, prothrombin time, CRP, protein electrophoresis). The performance of these tests demonstrates the team's effort to investigate and characterize the clinical manifestations of ALS in this group of patients.

Healthcare professionals perspectives on palliative care for stroke patients: the passar study

Thales Pardini Fagundes[1], Túlio Maranhão Neto[1], Lucas Gondim Briand Vieira[1], Victor Augusto Zanesi Maciel[1], Juliana Pelegrin[1], Mateus Gustavo Favaro[1], Millene Rodrigues Camilo[1], Octávio Marques Pontes-Neto[1]

[1]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Ribeirão Preto SP, Brazil.

Correspondence: Millene Rodrigues Camilo; Email: millene.camilo@gmail.com.

Background: Palliative care should be addressed to all patients with severe or life-threatening stroke. However, its implementation remains challenging despite guidelines. Understanding healthcare professionals' attitudes and practices regarding palliative care is essential for developing targeted interventions to improve palliative care delivery in stroke management. **Objective:** To explore healthcare professionals' perceptions and practices regarding palliative care for stroke patients, focusing on differences in symptom management and care strategies based on professional experience. **Methods:** A cross-sectional, questionnaire-based study was conducted from August to October 2023. One hundred twenty-four healthcare professionals (47 neurologists, 77 other professionals) with at least one year of stroke care experience were included. Data were collected via online questionnaires and analyzed descriptively. **Results:** (1) Demographics: Among neurologists, 55.32% were male with a median age of 29, while 72.73% of other professionals were female with a median age of 31. 38.3% of neurologists and 15.58% of other professionals had one year of stroke care experience. (2) Palliative Care Experience: 55.32% of neurologists and 53.25% of other professionals reported participating in a few palliative care discussions, while 23.4% of neurologists and 36.36% of other professionals had no contact with the topic. (3) Assessment Tools: On a 5-point scale, neurologists reported using the SPICT tool with a mean score of 1.94, and the PPS scale with a mean score of 2.06. Other professionals scored 2.01 and 2.13 respectively. (4) Patient-centered Care: Neurologists reported asking about patients' illness expectations with a mean score of 3.72 out of 5, compared to 3.08 for other professionals. (5) Symptom Management: On a 5-point knowledge scale, neurologists reported the highest competence in pain management (mean 2.7) and the lowest in hypodermoclysis (mean 1.9). (6) Clinical Decision-making: On a 5-point comfort scale, neurologists felt most comfortable not conducting serial laboratory tests (mean 2.72) and least comfortable performing palliative extubation (mean 2.1). (7) Multidisciplinary Approach: Neurologists reported providing multidisciplinary team support with a mean frequency of 3.8 out of 5 and requesting specialized palliative care team evaluation with a mean of 3.2 out of 5. (8) Spiritual Care: Neurologists offered spiritual support to patients with a mean frequency of 2.4 out of 5, and to families with a mean of 2.2 out of 5. **Conclusion:** The study reveals significant variations in the palliative care approach based on professional background and experience level. These findings highlight the need for targeted education and interdisciplinary collaboration to improve palliative care delivery in stroke management.

Heidenhain variant of Creutzfeldt-Jakob disease hiding in plain sight: clinical evolution and sequential MRI analysis of brain degeneration

Marco Antônio Delazeri[1], William Alves Martins[1], Lucas Porcello Schilling[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Marco Antônio Delazeri; Email: marco.delazeri@outlook.com.

A 65-year-old woman presented to our service complaining of dizziness and vertigo lasting two weeks. She exhibited horizontal nystagmus and mild unsteadiness of gait. Initial MRI findings were negative for lesions, and she was prescribed anti-vertiginous medications. However, subsequent evaluation due to progressive cognitive decline revealed focal left parieto-occipital hypometabolism on PET scan. During examination, she displayed mild nystagmus, ataxia, and an upper right visual deficit. A week later, she began stumbling on furniture at home, particularly on the right side, attributing it to blurred vision. Re-examination of the initial MRI revealed slight diffusion-weighted imaging (DWI) restriction in the left occipital region, which progressed in subsequent MRI. She was adimitted for further investigation, with cerebrospinal fluid (CSF) studies showing mildly elevated protein levels. Shortly after, she started exhibiting paraphrastic errors (substituting simple words) and behavioral disturbances. This progressed to extreme multifocal myoclonus triggered by light touch, sound, and post-stimulation, accompanied by an intense startle response, aphasia, and bedridden status. A new Protein 14-3-3 returned negative. Initial EEG findings indicated a slowed background evolving into periodic generalized discharges. Intravenous immunoglobulin (IVIG) and methylprednisolone pulse therapy for suspected autoimmune encephalitis proved unsuccessful. Eventually, a diagnosis of probable Creutzfeldt-Jakob disease (Heidenhain variant) was made. Symptomatic medications partially alleviated the myoclonus. Follow-up MRIs demonstrated severe progression of atrophy and leukoencephalopathy, with DWI lesions extending bilaterally to the caudate, putamen, and ipsilateral insula. Over time, the patient became mute, bedridden, and required nasogastric tube feeding. She passed away a year and a half after diagnosis. The Heidenhain variant of CJD, first described in 1954 and clinically characterized by significant visual impairments (hemianopia, cortical blindness, optical hallucinations, palinopsia, or metachromatopsia), occurs in 3.7-20% of CJD cases, with an annual incidence of 1 case per 1 million people. Molecular and histopathological typing in 23 cases has linked this variant to the MM1 sCJD type. In a large series of 370 patients, Heidenhain was diagnosed in only 18 (4.9%), which showed that MM2 may be present and have a more protracted course, such as in our case. Typical brain findings include DWI and FLAIR hyperintensities in the occipital-parietal region, initially overlooked on MRI. PET imaging may aid in early detection by showing hypometabolism. Progressive cortical atrophy, white matter hyperintensities, and loss of gray and white matter characterize disease evolution on MRI. This case underscores the importance of recognizing this rare variant of CJD and provides a clinical-radiological framework for understanding its progression.

Hemiballism-hemichorea as the initial presentation of type II diabetes refractory to adequate glycemic control: a case report

Luan Yudi Prando Kasuga[1], Melissa Caroline Godoi Prestes[1], Ádria Rodriges da Silva[1], Bruna Beppler[1], Caroline Zapelini[1], Lia Maki Hatisuka Imai[1], Gabriel Rodrigues Espelho Rossi[1]

[1]Universidade Estadual de Londrina, Londrina PR, Brazil.

Correspondence: Melissa Caroline Godoi Prestes; Email: melissa.caroline@outlook.com.

Case presentation: A 69-year-old male with a history of hypertension, dyslipidemia, and overweight, who had irregular medication use, was admitted to a tertiary hospital due to sudden onset of involuntary movements in his left upper limb that began three days prior, associated with forced blinking and involuntary cervical rotation. On physical examination, hemichorea-hemiballismus was observed in the left upper limb, worsening during distracting maneuvers. There was no nystagmus or signs of meningeal irritation. Muscle strength was globally grade V, and no other abnormalities were noted. Laboratory tests showed a hemoglobin A1c of 12.7% and capillary glucose reaching 534mg/dL, leading to a diagnosis of type 2 diabetes mellitus upon admission. Insulin therapy was initiated, and after four days, with persistence of the movements associated with hemiballism, valproic acid 250mg every 12 hours was started. Due to clinical stability and negative infection screening, the patient was discharged on valproic acid, and outpatient follow-up was initiated. After two months, there was a partial reduction in choreic movements. Cranial magnetic resonance imaging (MRI) showed a hyperintense T1 signal in the right striatum, which may correspond to gemistocytic degeneration related to non-ketotic hyperglycemia-induced hemichorea-hemiballism. After eight months, there was partial improvement of the hemichorea, although movements persisted despite adequate glycemic control, and the patient continued with outpatient follow-up and medication. **Discussion:** Hemichorea secondary to non-ketotic hyperglycemia is one of the manifestations of uncontrolled diabetes mellitus. It has been suggested that hyperglycemia may induce anaerobic metabolism, leading to the utilization of GABA as an alternative energy source in the absence of ketone bodies. The clinical presentation includes hemiballism, which differs from chorea due to the larger amplitude of movements and commonly affects the proximal region of limbs, such as the shoulders. Diagnosis is based on the association of clinical findings with imaging results the presence of a hyperintense T1 signal in the putamen contralateral to the hemiballism on MRI. It is considered a benign phenomenon with a good prognosis, and in most cases, glycemic control is sufficient for the resolution of choreiform movements within days. Persistence is rarer and appears to be related to neuronal death or partial dysfunction resulting from hyperglycemia-induced stress in the striatum. **Final comments:** Undiagnosed diabetes mellitus should always be considered in patients presenting with hemichorea or hemiballism. Restoration of euglycemia leads to symptom resolution in most cases, but persistence may require medication with dopamine receptor antagonists. This case highlights the importance of recognizing neurological symptoms as manifestations of metabolic dysregulation in diabetic patients, emphasizing the complexity of managing this condition.

Hemiconvulsion-hemiplegia epilepsy syndrome associated with variant in the CACNA1A gene

Lucas Do Rego Barros Correa Martins[1], Caique Alberto Dosualdo[1], Matheus Hisamitsu Facine[1], Humberto Ramos Crispim[1], Nasser Faiçal Abou Zeenni[1], Ricardo Kendy Nishiuchi de Paiva[1], Antonio Lourenço Pires Neto[1], Laura A. M. Montouro[1], Amanda Leme da Silva Campinas[1], Eduardo de Paula Estephan[1,2]

[2]Universidade de São Paulo, Faculdade de Medicina, São Paulo SP, Brazil.

Correspondence: Lucas do Rego Barros Correa Martins; Email: lucasrbcmartins@gmail.com.

Hemiconvulsion-Hemiplegia-Epilepsy syndrome (HHE) is a rare neurological condition characterized by episodes of hemiconvulsions followed by transient or permanent hemiplegia, along with recurrent epileptic seizures. Among few others syndromes the CACNA1A gene have been associated with HHE, but the clinical course, specific features and response to treatment are not totally elucidated. **Case presentation:** 20-year-old Brazilian male has experienced seizures since infancy. Throughout childhood, he experienced two types of seizures: brief episodes of staring and chewing movements occurring weekly, and longer tonic-clonic seizures affecting the right side of the body, accompanied by ocular deviation, head version, and drooling, sometimes lasting up to approximately 15 minutes, necessitating emergency care. Cognitive delay, with difficulties in reading and writing, was noticed by his mother during this period. On first assessment at our center, the patient reported daily focal seizures with impaired awarenes and monthly episodes of hemiconvulsions, which necessitated emergency care frequently. Episodes of agitation and aggression were also common. Physical examination indicated high-arched palate and low-set ears, dysarthric speech, global hyperreflexia, and extensor plantar reflex bilaterally. Throughout his life, the patient has been treated with topiramate, clobazam, levetiracetam, and most recently with valproic acid, lamotrigine, carbamazepine. Diagnostic workup included normal EEGs and MRI showing no structural lesions. New generation sequencing genetic test (panel) identified a heterozygous variant in the CACNA1A gene (p.Tyr62His ENST00000360228). Then patient was put on acetazolamide, with gradually increasing dose, up to 500mg twice a day. The seizures, which were daily before, had a sharp reduction to a frequency of two episodes monthly. **Discussion:** HHE profoundly impacts patients' quality of life. This case illustrates the syndrome's complexity, with frequent seizures resistant to treatment. Managing HHE remains challenging, necessitating multidisciplinary interventions to control seizures and support neuropsychomotor development. Early identification and appropriate intervention are crucial for improving prognosis and quality of life. Seizures response to acetazolamide is not well established on literature, but in our case had a clear effect, suggesting an option to treat this often refractory epilepsy.

[2]Universidade Federal do Estado do Rio de Janeiro, Hospital Universitário Gafrée e Guinle, Rio de Janeiro RJ, Brazil.

Correspondence: Lucas Gonçalves Coelho; Email: lucasgcoelho@edu.unirio.br.

Case presentation: A 45-year-old male patient reports the onset of severe lower back pain in 2013. After numerous visits to the emergency room, he underwent the insertion of a double J catheter due to the diagnosis of nephrolithiasis, with no improvement in the pain. Subsequently, due to a case of constipation, he was admitted for the treatment of paralytic ileus and, with persistent pain, underwent an appendectomy due to suspected appendicitis. With worsening abdominal and lumbar pain, he underwent two exploratory laparotomies, including cholecystectomy, without any diagnostic definition or clinical improvment. The patient developed ascending sensorimotor polyneuropathy and acute respiratory failure, leading to admission to the ICU and dependency on mechanical ventilation. Still during hospitalization, therapy for Guillain-Barré syndrome was conducted without improvement. After two months of symptoms onset, while in the ICU, the hypothesis of hepatic porphyria was raised. Upon confirmation of the diagnosis through porphobilinogen and delta-aminolevulinic acid testing in urine samples, appropriate treatment was initiated, leading to clinical improvement and discharge. During follow-up at the outpatient clinic, molecular genetic testing was performed and was positive for a pathogenic variant of the CPOX gene, confirming the diagnosis of hereditary coproporphyria. **Discussion:** Porphyrias are a group of rare manifestations caused by enzymatic impairment in the heme production pathway, resulting in the accumulation of neurotoxic byproducts. One subtype of this condition is hereditary coproporphyria, caused by the presence of a pathogenic variant of the CPOX gene. This rare disease has a wide spectrum or non-specific manifestations, ranging from cutaneous symptoms to abdominal and neuropsychiatric conditions. In the presented case, it is evident that the lack of pathognomonic symptoms, combined with the rarity of the disease, complicates the diagnosis and initiation of treatment in patients with the condition, often leading to invasive procedures that could have been avoided. **Final comments:** Including porphyrias as a differential diagnosis in acute neurovisceral conditions is crucial to facilitate the early identification of these conditions. Therefore, specific laboratory and molecular genetic testing are essential for the accurate diagnosis. With the proper diagnosis and treatment, it is possible to control the progression of the disease, in addition to significantly improving the quality of life and reducing mortality associated with hereditary coproporphyria.

[4]Clínica de Neurofisiologia Luiz Carlos Pinto, Rio de Janeiro RJ, Brazil.

Correspondence: Caroline Bittar Braune; Email: caroline.bittar@gmail.com.

Case presentation: A 78-year-old male was evaluated with a history of bilateral facial paralysis for 25 years. He reports that he was asymptomatic until age 53, when he noticed facial asymmetry. He underwent a cranial magnetic resonance imaging, which was normal, and neurophysiological studies showed axonal damage to the facial nerves with signs of reinnervation, but no further investigation was carried out. At the age of 69, he developed new motor difficulties bilaterally in the face, with a diagnosis of new facial paralysis. At the age of 73, he noticed gradual binocular visual loss and was diagnosed with glaucoma. He had a previous diagnosis of systemic arterial hypertension and type 2 diabetes mellitus. Regarding his family history, his mother died at the age of 85 with facial weakness and binocular amaurosis secondary to glaucoma. His neurological examination revealed facial diplegia with bilateral Bell's sign, global apalesthesia, binocular ophthalmoparesis, in addition to "cutis laxa". Neurophysiological studies showed chronic neuropathy of the facial nerves and chronic axonal sensory-motor polyneuropathy. In a new ophthalmological evaluation, corneal biomicroscopy established the diagnosis of corneal lattice dystrophy. Considering the phenotype characterized by slowly progressive cranial neuropathy with

predominant involvement of the facial nerves, associated with polyneuropathy, "cutis laxa" and corneal lattice dystrophy, with positive family history, the diagnostic hypothesis of hereditary gelsolin amyloidosis was established, and genetic test was requested. **Discussion:** Hereditary gelsolin amyloidosis (HGA) is a rare autosomal dominant disease most likely caused by sporadic low-frequency mutations in the gelsolin gene (GSN). It was initially described by the Finnish ophthalmologist Dr. Meretoja, and cases were subsequently noticed in several countries, although the disease may still be underdiagnosed. Gelsolin is a principal actin-modulating protein, implicated in multiple biological processes including the nervous system, e.g. axonal transport, myelination, neurite outgrowth, and neuroprotection. GSN defect causes expression of variant gelsolin, followed by systemic deposition of gelsolin amyloid. HGA symptoms start in the third or fourth decades of life, typically emerging as a classical triad of ophthalmological (corneal lattice dystrophy type 2), cutaneous (cutis laxa) and nervous system involvement, with slow progression. Progressive bilateral facial palsy is typical, with initial involvement of the upper and later lower nerve branches. HGA may manifest with further neurological (i.e., other cranial nerves involvement, peripheral and autonomic neuropathy) or systemic features, including cardiac and renal abnormalities. **Final comments:** HGA is a rare condition, but it presents a characteristic phenotype and should be considered as a differential diagnosis of multiple and progressive cranial neuropathies, especially facial diparesis.

Hereditary neuropathy with liability to pressure palsies (HNPP): a diagnostic challenge

Geovanna Barros Rocha[1], Lucas Miquilini de Arruda Farias[1], Fernando Tavares Brasil Teixeira[1], Raissa Prata Meireles[1], Douglas Ferreira Pereira[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Geovanna Barros Rocha; Email: geovannaroccha@outlook.com.

Case presentation: F.T.S., 42 years old, male, white. The patient reported a year ago that he noticed loss of strength in his left hand, associated with hypotrophy of the thenar region and also high-frequency tremor, both at rest and in movement. He had a similar episode 10 years ago, which resolved spontaneously with daily activities. Exams: Electroneuromyography of the left upper limb (26/10/23) - Peripheral, sensory-motor neuropathy, with multiple compressive lesions of the ulnar and median nerves. Magnetic resonance imaging of the left elbow (01/23/24) - slight thickening with changes in the ulnar nerve signal. Physical examination of the left upper limb: Strength 3, Mingazzini and Froment positive. Hypoesthesia in the path of the ulnar nerve. Negative Allen, Tinel, Phallen and Adson maneuvers **Discussion:** This is a rare case of Hereditary Neuropathy with Susceptibility to Pressure Palsy (NHPP), with episodic and recurrent characteristics, with an incidence of 2-5/100,000, with autosomal dominant inheritance and involvement of chromosome 17 (80-85%): 17p11.2. The clinical manifestations, despite the variety of phenotypes, are classic, with gradual and progressive weakness, asymmetrical and episodic, with a long evolution, just like the case presented by the patient. The diagnosis is made by performing electroneuromyography, which shows slowness in the conduction fibers, as well as by carrying out genetic tests. There is still no treatment available for peripheral mononeuropathies, only physiotherapy, occupational therapy and some orthopedic procedures to avoid atrophic complications in the future. The presented patient is progressing well with physiotherapy and outpatient follow-up. **Final comments:** Despite the absence of family history and molecular tests, the diagnosis of NHPP can be made with clinical history and examinations. It is necessary to establish the diagnosis as early as possible, with the aim of starting motor rehabilitation treatment and avoiding complications, in addition to allowing genetic counseling to be carried out in the family. Even though it is a rare disease, it represents an important study, due to the complexity of the diagnosis and the possibility of evolution.

Hereditary spastic paraparesis associated with SPG11 gene: a case report

Victória Nunes Alvares[1], Fernanda Dias Guimarães Almeida[1], Wesley Gabriel Silva de Morais[1], Lucas Gonçalves Coelho[1], Tatyane Andrade de Souza Silva[1], Vanessa Conceição Saar Mautone Lima[2], Luan Henrique Honório Rocha[2], Karina Lebeis Pires[2]

[1]Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.
[2]Universidade Federal do Estado do Rio de Janeiro, Hospital Universitário Gafrée e Guinle, Rio de Janeiro RJ, Brazil.

Correspondence: Victória Nunes Alvares; Email: victoriaalvares@edu.unirio.br.

Case presentation: A 38 year-old female presented with lower limb weakness, mainly on the right, and daily-long lasting cramps that started after a cesarean delivery at age 30 was referred to our neurology department. On physical evaluation, the patient presented a spastic gait, only being able to walk with support as she was restriced to a wheelchair. She also presented hypertonia and clonus in lower limbs; generalized muscle weakness, specially in the feet; global hyperreflexia with increased reflex area; dysdiadochokinesia and dysmetria in the index-nose test. An in-depth investigation was carried out and, as infectious and rheumatological causes were ruled out, a brain magnetic resonance imaging (MRI) was requested. The exam showed tenuous hypersignal in the white matter adjacent to lateral ventricles in T2 and FLAIR sequences, diffuse thinning of the corpus callosum and a discrete accentuation of the cortical grooves and fissures. Cervical, thoracic and lumbosacral spine MRI didn't show any pathological alterations. The investigation proceeded and an electroneuromyography was performed on the patient, showing results consistent with diffuse preganglionic axonal involvement reaching neural structures that supply the L3-L4-L5-S1 myotomes. Therefore, genetic molecular testing was requested and showed the presence of a mutation of the SPG11 gene (OMIM*610844), consistent with hereditary spastic paraparesis type 11. **Discussion:** Hereditary spastic paraparesis (HSP) represents a heterogenous group of inherited rare diseases in which the main clinical feature is the progressive lower limb weakness and spasticity. Although most studies indicate that the onset of clinical features occur in adolescence, it does not rule out the possibility of a late manifestation of symptoms, as it was seen in the case presented. The diagnosis of HSP is hampered by the difficulty to access the genetic molecular testing and also the wide range of genetic conditions that it may be associated with, as well as the variety of intensity of clinical symptoms that patients with the same mutation may present. Therapeutic options include pharmacological treatments to manage mainly the spasticity and a multidisciplinary approach, including especially physiotherapists and speech-language pathologists, to prevent possible complications, such as paraplegia, dysarthria and dysphagia. In this case report, the late onset of symptoms and late diagnosis compromised the early start of adequate treatment, thus stimulating the progression of the disease. **Final comments:** HSP associated with the SPG11 gene is rare neurological disease that has a challenging diagnosis, even though clinical symptoms and imaging findings may be characteristic. Therefore, we emphasize the significance of early diagnosis as the pharmacological treatments and multidisciplinary approach prove to be beneficial in the improvement of the quality of life of our patients.

Correspondence: Juan Sebastián Sánchez León; Email: juansebastian1516@hotmail.com.

Case presentation: 48 years old woman without significant family history and comorbilities presented with a slowly progressive history of weakness in the left lower limb since 30 years old. After few months, she presents involvement of the right lower limb, with gradual worsening of gait, needing to use crutches. Subsequently, present mild dysphagia and dysarthria. The symptoms worsening very slowly and they stabilized the last years. The patient's neurological exam showed crural paraparesis, global hyperreflexia, spasticity in all 4 limbs, ataxia, positive bilateral Babinski and Hoffman signs. In addition to the neurological symptoms she has joint pain, xerostomia and xerophthalmia. We performed MRI of brain and spinal cord without alterations. Blood and serological tests: vitamin B12, serum copper, anti-HTLV-1, anti-CCP, rheumatoid factor, anti-SM, anti-SSa, anti-SSb, anti-histona, anti-RNP, anti-GAD all negative and positive ANA (1:320 BAC-3 pattern). We decided to make a chest tomography, biopsy of salivary glands and ophthalmological evaluation all of them without alterations, ruling out the diagnosis of Sjogren's syndrome. Genetic tests negative for SCA 1,2, 3, 6, 7, 10, 12, 17. Not having diagnosis and high clinical suspicion of hereditary disease, we request complete Genome Sequencing showed: homozygous variant NM_005186.4(CAPN1):c618_619del:p.(Gly208Glnfs*7). The result confirms diagnosis of hereditary spastic paraplegia 76 (HSP76) with involvement by the CAPN1 gene. With the diagnosis we decided to make genetic counseling. **Discussion:** Hereditary spastic paraplegia (HSP) is a heterogeneous group of neurodegenerative diseases with approximately 91 associated loci. HSP76 is an autosomal recessive disease that was described for first time in 2016 and is characterized by presenting spasticity in legs, ataxia, dysarthria and peripheral neuropathy. For the low prevalence and difficulty in accessing to specific tests the diagnosis of HSP is challenging. There's less than 50 cases reported in the world. The disease is caused by CAPN1 gene variants. The phenotype of the disease is characterized for mild or moderated symptoms with early onset and subsequent stabilization of the disease. **Final comments:** Althought there is no disease-modifying treatment, a genetic evaluation is necessary in case suspect of hereditary spastic paraplegia, to start genetic counseling, symptomatic treatment (baclofen, tizanidine, botulinum toxin) and rehabilitative medical therapy.

https://doi.org/10.5327/CBN240866

Hereditary spastic paraplegia, Kjellin syndrome: clinical findings that may go unnoticed

Caroline Vianna Costa Pinto[1], João Henrique Reis Duque Estrada[1], Luiza Póvoa de Souza Guimarães[1], Victor Waldhelm Cozer[1], Diogo Matheus Terrana de Carvalho[1], Felipe da Rocha Schmidt[1], Sofia Abreu Mermelstein[1]

[1]Universidade do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Caroline Vianna Costa Pinto; Email: carol.vianna.cp@gmail.com.

Case presentation: A 44-year-old man presented to the neurology outpatient clinic complaining of lower back pain and difficulty walking. He reported progressive difficulty over the past 8 years, initially with running, then with dressing, climbing up and down stairs, and eventually with walking. On examination, he exhibited spastic rigidity in the lower limbs with mild asymmetry (worse on the right), symmetrical hyperreflexia with inexhaustible clonus in the lower limbs, and bilateral Babinski sign. Muscle strength was graded 4+ in the lower limbs symmetrically. He denied consanguinity in the family, but mentioned having 6 siblings, including two sisters and four brothers, one of whom had a similar condition. This brother, aged 41, also had spastic rigidity with hyperreflexia, but with exhaustible clonus bilaterally, right-sided Babinski sign, flexor plantar response on the left, and hypoesthesia in a stocking distribution. Both brothers denied visual changes and exhibited intellectual deficit with executive dysfunction, episodic memory deficit, and language impairment. Ophthalmological evaluation revealed retinal pattern dystrophy in both brothers. Cervical and dorsal spine MRI showed no abnormalities, while cranial MRI in both patients revealed discrete foci in the white matter with T2 hyperintensity and T1 hyposignal, suggestive of the ears of the lynx sign. Given the clinical history, and exclusion of diferential diagnosis like infectious and immune-mediated etiologies, the hypothesis of Kjellin syndrome, hereditary spastic paraplegia (HSP), was raised and confirmed by genetic testing showing a mutation in the SPG 11 gene. **Discussion:** HSP is a disease characterized by chronic and progressive spastic paraparesis, with other possible associated symptoms depending on the specific subtype, such as ataxia, dementia, and retinal changes. Currently, there are descriptions of at least 87 genes associated with this disease. The presented case highlights the importance of comprehensive investigation in these patients, including fundoscopy, searching for associated signs and symptoms, and active screening of affected family members. The combination of retinal dystrophy, ears of the lynx sign, and corpus callosum hypoplasia on MRI, should prompt the neurologist to consider hereditary spastic paraplegia due to mutations in the SPG 11 or SPG 15 genes. **Final comments:** The objective of this case report is to emphasize the importance of clinical findings even in a rare disease in which genetic testing plays a prominent role, aiming to reinforce the importance of a comprehensive diagnostic investigation that often brings us very close to the definitive diagnosis.

https://doi.org/10.5327/CBN240867

Hereditary transthyretin amyloidosis (ATTRv) mimicking motor neuron disease: importance of considering this differential diagnosis

Cleberson Alberceli Vieira de França[1], Mayhara Rosany da Silva Santiago[1], Renata Amaral Andrade[1]

[1]Hospital Pelópidas Silveira, Recife PE, Brazil.

Correspondence: Cleberson Alberceli Vieira de França; Email: cleberson.avf@gmail.com.

Case presentation: Case 1: A 71-year-old male patient presented with symptoms of progressive dysphonia and dysphagia, progressing to fasciculations, weakness, and atrophy in the upper limbs. He reported significant weight loss over the past year and a history of bilateral carpal tunnel syndrome. There was no family history of polyneuropathy. Electroneuromyography (ENMG) revealed chronic pre-ganglionic involvement in bulbar and cervical segments, as well as bilateral median nerve impairment. Exome sequencing: pathogenic mutation in the TTR gene (p.Val142Met). Case 2: A 58-year-old female patient exhibited progressive weakness in the lower limbs, initially distal and evolving over 2 years to involve both proximal and distal muscles of the upper limbs, along with dysphonia and episodes of choking. She had a history of chronic diarrhea. Examination showed tongue atrophy and fasciculations, predominantly distal tetraparesis, global areflexia, and tactile and painful hypoesthesia with a gradient in the lower limbs. ENMG: denervation in bulbar, cervical, thoracic, and lumbar segments, predominantly distal, with absent sensory potentials in the lower limbs and reduced motor potentials dependent on length. Gene sequencing of TTR: pathogenic mutation (p.Ile127Val). Case 3: A 75-year-old male patient presented with mild symptoms of paresthesia in the feet progressing to tetraparesis and dysphagia over 5 years. There was no family history of polyneuropathy. Examination: distal flaccid and areflexic tetraparesis, global muscle hypotrophy, and fasciculations in the tongue, cervical, and lumbar segments. Bilateral hypopallesthesia in the hallux was noted. ENMG: chronic pre-ganglionic involvement in bulbar, cervical, and lumbosacral segments with signs of acute denervation. Associated sensory polyneuropathy was also observed. Gene sequencing: pathogenic mutation in TTR (p.Val50Met). **Discussion:** Hereditary Transthyretin Amyloidosis (ATTRv) is an autosomal dominant disease typically presenting in adulthood with heterogeneous clinical manifestations, classically as a sensorimotor polyneuropathy, with early involvement of small fibers and significant autonomic dysfunction. There is a strong genotype-phenotype correlation with variable penetrance and age of onset with late-onset disease, typically over 50 years old, may present with a predominantly motor phenotype characterized by rapid progression and a worse prognosis. The phenotypic pattern mimicking motor neuron disease (MND), including tongue atrophy and fasciculations, has been documented in the literature. Based on the Gold Coast criteria, all these patients could potentially be misdiagnosed as having amyotrophic lateral sclerosis (ALS). **Final comments:** The predominantly motor clinical presentation in ATTRv patients with polyneuropathy is not commonly recognized by neurologists, leading to frequent misdiagnosis. We currently propose that ATTRv should be considered in the differential diagnosis of patients suspected of having ALS.

https://doi.org/10.5327/CBN240868

Hereditary transthyretin amyloidosis: a diagnostic challenge

Ana Luíza Xavier Drumond[1], Vivian Proença Lara[1], Gláucia Monteiro Oliveira[1], Igor Pereira Matos de Oliveira[1], Caio Cobucci Esteves[1], Fernando Augusto Bruzzi França[1], Thaís Ribeiro Oliveira Santos de Marcello[1], Gláucia Lara Resende[1], Cíntia Alvarenga Pereira Vieira[1]

[1]Santa Casa de Misericórdia de Belo Horizonte, Belo Horizonte MG, Brazil.

Correspondence: Ana Luíza Xavier Drumond; Email: analuizax95@gmail.com.

Case presentation: Man, 63 years old, previously healthy, retired. In August 2023, he was subjected to a surgical procedure for treating Carpal Tunnel syndrome. As per the standard procedure of the institution where the surgery was conducted, a fragment of the left wrist flexor retinaculum was submitted for histopathological examination, which revealed fibrosis and amyloid deposits. Due to these results, we requested a Transthyretin (TTR) Gene molecular analysis, which detected a pathogenic variant c.424G>Ap. VAl122IIe and a heterozygous mutation in exon 4 of the TTR gene. We postulated the hypothesis of Hereditary Transthyretin Amyloidosis and decided to perform more tests to investigate the possibility of involvement of other organs. According to the electrocardiogram, the patient had already developed first-degree atrioventricular block and nonspecific ventricular repolarization abnormality in the inferior wall. To complement the cardiological propedeutics, we conducted an echocardiogram which revealed atrium enlargement, signs of moderate concentric hypertrophy and grade II left ventricular dysfunction. Furthermore, some laboratory results were also abnormal, such as elevated proBNP levels and reduced glomerular filtration rate. Finally, to investigate the involvement of peripheral nerves, we performed an electroneuromyography of the lower limbs, which demonstrated to be compatible with symmetric axonal sensory polyneuropathy, with mild intensity. After initial propedeutics, we referred the patient to a specialist service for neuromuscular diseases and cardiology, for observing and treating the diagnosed disease. In May 2024, he began the use of the standard medication to treat amyloidosis, Tafamidis Meglumine, 20 mg per day. **Discussion:** Hereditary transthyretin amyloidosis is an autosomal dominant disease caused by a hereditary gene responsible for encoding the mutant form of the TTR protein. Mutation of this protein results in systemic amyloid deposits, and its accumulation occurs mainly in peripheral nerves and in the heart. This is a systemic and consumptive condition that begins in adulthood. Autonomic sensorimotor polyneuropathy is its primary feature. In many cases, Carpal Tunnel syndrome is a common neuropathic manifestation that appears as first symptom of the disease. **Final comments:** To encourage physicians to begin investigating the disease earlier, it is indispensable the conduction of further research to determine symptoms and their prevalence as an initial manifestation of amyloidosis, such as Carpal Tunnel syndrome, since early diagnosis allows for faster treatment and prevention of serious complications.

Correspondence: Mariana Teixeira Mesquita; Email: maritmesquita@gmail.com.

Background: Herpes zoster (HZ) is a chronic disease secondary to the reactivation of the varicella virus. The incidence of HZ increases with age and factors such as immunosuppression, infections, stress, and advanced age. The disease presents various stages and manifestations, some of which show a higher risk of complications such as postherpetic neuralgia, renal and gastrointestinal complications, and vasculitis. Currently, published data on clinical characteristics, severity, and outcomes related to HZ are limited. Understanding these data could potentially increase the impact of HZ management in Brazil. **Objective:** To identify and analyze the epidemiological profile of hospitalizations and deaths due to HZ in regions of Brazil, from 2019 to 2023. **Methods:** This is a descriptive study, with a quantitative approach, of a retrospective nature, regarding hospitalizations and deaths due to HZ in Brazil, between January 2019 and December 2023. The data were collected in April 2024 from the Hospital Information System of the Unified Health System (SIH/SUS), through the DATASUS platform. The selected variables were: processing year,

region/federal unit, age group, race/ethnicity and gender. **Results:** During the period from 2019 to 2023, Brazil registered a total of 20,164 hospitalizations due to herpes zoster. The Southeast region was the most affected, representing 45.5% of the total, with 9,190 cases, followed by the Northeast with 4,177 cases (20.7%), the South with 3,239 cases (16%), the Midwest with 1,876 cases (9.3%), and the North with 1,682 cases (8.3%). The year 2019 recorded the highest number of occurrences, with 5,631 cases, while 2021 had the lowest number, with 2,978 cases. As for age group, the most hospitalized population was those aged between 60 and 69 years, representing 14.5% of the total. The age group with the highest number of deaths was those aged 80 years or older, accounting for 39% of deaths. Regarding gender, females showed a slight predominance over males, with 50.3% of hospitalizations. In terms of ethnic characteristics, self-declared "pardos" (mixed race) were the most affected, representing 41.5% of hospitalizations. As for the total number of deaths, 1,505 cases were recorded, with the highest number also in 2019, with 407 deaths, and the lowest in 2021, with 261 deaths. **Conclusion:** HZ is associated with a significant risk of complications, including zoster-associated pain, impaired quality of life, and increased morbidity and mortality, especially for the elderly and immunocompromised individuals. The findings suggest a greater need for early intervention and prevention programs, such as vaccination, for the population aged 60 and over, women, those of mixed race, and residents in the Southeast region, in order to reduce complications associated with herpes zoster in Brazil.

Background: Herpetic encephalitis (HSVE) is a severe neurological emergency, representing 15 to 20% of sporadic encephalitis cases in adults, that can also affect children and neonates. The etiological agent is the Herpes Simplex Virus, primarily strains type 1 (HSV-1) and type 2 (HSV-2). Due to viral neurotropism, this condition can lead to cerebral complications, such as strokes, both in primary infection and reactivation after latency. The relationship between ischemic events and HSVE has been reported in several studies across different age groups and encephalic topographies. **Objective:** To analyze the manifestations and ischemic cerebral repercussions in patients with HSVE. **Methods:** This study is a systematic literature review based on articles published at PubMed, Biblioteca Virtual de Saúde (BVS), and SciELO databases. Publications from 2017 to 2024, in English and Portuguese, using the MeSH descriptors: "Encephalitis", "Herpes Simplex", and "Stroke", were considered. Analytical studies related to the theme, providing relevant information on herpetic encephalitis and its potential as a differential diagnosis for stroke, were included. Experience reports and studies not meeting the inclusion criteria were excluded. **Results:** The pathophysiological mechanism of the ischemic presentation of HSVE can be explained by the onset of large vessel vasculitis, leading to multifocal ischemia, which can mimic a stroke. Typical symptoms in this context include fever, chills, memory impairment, and mental confusion due to the involvement of the limbic system, which is common in HSVE. However, even in the absence of these symptoms, a differential diagnosis should be considered in young patients presenting to the emergency department with suspected stroke. Focal neurological deficit may also be present (26%), as well as speech disorders (57%), with receptive aphasia being the most common. Thus, early magnetic resonance imaging (MRI) is important, as atypical presentations are often misdiagnosed, which can delay the initiation of effective treatment or lead to inappropriate therapy. Findings from this exam usually include unilateral edema in the temporal lobe, generally sparing the basal ganglia. Additionally, cerebrospinal fluid (CSF) analysis can be requested, with the gold standard for diagnosis being the detection of viral DNA in the CSF. **Conclusion:** Therefore, the importance of correct diagnosis and management in patients with suspected stroke, especially if young, is evident, considering the differential diagnosis of the ischemic presentation of HSVE. In this context, the MRI and CSF analysis are valuable complementary exams for the exclusion or confirmation of this clinical condition. Thus, this text aims to draw attention to this pathology and expand knowledge in this still underreported area, to reduce its morbidity and mortality, as well as to prevent possible complications.

Heterozygous GRIN2B mutation as a cause of intellectual developmental disorder: a case report

Rodrigo Ibañez Tiago[1], Guilherme Augusto de Oliveira Soares[2], Isabela de Carvalho Florêncio[2], Rodolfo Antonio Corona[2], Renata Gratão Rezende[2], Carolina Cândida Vaz[2], Liane de Rosso Giuliani[2], Thiago Dias Fernandes[2]

[1]Universidade Federal de Mato Grosso do Sul, Faculdade de Medicina,
[2]Hospital Universitário Maria Aparecida Pedrossian

Correspondence: Rodrigo Ibañez Tiago; Email: rodrigoibaneztiago@gmail.com.

Case presentation: A 30-year-old male patient was referred to the neurogenetics clinic for evaluation of non-syndromic intellectual disability of unclear etiology. The patient was previously diagnosed with global developmental delay during childhood, with no further investigation conducted at that time. Early hypotonia was noted, though he could sit unsupported at 6 months of age. He ambulated with support at 2 years and 7 months, and independently at 3 years and 8 months. He developed cognitive deficits, requiring special education, and was eventually able to read and write with limitations. Physical examination revealed moderate intellectual disability, paratonia, and grade 3 tendon reflexes. The karyotype was 46 XY, with fragile X syndrome ruled out. Electroneuromyography and cranial MRI showed no abnormalities. Whole exome sequencing identified a de novo mutation in the GRIN2B gene at position chr12p13.611.817, with an A>G variation resulting in a missense mutation p.(Phe563Ser) in heterozygosity. The patient was diagnosed with autosomal dominant intellectual developmental disorder-6 with or without epilepsy (MRD6, OMIM# 613970). **Discussion:** A heterozygous mutation in the GRIN2B gene can lead to the phenotypes of both autosomal dominant intellectual developmental disorder-6 with or without seizures, and developmental and epileptic encephalopathy-27 (DEE27, OMIM# 616139). The GRIN2B gene encodes a subunit of the NMDA receptor, which is crucial for synaptic plasticity and neuronal development. Mutations in this gene can alter receptor function. In the present case, the de novo p.(Phe563Ser) mutation in the GRIN2B gene is consistent with the patient's intellectual developmental disorder. **Final comments:** This specific p.(Phe563Ser) variant in the GRIN2B gene has not been previously described in the literature. This case underscores the importance of detailed genetic investigation in patients with nonsyndromic intellectual developmental disorders. Identifying mutations contributes to a more precise diagnosis and informs management strategies, counseling, and prognosis for these patients.

Hidden focal cortical dysplasia in the frontal lobe: value of repeated mri correlated with electroclinical hypothesis

Fernanda Schuh Martins[1], William Alves Martins[1], Abner Cutrim[1], Vanessa Vargas[1], Fernanda Quadros[1], Eliseu Paglioli[1], Rafael Paglioli[1], Thomas Frigeri[1], André Luis Fernandes Palmini[1]

[1]Santa Casa de Misericórdia de Porto Alegre RS, Brazil.

Correspondence: Fernanda Schuh Martins; Email: fschuhmartins@gmail.com.

Focal cortical dysplasia (FCD) is the leading pathological cause of childhood epilepsy, particularly treatable through surgery in cases of frontal lobe epilepsy (FLE). According to Blumcke's 2011 classification, FCD is divided into three types: Type I, which appears in adults with mild symptoms and temporal lobe changes; Type II, found in children with extensive frontal lobe changes; and Type III, involving FCD with associated lesions like hippocampal sclerosis, tumors, or vascular malformations. FCD-related seizures are often resistant to medication, necessitating surgical intervention such as lesion resection, lobectomies, or hemispherectomies. **Case presentation:** B.P.H., a 6 year old girl with normal developmental presented with drug-resistant epilepsy starting at age five. Her initial seizures involved right ocular deviation, blinking, right cervical lateralization, and oral automatism lasting 10-15 seconds, occurring daily and increasing in frequency despite despite the use of different anti-seizure drug regimens. Physical examination showed no focal signs. The initial brain MRI was reported as normal, however, after a 48-hour vídeo-EEG analysis showing clear left frontal epileptiform activity, image review revealed thickening of the left frontal cortico-subcortical interface and an elongated image in the underlying white matter, suggesting FCD (previously unnoticed). After a clinical discussion, epilepsy surgery was performed on July 3, 2023, involving resection of the left frontal dysplastic area, resulting in complete seizure free. **Discussion:** The patient's history, physical examination, and diagnostic findings indicated FCD manifesting in school age with difficult-to-control seizures. MRI characteristics include cortical thickening, blurred white matter-gray matter junction, abnormal subcortical architecture, altered white matter signals, sulcal or gyral abnormalities, and segmental or lobar hypoplasia. This patient's MRI findings were, upon review of the imaging, consistent with FCD Type II. Literature suggests 60-80% of patients remain seizure-free post-surgery, aligning with this patient's outcome. The most favorable prognostic factor is total resection, defined as the removal of the MRI-visible lesion or the epileptogenic focus identified by intracranial EEG. **Final comments:** Despite advanced neuroimaging methods and effective surgical techniques, FCD remains underdiagnosed due to nonspecific EEG changes and difficulties in detecting FCD on standard MRI. Accurate diagnosis and surgical indication require tools like Vídeo-EEG and high-intensity 3T MRI with standardized epilepsy protocols. Considering FCD in cases of drug-resistant epilepsy with normal MRI findings is crucial. Further research on FCD epileptogenesis could lead to new pharmacological therapies, with advancements in medical technology providing hope for future solutions.

High values of glycated hemoglobin are associated with the severity of acute cerebral ischemia

Gabriele Babel[1], Thaís Janaína Crukil[1], Teresa Cristina Colvara Mattana[1], João Natel Pollonio Machado[1]

[1]Fundação Universidade Regional de Blumenau. Blumenau SC, Brazil.

Correspondence: Thaís Janaína Crukil; Email: thaiscrukil@gmail.com.

Background: Stroke is the second leading cause of mortality worldwide, affecting more than 100 million people annually. Diabetes mellitus (DM) is one of the main modifiable risk factors, increasing the risk of stroke by 2.5 to 3.6 times. The glycated hemoglobin test (HbA1c) is used as a control and diagnostic marker for DM, as its value reflects the average amount of glucose in hemoglobin over the last 120 days, eliminating the possibility of stress-induced hyperglycemia, which is common in cases of acute stroke. Few studies have explored the relationship between HbA1c levels and ischemic stroke (IS) severity, resulting in a limited understanding of this association. **Objective:** This study aims to evaluate the association between HbA1c values and the severity of acute IS, through a descriptive and retrospective observational study. **Methods:** The variables analyzed included age, sex, race, smoking, dyslipidemia, high blood pressure (HPB), DM and HbA1c values of patients with acute IS admitted to a tertiary hospital in Blumenau, between August 2023 and April 2024. It was approved by the Ethics Committee under opinion 6.633.545/2024. The Modified Rankin Scale and National Institutes of Health Stroke Scale were used to assess disability and severity, respectively. For statistical analysis, P-value <0.05 was considered. The sample consisted of 56 patients, with a mean age of 70.6±12.2 years, predominantly male, white, non-smokers, dyslipidemic, hypertensive, non-diabetic and normoglycemic. The multivariate logistic analysis indentified the following risk factors: age ≤60 years (P=0.02 OR: 8.152), HbA1c ≥7.0% (P=0.03 OR:6.862), hypertension (P=0.02 OR: 4.739) and dyslipidemia (P=0.12 OR: 4.147). DM was present in 39.3% of patients with IS but it was not statistically significant. **Results:** The results suggest that the diagnosis of DM had a smaller impact than having HbA1c ≥7.0%. It was observed that patients with HbA1c ≥7.0% werw more likely to be in groups with greater severity (HbA1c 9.29±1.81%) and disability (HbA1c 10.2±2.49%). Seven patients who were not diagnosed with DM had elevated HbA1c levels, and three had moderate/severe IS. It is important to include HbA1c in the IS care protocol, not only for diagnosing DM when there is hyperglycemia on admission but also for stratifying the risks of cardiovascular events. **Conclusion:** Our study highlighted that high levels of HbA1c were associated with greater severity and disability in IS, regardless of the previous diagnosis of DM. Patients with uncontrolled hyperglycemia had a 6 to 7 fold increased risk of moderate/severe IS. These findings suggest that HbA1c can serve as a prognostic marker to assess the severity of IS and diagnose DM.

High-resolution ultrasound in the diagnosis of ischemic neuropathy post-arteriovenous fistula surgery: a case report and review

Júlio César Iaia[1], Roberto Pereira Santos[1], Liene Duarte[1], Carolina Rouanet[1], Gustavo Honório[1], Celmir Vilaça[1], Marco Antônio Sales Dantas de Lima[1], Ana Lucia Zuma de Rosso[1], Rita de Cássia Leite Fernandes[1]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Júlio César Iaia; Email: julioiaiaufrj@gmail.com.

Case presentation: A 60-year-old female patient, hypertensive, dyslipidemic, and with chronic kidney disease (CKD), undergoing hemodialysis (HD) three times a week, had an arteriovenous fistula (AVF) created in the left upper limb. After 1 month and 20 days, she complained of pain in the operated limb, distal to the AVF. Physical examination revealed hypoesthesia, paresthesia, paresis, and burning pain in the left hand, in addition to a claw hand with more prominent paresis for flexion of the second and third digits, abduction and adduction of all digits, and wrist flexion. Other neurological aspects were normal. Electroneuromyography (ENMG) demonstrated reduced sensory and motor potentials of the left ulnar, median, and radial nerves. High-resolution ultrasound (HRUS), performed with a 12MHz linear transducer, showed an increased cross sectional area (CSA) of the left median and ulnar nerves. Compressive causes, such as compartment syndrome and nerve section, were excluded through magnetic resonance neurography (MRN). The diagnosis of ischemic mononeuropathy related to the AVF was established. Pain management with amitriptyline was effective. **Discussion:** The creation of AVF in these patients provides greater longevity and reducing the chances of infection in access management. However, ischemic neuropathy (IN) can arise as a complication, involving reduced distal arterial flow due to a steal from increased venous flow in the AVF, resulting in nerve ischemia. This condition is more frequent in women and diabetics. Symptoms of IN include pain, muscle weakness, and loss of sensation, often manifesting acutely. Differential diagnoses for these symptoms include steal syndrome from dialysis access (SSDA) and nerve compression by hematoma. For diagnosis, ENMG and MRN are commonly aplied methods. However, HRUS offers significant advantages such as greater accessibility, lower cost, painless and greater patient comfort. The use of HRUS in the diagnosis of IN is a new and promissing approach that has not been widely explored in the literature. HRUS has demonstrated high sensitivity and specificity in the evaluation of peripheral neuropathies, sugesting its potential as an effective and innovate diagnostic tool in this area. Although ENMG is accurate, combining HRUS with ENMG can enhance diagnostic accuracy. MRN, while useful for evaluating nerve diameter alterations and inflammatory aspects, faces limitations due to cost, availability, and the need for contrast. **Final comments:** To our knowlege, this is the first description of the role of HRUS in IN and compared do ENMG and neurography. HRUS proved to be a valuable tool in diagnosing IN post-AVF surgery for HD. This method is accessible, practical, and non-invasive, providing a viable alternative to traditional methods. This report highlights the need for further studies to better establish the accuracy of HRUS in this context and develop specific protocols for this condition.

Hirayama disease: a rare case report

Taianara Sampaio Reis[1], Amauri Pereira da Silva Filho[2], Melissa Fernandes Vilela de Freitas[3], Danielle Cortellazzi Colonna Romano[3], Gabriela Yumi Nakamura[3], Sabrina Borges Batista[3], Natália Rebeca Karpejany[1]

[1]Universidade Federal do Piauí, Teresina PI, Brazil. [2]Hospital de Emergência e Trauma Dom Luiz Gonzaga Fernandes, Campina Grande PB, Brazil. [3]Universidade Nove de Julho, São Paulo SP, Brazil.

Correspondence: Taianara Sampaio Reis; Email: taianarasampaio21@hotmail.com.

Case presentation: A 15-year-old female patient with no significant medical history, currently a student, born in Campina Grande and residing in Carurite, presented with a two-year history of progressive muscle weakness, atrophy, and tremors in her right hand since the age of 13. On physical examination, she was in good general condition with nothing relevant regarding other systems. Neurological examination revealed grade IV muscle strength, fasciculations, and significant atrophy in the right hand, with slight tremors at rest and with effort. The patient reported no improvement or worsening of symptoms over the two-year period. Electroneuromyography indicated an exclusively motor, axonal, multifocal, and asymmetric neuropathic process with signs of acute and chronic neurodegenerative changes in the C7, C8, and T1 myotomes. MRI of the cervical and dorsal spine revealed flattening of the anterior cervical spinal cord from C7 to T1. Based on clinical findings and diagnostic tests, the patient was diagnosed with Hirayama disease (HD). **Discussion:** HD also known as Juvenile Muscular Atrophy of the Distal Upper Extremity, is a rare motor neuron disease that affects the anterior spinal cord region spanning from segments C7 to T1 causing progressive muscle atrophy and weakness primarily affecting the unilateral hand and forearm, typically without sensory deficits. HD was first described in 1959, predominantly affecting asian young males. Several etiological factors have been associated with HD, including viral infections, spinal cord vascular insufficiency, high-impact physical activities, and focal spinal cord atrophy during cervical spine flexion. Electrophysiological and histopathological findings indicate a neurogenic disorder involving anterior horn cells and motor axons, resulting in characteristic signs of lower motor neuron impairment. Clinical diagnostic criteria for HD include weakness and atrophy of distal upper limb muscles, onset typically between ages 10 and 20, unilateral or predominantly asymmetric presentation, insidious onset with gradual progression and stabilization, absence of pyramidal signs or sensory disturbances, and exclusion of other differential diagnoses. **Final comments:** The management of HD typically involves conservative measures such as the use of a soft cervical collar and physiotherapy. Although rare, cervical spondylotic amyotrophy (CSA) should be considered in young patients presenting focal asymmetric atrophy of the upper limbs.

Correspondence: Leticia Bassani Devens; Email: leticiabassanidevens@gmail.com.

Background: Temporal lobe epilepsy due to hipocampal sclerosis (TLE/HS) is the most common type of focal epilepsy (1), and the most common cause of refractory epilepsy in adulthood. Alongside HS, MRI commonly reveals subtle alterations in the anterior temporal lobe white matter (aTLWM) of a significant part of TLE/HS patients, yet histopathological characterization of this abnormality has not been strictly studied. **Objective:** To analyze the histological characteristics of the increased T2 signal intensity (iT2SI) in the anterior temporal lobe white matter (aTLWM) in temporal lobe epilepsy due to hippocampal sclerosis (TLE/HS) patients. And to propose an immunohistochemical Photoshop-assisted method to quantify the proportional area of water content, expressed by vacuoles, in the aTLWM. **Methods:** Quantification of neuronal cells, astrocytes, oligodendrocytes and vacuolization in the white matter of surgical temporal lobe specimens was performed by immunohistochemical reaction (NeuN, GFAP, Olig2 and BMP, respectively). Surgical specimens from TLE/HS patients with iT2SI and normal T2 signal in the aTLWM were included for comparison. The histological samples were divided in three groups according the representativeness of the respective Magnetic Resonance location. G1 = representative

samples of iT2SI; G2 = samples from patients with normal T2 signal; and G3 = representative samples of areas with normal T2 signal in the aTLWM of TLE/HS patients with iT2SI. Clinical and demographic aspect were included in the analysis. **Results:** G1 samples showed larger proportional area of vacuolization than the other (p<0.001), but lower number of neurons (p=0,014). Patients with MRI positive for iT2SI presented younger age at surgery (p=0.018) and epilepsy onset (p=0.005). There was a tendency for right side occurrence of ETL/HS in iT2SI patients (p=0.069). **Conclusion:** The higher proportion of vacuoles in the representative samples of iT2SI could explain, at least in part, the histopathologic substrate of this signal alteration in the white matter of temporal lobe in patients with TLE/HS.

[3]Current Employee of Scholar Rock.

Correspondence: Ana Elisa Rodrigues Marangon; Email: elisarois@yahoo.com.br.

Background: Recent evidence has shown that many patients with ATTR amyloidosis develop a mixed phenotype of both polyneuropathy and cardiomyopathy, with polyneuropathy and musculoskeletal symptoms manifesting first, well before a confirmed diagnosis of cardiomyopathy. The **Objective:** To evaluate the occurrence of polyneuropathy and musculoskeletal manifestations prior to a confirmed diagnosis of ATTR amyloidosis with cardiomyopathy (ATTR-CM) in patients enrolled in APOLLO-B (NCT03997383). **Methods:** Baseline disease characteristics and medical history, coded using Medical Dictionary for Regulatory Activities (MedDRA version 23.0), collected during the screening period from APOLLO-B were analyzed in the overall study population and in patients by ATTR amyloidosis type (hATTR, wtATTR) across both treatment arms. The event prevalence and time from event onset to diagnosis of ATTR amyloidosis with cardiomyopathy were summarized descriptively. Additional analyses of polyneuropathy and musculoskeletal manifestations in a matched cohort of patients, as a comparator group, are ongoing. **Results:** Overall, medical histories of 359 ATTR-CM patients were analyzed, of which there were 72 hATTR and 287 wtATTR patients. Polyneuropathy and musculoskeletal manifestations were found in >20% and >60% of all patients, respectively, with these extra-cardiac events occurring at least 3 years prior to a confirmed diagnosis of ATTR-CM. **Conclusion:** This analysis demonstrates that polyneuropathy and musculoskeletal manifestations may be early signs that are potentially overlooked in patients with ATTR-CM. Multisystem clinical assessment and early identification of non-cardiac manifestations are therefore crucial for management of this debilitating condition.

HIV-associated neuromuscular weakness syndrome: report of two cases presenting with neuromuscular weakness associated with hyperlactatemia

Luiz Carlos Porcello Marrone[1], Renata Siciliani Scalco[1], William Alves Martins[1], Irênio Gomes da Silva[1], Cássia Elisa Marin Dapper[2], Jefferson Becker[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.
[2]Universidade de Caxias do Sul, Caxias do Sul RS, Brazil.

Correspondence: Cássia Elisa Marin Dapper; Email: cassiaemarin@gmail.com.

Case presentation: Case 1: A 30-year-old HIV-infected woman with a history of pulmonary tuberculosis presented to Hospital São Lucas with paresthesia and weakness in her lower limbs for 2 weeks. She had been on lamivudine, stavudine, and efavirenz for 10 months. Neurological examination showed grade 3 weakness in lower limbs and absent deep tendon reflexes. Her CD4 count was 229/mm^3, and viral load was undetectable. Within 10 days, symptoms progressed to lower and upper limbs, with lactic acidosis (up to 9.3 mmol/L) and autonomic dysfunction. Normal brain CT and CSF analysis, but nerve conduction studies indicated severe axonal sensorimotor polyneuropathy. HAART was discontinued, and she received ICU care with IVIG therapy. She developed respiratory failure, requiring mechanical ventilation and tracheostomy. Over 3 months, her symptoms improved, and she had only mild weakness and was discharged in with normal lactate levels. Case 2: A 44-year-old HIV-positive woman on stavudine, lamivudine, and efavirenz for 1 year was admitted with nausea, vomiting, stomachache, and diarrhea for 7 days. Her CD4 count was 130/mm^3. Initial evaluations were normal, but abdominal x-ray showed bowel distension. Surgical evaluation ruled out acute pathology, and endoscopy revealed duodenitis. After 10 days, she developed symmetric lower limb paresthesia and increased lactate levels (7.5mmol/L). Stavudine was discontinued, and riboflavin was started. Symptoms progressed to involve the upper limbs and cervical region, with hypotension and tachycardia. Lactate levels rose to 10.1 mmol/L, prompting ICU transfer. She developed respiratory failure with visual symptoms, tachypnea, and diaphoresis. Neurological exam showed generalized areflexia, ascending paresis, diplopia, and bitemporal hemianopsia. Mechanical ventilation was initiated, and IVIG commenced. Nerve conduction showed severe axonal sensorimotor polyneuropathy. She was discharged after 44 days without neurological deficits, continuing medication. Lactate levels normalized to 1.1 mmol/L. **Discussion:** HIV-associated neuromuscular weakness syndrome (HANWS) is a rare neuromuscular syndrome linked to hyperlactatemia and exposure to stavudine and/or didanosine. Severe hyperlactatemia and lactic acidosis are rare but serious complications of antiretroviral therapy, associated with dideoxynucleoside exposure, female gender, advanced immunosuppression, and possibly ethnicity. The pathogenesis of this neuromuscular syndrome in HIV-infected patients is likely multifactorial, involving mitochondrial and immunological mechanisms associated with both HIV infection and HAART. Treatment strategies for HANWS remain uncertain yet critical due to its potentially fatal nature. Most patients exhibit axonal alterations; however, the presence of demyelinating findings may guide therapeutic decisions, suggesting the possible use of intravenous immunoglobulin or plasmapheresis. Neurologists must maintain vigilance for diagnosing this syndrome promptly.

Home protocol proposal for increased activity in individuals after stroke based on specific and task-oriented motor training

Nicoly Alves Machado[1], Jayne Siqueira Cagliari[1], Marco Túlio Almeida Lenza[1], Luciane Aparecida Pascucci Sande de Souza[1], Gustavo José Luvizutto[1]

[1]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Nicoly Alves Machado; Email: nicolyamachado@gmail.com.

Background: Stroke is the leading cause of chronic disability in adults in Brazil. Therefore, it is necessary to institute increasingly early interventions aimed at preventing the onset of secondary complications and the development of compensatory movements. However, the lack of access to a specific motor training protocol in earlier stages can impair the level of motor recovery in individuals. **Objective:** To develop a guide for task-oriented and specific motor training in a home environment and to create a decision tree based on the levels of the Motor Assessment Scale (MAS) for clinical decision-making in patients in the subacute phase of stroke. **Methods:** This is a feasibility study for the development of a guide of task-oriented and specific exercises for the home environment that encompasses all domains of the core tasks and the creation of a decision tree following the levels of the Motor Assessment Scale (MAS) so that from the evaluation of patients, physiotherapists can choose the best exercises from the motor training guide based on the patient's level and to guide tasks based on mobility and motor impairment. **Results:** The primary outcome of this study was the production of a guide of task-oriented and specific exercises for the home environment, divided into the domains of core tasks with 20 exercises covering rolling (4 exercises), sitting (3 exercises), standing (3 exercises), walking (4 exercises), reaching and grasping (3 exercises), and grasping and manipulation (3 exercises). The decision tree for selecting the best exercise was based on the Motor Assessment Scale (MAS), divided into 8 items: 1- supine to lateral on the intact side; 2- supine to sitting on the side of the bed; 3- sitting balance; 4- sitting to standing; 5- walking; 6- upper limb function; 7- hand movements; and 8- advanced hand activities, with scores from 1 to 5 for classifying the level of mobility and motor impairment. Thus, at the end of the decision tree, we selected the most specific and efficient exercises for each level of mobility and motor impairment. **Conclusion:** We infer that the creation and dissemination of this guide of task-oriented and specific exercises for the home environment and the decision tree following the MAS motor levels to the community and physiotherapists is essential for professionals to have options in their clinical decision-making based on the mobility and motor impairment levels of their patients, and for the community to have an accessible, applicable, and cost-effective guide of task-oriented and specific exercises for the home environment to increase the level of activity post-stroke.

Hopkins syndrome, a breath of mystery: a case report

Antonio Edvan Camelo-Filho[1], Sabrina Soares Timbó[2], Amanda Camelo Paulino[2], Maria Luiza Miranda Carneiro[2], François Loiola Ponte de Souza[2]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.
[2]Hospital Infantil Albert Sabin, Fortaleza CE, Brazil.

Correspondence: Antonio Edvan Camelo Filho; Email: edvan.camelo@gmail.com.

Case presentation: A 2-year-old boy presented with progressive left leg weakness following a recent episode of an acute asthma exacerbation. The child had normal prior neuromuscular development and started walking around one year of age. His past medical history was significant for asthma, requiring hospitalization for an acute exacerbation five months before this evaluation. Two weeks after the asthma exacerbation, the patient developed weakness in his left leg, leaving him unable to stand or walk without assistance. He was initially diagnosed with hip synovitis and treated with non-steroidal anti-inflammatory drugs and physiotherapy. Due to a lack of improvement, he was referred to a pediatric reference center for further evaluation. Initial physical examination revealed left lower limb weakness, including hip flexion (MRC 2), ankle dorsiflexion (MRC 2), foot drop, and lateral rotation of the affected limb. This weakness was accompanied by

moderate limb atrophy and absent patellar and ankle reflexes. There were no fasciculations or sensory, cerebellar, or upper limb deficits. Electroneuromyography and muscle ultrasound confirmed a chronic asymmetric anterior horn cell disease with moderate left lumbosacral (L2-S2) compromise without acute ongoing denervation. Further investigations, including serology, spine MRI, and cerebrospinal fluid analysis, ruled out potential infections and compressive and inflammatory causes. The patient was, therefore, diagnosed with Hopkins syndrome. **Discussion:** Hopkins syndrome, characterized by poliomyelitis-like paralysis after an asthma episode, is a rare and challenging condition. This case highlights the differential diagnosis process, distinguishing Hopkins syndrome from other lower motor neuron syndromes. The temporal association between asthma exacerbation and paralysis and the clinical and electrophysiological findings were crucial in reaching the diagnosis. The exact mechanism linking asthma with amyotrophy remains elusive. Several hypotheses have been proposed, including nerve plexus damage from limb immobilization or intravenous cannulation, congestion of the brachial plexus due to severe dyspnea, and neurotoxicity or hypersensitivity reactions to medications. Typically, this condition develops within days to weeks after an acute asthma attack and is characterized by the sudden onset of flaccid paralysis affecting one or both limbs. This paralysis often progresses to severe muscle atrophy in the affected area. Corticosteroid treatment generally proves ineffective, and recurrences are uncommon. **Final comments:** This case emphasizes the importance of considering Hopkins syndrome in the differential diagnosis of any flaccid paralysis in children, particularly those with a history of asthma and asymmetric lower limb weakness. Early recognition and exclusion of differential diagnosis with an extensive investigation are vital for accurate diagnosis and appropriate management.

Case presentation: A 60y female with well-managed hypothyroidism, on a daily regimen of 50 mcg levothyroxine, underwent an elective arthroscopic repair for a traumatic rupture of the right rotator cuff. Anesthesia was administered intravenously, supplemented with an ultrasound-guided interscalene brachial plexus block using 20 ml of 0.3% ropivacaine (60mg). The procedure was initially uneventful. Postoperatively, the patient exhibited ipsilateral eyelid ptosis and miosis, but anhidrosis was not relevant. Notably, these symptoms of Horner's syndrome (HS) resolved spontaneously within 24 hours, without the need for further intervention. The patient was discharged without complications. **Discussion:** HS is a rare condition, characterized by the classic triad of ptosis, miosis/anisocoria, and anhidrosis affecting the ipsilateral face. This syndrome results from disruption of the oculosympathetic pathway and may arise due to iatrogenic causes, systemic diseases or traumatic injury. This case underscores the potential association between HS and interscalene brachial plexus block. The incidence of HS as a complication following an ultrasound-guided interscalene block with ropivacaine is approximately 9%. This adverse event occurs due to inadvertent diffusion of the local anesthetic to the cervical sympathetic chain, leading to a blockade of the ipsilateral stellate ganglion. **Final comments:** Despite its transient nature, HS may cause significant stress and discomfort to patients, particularly if they are not forewarned about this potential complication. It is imperative for clinicians, especially to neurologists, to recognize and appropriately manage this condition. Preoperative counseling regarding the possibility of HS should be considered to alleviate patient anxiety and enhance informed consent.

Hospital admissions and deaths due to Alzheimer's disease in Brazil: epidemiological analysis 2019-2023

Monyque Pinheiro Charchar[1] , Marcos Lude da Silva Ferreira[2], Alec Peixoto Rabelo[2], Edson Luis de Barros Siqueira[2], Luiz Carlos Figueiredo Filho[2], Luan Nascimento Pereira Amorim[2]

[1]Centro Universitário do Estado do Pará, Belém PA, Brazil.
[2]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Monyque Pinheiro Charchar; Email: mcharchar10@gmail.com.

Background: As life expectancy increases, certain diseases have become more prevalent in society. Notably, dementia, particularly Alzheimer's disease (AD), has become a significant concern. By 2020, the number of people living with dementia reached 50 million worldwide, making it a critical public health issue. **Methods:** This study is retrospective, descriptive, and quantitative in nature. Data on hospital admissions and deaths due to AD in Brazil over the last 5 years were analyzed. Variables such as regions, urgent cases, deaths, mortality rate, average annual stay, total cost, age group, gender, and race were examined. Data was obtained from the Hospital Information System of the Brazilian Unified Health System (SIH/SUS) between 2019 and 2023, publicly available via the SUS Information Technology Department (DATASUS) segment TABNET. **Results:** Between 2019 and 2023, Brazil recorded 7,866 hospital admissions due to AD, with 46.6% from the Southeast region and the highest rates in São Paulo (1,815). Rondônia, Pernambuco, Rio Grande do Sul, and the Federal District also had notable numbers, especially in 2023. Urgent admissions predominated in all states except Rio Grande do Norte and the Federal District, totaling 6,288, while elective admissions totaled 1,578. There were 1,905 deaths during this period, with 25.6% in 2023, and 58% in the Southeast region, which also had the highest mortality rate (30.08), peaking in São Paulo. The Midwest region had a significant mortality rate (28.02), especially in the Federal District. The average annual stay was 19.3 days, with higher values in the Southeast (25.4) and Northeast (21.4), particularly in Rio de Janeiro and Rio Grande do Norte. The total cost during the period was 12.3 million Brazilian reais, with the highest expenditure in 2023, representing 64.1% from the Southeast. The average expenditure was 1,565.97 Brazilian reais, peaking in 2020. The most affected age group was 80 years or older, accounting for 59.7% of cases and the highest death rate (1,338). Females were the most affected gender in all states except Piauí, representing 65.5% of cases and also had the highest death rate. The most affected races with the highest death rates were brown in the North, Northeast, and Midwest, and white in the South and Southeast. **Conclusion:** The analysis reveals a significant number of hospital admissions and deaths, especially in the Southeast region and São Paulo. Additionally, the highest expenditure was concentrated in this region, indicating a significant disparity in Brazil. The most affected age group is 80 years or older, which should be considered in health guidelines. Female gender, brown, and white race were identified as relevant risk factors for the disease. This survey is expected to aid in defining more efficient public health policies based on national reality.

Hospital admissions for migraine and other pain syndromes among children and teenagers in Brazil between 2018 and 2023: an analysis of DATASUS

Arthur Vinícius Feitosa Santos[1], Luana Cristina de Oliveira Lima[1], Vagner Costa da Cunha Júnior[1], Maria Cecília Leal Menezes[1], Sabrina Sthéphanie Ataíde Martins[1], Thiago Pariz da Silva Dumas[1], Arthur Aragão Nunes[1]

[1]Universidade Tiradentes, Aracaju SE, Brazil.

Correspondence: Arthur Vinicius Feitosa Santos; Email: arthur.vinicius04@souunit.com.br.

Background: Migraine is a neurological, chronic and multifactorial disease with genetic predisposition and association with environmental factors (poor quality of sleep, excessive use of caffeine, painkillers, fatty and spicy foods, etc.), hormonal, physical and mental factors. Its main characteristics are unilateral or bilateral throbbing headache, photosensitivity, nausea, vomiting, etc. **Objective:** To analyze hospitalizations for migraines and other headaches in Brazil and its regions during the period from January 2018 to December 2023. **Methods:** Descriptive epidemiological study using secondary data from the SUS Hospital Information System (SIH/SUS) Tabnet, being tabulated in Microsoft Excel, according to data collected from hospitalizations during the period from January 2018 to December 2023. The variables analyzed were federative region, gender, race/ethnicity and age group. **Results:** In the period analyzed, there were a total of 10,313 hospitalizations for migraines and other pains, of which 62.05% (6399 cases) affected females and 37.86% (3904) males. It is noteworthy that, from 0 to 9 years old, this disease had a similar prevalence between both sexes, however, from 10 to 19 years old there was a discrepancy of 1.96 times more for females (2448 hospitalizations), The age group that most contributed to this was 15 to 19 years old. It should be added that the regions with the highest prevalence were the Northeast (2079 hospitalizations) and the Southeast (2060). Regarding ethnicity, it was observed that 50.64% (5223) of the patients analyzed were black, 32.97% (3400) were white and 13.84% (1427) did not self-declare. **Conclusion:** Based on the results, it was found that hospitalization for migraine is more prevalent in the female population, especially those aged 15 to 19, demonstrating an association between this and hormonal factors, as menstrual irregularities, endometriosis, polycystic ovaries and hormone replacement, These may be factors that aggravate this pathology, making it more resistant and more frequent. Furthermore, these pains are more present in the Northeast and Southeast regions, which may correlate with the fact that the first is a place with high temperatures, leading to dehydration and changes in metabolism and, consequently, to crises while the second is marked by intense urbanization and exposure to photo-sound factors and stressors, which can contribute to the high prevalence of the disease. Therefore, the need to create public policies aimed at preventing and monitoring these headaches is evident in order to inform the population about the best control mechanisms.

Hospital admissions for viral encephalitis: a critical analysis

Felipe Andreani Camago Manduco[1], Bruna Andrello Lameira[1], Gabriel Felipe Lorençato[1], Manuela Silva da Costa[1], Mario Silva Jorge[1], Regina Salles Cauduro[1]

[1]Humanitas, São José dos Campos SP, Brazil.

Correspondence: Felipe Andreani Camargo Manduco; Email: felipemanduco1000@icloud.com.

Background: Encephalitis is an inflammatory process of the brain parenchyma that leads to brain dysfunction. It is usually an acute process, but it can be post-infectious encephalomyelitis, a chronic degenerative disease or a slowly progressing viral infection. Viral infections are the main causes of acute infectious encephalitis and the main viruses are: enterovirus, arbovirus and herpes virus. Although systemic viral infections by the etiological agents most implicated in their development are common, the occurrence of encephalitis is uncommon. Despite being relatively rare, it is a clinical condition that presents high rates of morbidity and mortality, especially when there is a delay in its recognition and management, giving it great epidemiological relevance. It manifests with a typical viral prodrome (fever, chills, myalgias) usually precedes brain involvement, ranging from subtle confusion to obtundation. **Objective:** Updated analysis of hospital admissions from the Basic Health Service (SUS) for viral encephalitis in Brazil between 2008 and 2024. **Methods:** The research was based on information on hospital morbidity from the SUS present in the Ministry of Health database (Tabnet) referring to the numbers of hospitalizations related to viral encephalitis, related to Brazilian regions and age groups. In which, the data collected takes place between the years 2008 and until the first 3 months of 2024, and between the age group of 0 to 14 years old. **Results:** From 2008 to March 2024, viral encephalitis was responsible for 28,507 SUS hospital admissions, with a predominance in the age group between 0 and 14 years old, which corresponds to 44.14% of viral encephalitis admissions. From 2013 onwards, there was an increase in hospitalizations for viral encephalitis of 25%, compared to 2012, and with a concomitant increase in hospitalizations in the Northeast region, with an increase of 115% compared to the previous year. Therefore, it affects more children aged 1 to 9 years (28% of all hospitalizations), mainly in the Northeast and Southeast regions (amounting to approximately 61% in the same age group). Another detail consists of the national stabilization of hospitalizations from 2015 onwards, with a predominance in the Northeast and Southeast regions. However, there was a decrease of 30,6% of the hospitalizations in the year of 2020 and a small variation in 2021, compatible with the pandemic years of COVID, and returning in 2022 to the same stabilization of the last decade. **Conclusion:** We can conclude that there has been an increase in hospitalizations for viral encephalitis in the last decade, suggestive of an increase in case notifications, improvements in the quality of health services and epidemic outbreaks of arboviruses. In the years affected by COVID-19 (2020 and 2021), there was a decrease in numbers, although this was not known to be due to a decrease in registration or lower medical demand due to the isolation resulting from the pandemic.

Hospital costs associated with malignant brain neoplasms in Brazil: an analysis of the last 5 years

Italo Lafayette Silva[1], Lucas Roque Evangelista[1], Dayanne Garcia de Freitas[1], Renan de Holanda Alves[1], Nicolle Gabrielle Lima Silva[1], Henrique Katsumi Kawano[1], Gilberto de Paula Pinheiro Filho[1], Renato Vieira de Freitas Filho[1]

[1]Universidade Nove de Julho, São Paulo SP, Brazil.

Correspondence: Italo Lafayette Silva; Email: italolafayette@gmail.com.

Background: Malignant brain cancer is defined by abnormal and uncontrolled cell growth in brain tissue, which can invade the brain locally and potentially spread to other regions of the central nervous system and other organs through metastasis. This condition not only profoundly impacts the lives of affected individuals, but also represents a significant challenge for society. In this context, it is crucial to analyze the hospital costs associated with this disease. **Objective:** The purpose of this study is to comprehensively investigate hospital costs related to malignant neoplasms of the brain in Brazil over the last five years, assessing the progression of these costs, the states with the highest and lowest investments and analyzing regional variations. **Methods:** A descriptive and quantitative study was carried out for this study. The data was obtained from the SUS Hospital Information System (SIH/SUS), made available by the Department of Informatics of the Unified Health System (DATASUS). covering the period from 2019 to 2023. The variables analyzed were: geographic region, federation unit and total hospital expenditure. **Results:** In the last five years, hospital costs associated with malignant neoplasms of the encephalon in Brazil totaled R$195,471,785.44, representing an increase of 23.20% in the period from 2019 to 2023. São Paulo led the way with the highest accumulated expenditure of R$46,635,530.08, followed by Minas Gerais with R$ 22,336,829.92 and Bahia with R$ 11,266,907.39. On the other hand, Amapá had the lowest total expenditure, totaling R$ 128,888.09. Roraima stood out for the largest percentage increase in spending over these five years, growing 1248.24%, from R$ 7,709.19 in 2019 to R$ 103,938.96 in 2023. The highest annual spending averages were seen in São Paulo (R$ 9,327,106.02), Minas Gerais (R$ 4,467,365.98) and Bahia (R$ 2,253,381.48), while Sergipe (R$ 138,387.11), Roraima (R$ 42,421.83) and Amapá (R$ 25,777.62) recorded the lowest averages. The year 2023 saw the highest total disbursement, reaching R$45,022,615.79, while 2020 saw the lowest spending, with R$ 35,529,263.18. São Paulo recorded the highest spending by state and year in 2023, totaling R$ 10,233,749.95, while Roraima had the lowest spending in 2019, with R$ 7,709.19. The regional analysis revealed that the Southeast region led in terms of total accumulated, reaching R$ 108,489,020.68, while the North region had the lowest accumulated, totaling R$ 7,082,581.06. **Conclusion:** The study revealed a significant increase in spending. São Paulo led the way with the highest accumulated spending, while Amapá had the lowest total spending. Roraima stood out with a significant increase in costs, suggesting possible improvements in the early detection of the disease, greater access to specialized health services or even an increase in the number of diagnoses made. This suggests that further research is needed to understand the causes of this significant increase.

hospitalization due to alzheimer's disease in brazil between 2019 and 2023

Kaike Eduardo da Silva Loboi, Leonardo Bastos Santos[1], Felipe Moraes Costa[1], Ruan Pablo da Silva Gomes[1], Arley Nikson Oliveira Barreto[1], Marcus Paulo Oliveira Lopes[1], João Lucas Lalor Tavares[1], Leonardo Aguiar dos Santos[1], Arthur Moraes dos Santos[1], Flávio Lobo Altieri[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Marcus Paulo Oliveira Lopes; Email: marcus.polopes@aluno.uepa.br.

Background: Alzheimer's disease (AD) is a neurodegenerative disorder associated with aging, characterized by progressive and irreversible cognitive decline. AD manifests clinically with insidious impairment of higher intellectual function, memory, mood and behavior. As the disease progresses, individuals may experience aphasia and disorientation. Epidemiologically, AD predominantly affects individuals over 60 years old, with a higher prevalence among women. Hospitalizations often occur due to the advancing stages of the disease, highlighting its profound impact on patient health and wellbeing. **Objective:** Analyze the epidemiological profile of hospitalizations due to AD in Brazil from 2019 to 2023. **Methods:** This is a descriptive ecological study, using secondary data in the public domain, obtained from the Hospital Information System (SIH-SUS) in the database of the Information Technology Department of the Unified Health System (DATASUS). The variables analyzed were: number of hospitalizations, geographic region, sex, age, race, hospitalization time and financial expenses. Descriptive statistics were performed using absolute (n) and relative (%) frequencies. **Results:** There were 7867 cases of hospitalization due to AD notified during the proposed time period, with an average of 1573 cases per year and an increase from 1600 in 2019 to 2122 cases in 2023. In the distribution by region of the country, it was observed that approximately 46.7% (3673) occurred in the Southeast, 25.5% (2009) in the South, 17.8% (1398) in the Northeast, 6.5% (515) in the Midwest, and 3.4% (272) in the North. The population was majorly female, with 65.84% (5180) of cases, and just 34.16% male (2687). Regarding the age group, the most affected by AD were the ones between 60 and 69 years of age, with 9.05% (712), 70 and 79 years, with 27.9% (2195) and 80 or plus years, with 59.73% (4699). As to race, the most affected were white, with 50.56% (3978), and brown, with 26.42% (2079). The average stay of hospitalization was 19.6 days, with direct healthcare expenses of R$ 2.463.649,8/year. **Conclusion:** Between 2019 and 2023, AD hospitalizations in Brazil grew significantly, with most cases occurring in the Southeast region and predominantly affecting females, whites, and individuals over 80 years old. Given the disabling and debilitating nature of this condition and the substantial public expenditure on its treatment, it is essential to understand the epidemiology of the affected population to develop strategies that enhance their quality of life.

Hospitalization period in a stroke unit associated with worse functional outcome at 90 days: a cohort study in a reference hospital in Bahia

Gabriel Teles de Oliveira Piñeiro[1], Maria Eduarda Messias Vassoler[1], Gabriel Souza Medrado Nunes[1], Milena Fernandes de Oliveira[1], Luiz Paulo Oliveira Martins[1], Thaís Barbosa de Oliveira[1], João Pedro Fernandes Gonçalves[1], Pedro Antonio Pereira de Jesus[1]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.

Correspondence: Antonio Lázaro Santos Soares Junior; Email: antoniolssj@ufba.br.

Background: Hospitalization is known to be associated with worse outcomes. However, the correlation between hospitalization and functional outcome at 90 days is not well explored in many populations, including patients with acute neurological injuries. **Objective:** To understand the association between hospitalized duration and functional outcomes in acute stroke patients. **Methods:** This study enrolled patients with acute stroke admitted to a stroke unit at a referral hospital in Bahia, between July/2023 and March/2024. Clinical and epidemiological characteristics were extracted from patients' medical records or obtained through personal interviews. Infection was defined as the administration of antibiotics or documented infection noted in medical records. CAM-ICU was performed by trained researchers and used to assess delirium. The assessment of functional outcome and survival was performed using the modified Rankin Scale (mRS) validated for telephone interviews. Worst functional outcome was defined as an mRS greater than 2. The Mann-Whitney test was used in the univariate regression analyses and a multivariate analysis was made using logistic regression. For predictors in the multivariate analysis, previous studies by the same cohort were used. **Results:** The study comprised 153 patients, of whom 49% were female, with a mean age of 64.9±12.5 years. Within this cohort, 51.6% were mixed-race. Regarding comorbidities, 34.6% had diabetes, 80.4% had hypertension, and 29.4% had dyslipidemia. Among all patients, the median NIHSS at admission was 7 (IQR: 4-11). A total of 142 patients (92.8%) had ischemic strokes, and 90 patients (58.8%) underwent thrombolysis. Infection was diagnosed in 63 patients (41.2%). Hospitalization

had a median length of 7 days (IQR: 5-13). The median mRS at 90 days was 2 (IQR: 0-4), with a total of 8 deaths at this mark. Delirium occurred in 32 patients (20.9%) at least once during hospital stay. The univariate regression showed that hospitalization was associated with higher mRS at 90 days (p<0.001). In the multivariate analysis, adjusted for age, hypertension, delirium, thrombolysis, NIHSS, and infection, the length of hospital stay remained significant (p<0.05; OR 1.07: CI 1.01-1.15). **Conclusion:** In the present study, the length of stay was identified as an independent predictor of worse functional outcomes on the 90th day. However, further research is necessary to gain a deeper understanding of this association.

https://doi.org/10.5327/CBN240888

Hospitalizations for Alzheimer's disease in the southeast region of Brazil: an epidemiological study (2013-2023)

Italo Lafayette Silva[1], Lucas Roque Evangelista[1], Dayanne Garcia de Freitas[1], Nicolle Gabrielle Lima Silva[1], Gilberto de Paula Pinheiro Filho[1], Renato Vieira de Freitas Filho[1], Henrique Katsumi Kawano[1], Renan de Holanda Alves[1]

[1]Universidade Nove de Julho, São Paulo SP, Brazil.

Correspondence: Italo Lafayette Silva; Email: italolafayette@gmail.com.

Background: Alzheimer's disease (AD) is a progressive and fatal neurodegenerative disorder that not only has a profound impact on the individuals affected, but also has significant repercussions for their families and society in general. In this context, understanding the pattern of hospital admissions related to AD is extremely important. **Methods:** For this study, a cross-sectional, descriptive and quantitative epidemiological survey was conducted. Data on Alzheimer's-related hospitalizations in the Southeast region of Brazil, from January 2013 to December 2023, were collected using the SUS Hospital Morbidity Information System (SIH/SUS), provided by the Department of Informatics of the Unified Health System (DATASUS). The variables analyzed included aspects such as geographic region, gender, race, type of hospitalization (elective or urgent) and age group. **Objective:** To analyze temporal trends and understand the dynamics of Alzheimer's hospitalizations in the Southeast region of Brazil, providing fundamental scientific input for the development of effective strategies and interventions to tackle this increasingly prevalent neurodegenerative disease. **Results:** Over the last decade, the Southeast region of Brazil has witnessed a total of 8,717 hospitalizations for AD. São Paulo leads the way with 4,633 cases (53.17%), followed by Rio de Janeiro with 2,296 (26.34%), Minas Gerais with 1,458 (16.74%) and Espírito Santo with 330 (3.78%). This period saw a percentage increase of approximately 56% in total hospitalizations. In 2015, there was the highest annual peak, reaching 1,040 episodes, while 2020 marked the lowest number, with 566 hospitalizations, it should be noted that the COVID-19 pandemic may have significantly impacted this number. In terms of patient profile, women accounted for the majority of hospitalizations, with 66% of the total. As for ethnicity, white people were the most affected, accounting for 50.74%, followed by brown people (19.22%), black people (5.84%), yellow people (1.08%) and people with no information on race accounted for 23.12% of hospitalizations. In terms of age group, patients over 80 were the most frequently hospitalized, accounting for 5,225 cases (59.94%) over the decade. In the context of hospitalizations, emergency admissions predominated, accounting for 74.6% of the total (6,501 out of 8,717). Elective admissions accounted for the remaining 25.4% (2,216 out of 8,717). **Conclusion:** This study reveals that, in the Southeast region of Brazil, hospitalizations for Alzheimer's are predominantly for women, from São Paulo, of white ethnicity and aged over 80. The high proportion of emergency admissions underlines the urgent need for effective management strategies for this neurodegenerative disease. There has also been a significant 56% increase in hospitalizations over the last decade, indicating a growing need for resources and policies to address this health challenge.

https://doi.org/10.5327/CBN240889

Hospitalizations for multiple sclerosis in the Brazilian Northeast: an analysis of DATASUS

Maria Cecília Leal Menezes[1], Luana Cristina de Oliveira Lima[1], Arthur Vinícius Feitosa Santos[1], Vagner Costa da Cunha Júnior[1], Sabrina Sthéphanie Ataíde Martins[1]

[1]Universidade Tiradentes, Aracaju SE, Brazil.

Correspondence: Maria Cecília Leal Menezes; Email: maricecilm00@gmail.com.

Background: Multiple sclerosis (MS) is a demyelinating, autoimmune and chronic neurodegenerative disease, caused by inflammatory and degenerative mechanisms that compromise the neurons of the central nervous system. This health condition can cause difficulties in carrying out activities of daily living and impact the individual's quality of life. Despite MS affecting individuals of both sexes and all ages, there are higher rates of hospitalizations in females and adults. **Objective:** To characterize the profile, according to epidemiological indicators, of hospitalizations for MS in the Northeast in the period between January 2018 and March 2024. **Methods:** This is a study with a quantitative approach, conducted based on an analysis of the database of the Hospital Information System of the SUS (SIH/SUS) and the Brazilian Institute of Geography and Statistics (IBGE) regarding hospitalizations for MS in the Northeast Region of Brazil. Information was collected on the patients' age group, gender, year of hospitalization and federation unit. The quantitative data were organized in a spreadsheet using the Microsoft Excel program. **Results:** The sample studied consisted of 2,941 hospitalizations for MS, with a high prevalence in adults between 30 and 39 years old (29.4%). In relation to Brazilian states, the highest number of cases (847) and numbers per 100,000 residents (38.3) occurred in Sergipe, with emphasis on hospitalizations in the age group between 30 and 39 years old. Furthermore, the Northeast state with the lowest admissions was Alagoas (31), which also had the lowest number of cases per 100,000 inhabitants (0.9). Even more, there was a high number of hospitalizations in women throughout the Northeast (70.5%), especially in Sergipe (655 patients). When analyzing ethnicity, brown color reached a percentile of 59.9% (1,764 hospitalizations) and black color reached 1.6% (49). An 80.08-fold increase in total cases was also observed in 2023 compared to 2017. **Conclusion:** Based on the results, it was found that hospitalizations for MS are more prevalent in women, both in the Northeast region in general, as in Sergipe. Moreover, a majority of admissions were found in adults aged 30 to 39 years, in the mixed-race population and in the state of Sergipe. Therefore, racial, geographic, age factors and the gender of patients were suggested in order to justify the distribution of multiple sclerosis in the Northeast so that effective public policies can be created aimed at preventing the pathology, ensuring better control of it.

[6]Universidad de Aquino Bolivia, Santa Cruz de La Sierra, Bolivia.
[7]Centro Universitário de Patos de Minas, Patos de Minas MG, Brazil.
[8]Universidade Estadual do Ceará, Fortaleza CE, Brazil.

Correspondence: Ana Clara Lacerda Freitas; Email: anaclf15@yahoo.com.br.

Background: Neurotic disorders, stress-related conditions, and somatoform disorders represent a broad spectrum of conditions that significantly affect individuals' mental health and quality of life. These disorders, often underdiagnosed and undertreated, are characterized by a variety of symptoms ranging from excessive anxiety and fear to clinically unexplained physiological reactions. In 2020, the prevalence of Post-Traumatic Stress Disorder (PTSD) in Brazil was approximately 8.5% of the population. **Objective:** To analyze the profile of hospitalizations due to neurotic, stress-related, and somatoform disorders across Brazilian states over the past five years. **Methods:** This ecological, cross-sectional time-series study was conducted using data provided by the Hospital Information System of the Brazilian Unified Health System (SIH/SUS) from 2019 to 2023. The variables considered included hospitalizations by demographic region, sex, age group, and race. Data collection and analysis were performed in June 2024. **Results:** There was a notable 37.5% increase in the number of hospitalizations by the public health network from 2019 to 2023, reaching approximately 4,128 hospitalizations in the last year analyzed. The Southeast region had the highest number of cases compared to other regions, while the North region had the lowest number of cases throughout the years analyzed. Regarding sex, there was a higher prevalence of cases among females, with approximately 10,206 (65.8%) cases, compared to 5,297 (34.2%) cases among males. Additionally, individuals aged 20 to 29 years and of white race were the most affected by these disorders. **Conclusion:** There has been a significant increase in the number of hospitalizations over the analyzed years. It was observed that these disorders affect almost twice as many women compared to men. Therefore, the current challenge for the country is the prevention and treatment of these disorders, aiming for early diagnosis and appropriate therapy to ensure the mental and physical well-being of these patients, as well as their greater integration into society.

Hospitalizations for transient ischemic stroke in women under 60 in the period from 2020 to 2023: an analysis of risk factors and lifestyle habits of women in the pandemic and post-pandemic period

Paola Carolina Santos Foinkinos[1], Maria Eduarda da Silva Santos[1], Matheus Prado dos Santos[1], Suzana Gomes de Oliveira[1], Zulma Catarina dos Santos Silva[1], Matheus de Carvalho Alves[1], Louise Araújo Corrêa[1], Bruna Martyres Gueiros[1], Hellen Jost Evaldt[2], Larissa Ádila Desireé Vieira de Andrade Duarte[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.
[2]Universidade Federal do Paraná, Curitiba PR, Brazil.

Correspondence: Paola Carolina Santos Foinkinos; Email: paola.csfoinkinos@aluno.uepa.br.

Background: Transient ischemic strokes occur when there is an alteration in brain function caused by a temporary, short-term blockage of the blood supply to the brain. In this sense, there are intrinsic risk factors associated with this pathology, such as gender, age and family history, in which there is a prevalence of risk in women over 55 with a previous family history of stroke. There are also extrinsic factors such as smoking, systemic arterial hypertension, a sedentary lifestyle, type 2 diabetes mellitus, among others, which can be avoided. **Objective:** To identify and analyze data on hospital admissions for strokes between 2020 and 2023 in Brazil, correlating with risk factors and lifestyle habits of women under 60. **Methods:** An ecological study was carried out using secondary data from the SUS Hospital Information System (SIH/SUS), using code G.45 of the ICD10 classification. From the search, information was collected and analyzed on hospital admissions for Transient Ischemic Stroke and Related Syndromes according to the variables regions of Brazil, age group, sex and period: women aged 20 to 59, in the historical series from 2020 to 2023 in the North, Northeast, Midwest, South and Southeast regions. **Results:** Between 2020 and 2023, a total of 10,727 hospital admissions of women aged 20 to 59 due to transient ischemic stroke and related syndromes were recorded in the sum of all regions of Brazil. Among these, the region with the highest prevalence of hospitalizations is the Southeast (4,322), followed by the South, Northeast, North and Midwest, respectively. In addition, there has been an increase over the years, with a total of 2,206 hospitalizations in 2020 and 2,964 in 2023, an increase of approximately 35% when comparing the pandemic (2020/2021/2022) and post-pandemic (2023) periods. **Conclusion:** Therefore, based on the data analyzed, it can be concluded that the Southeast and Midwest regions stand out on the national scene as the regions with the highest and lowest prevalence of hospitalizations, respectively. In addition, the 35% increase recorded between the pandemic and post-pandemic periods is relevant in the analysis carried out. Thus, the data collected reinforces that the pandemic context has had an impact on the lifestyle habits of women under 60 years of age, increasing the risk factors for developing strokes and their clinical complications, thus having implications for hospitalizations for cerebrovascular diseases in Brazil.

Hospitalizations for viral encephalitis in the northern region of Brazil in the pre-pandemic and pandemic period (2016-2019/2020-2023)

Erminiana Damiani de Mendonça[1], Maria Eduarda Tinti[1], Antônio Marcos Rabelo Barbosa[1], Ruth Léia Souza Alves Gomes[1], Guilherme Magalhães Rezende[1], Guilherme Reis Silva[1]

[1]Universidade Federal do Tocantins, Palmas TO, Brazil.

Correspondence: Erminiana Damiani de Mendonça; Email: erminiana@mail.uft.edu.br.

Background: Viral encephalitis is a condition characterized by inflammation of the brain parenchyma tissue, triggered by a viral infection. In addition to severe neurological impairment, patients often present symptoms such as fever, headache, seizures and altered level of consciousness, and some viruses may be associated with high mortality rates. Geographical distribution plays a crucial role in the spread of viral agents, along with seasonal variations and the individual's immune status. In Brazil, this disease is responsible for high hospitalization rates, emerging as a public health challenge. **Objective:** To identify and quantitatively evaluate the presence of viral encephalitis in the north of the country, based on the number of hospitalizations and the mortality rate of this disease during the pre-pandemic and pandemic periods. **Methods:** This is a quantitative and descriptive study based on data collected from the Hospital Information System of the Unified Health Service (SIH/SUS). Data was collected on the number of hospitalizations and the mortality rate due to viral encephalitis in the federal units of northern Brazil, evaluating age, gender and ethnicity as the main variables. Data collection was limited to the period from 2016 to 2023. **Results:** Between 2016 and 2019, there was a growing increase in the number of cases, with a total of 201 cases in 2019. However, there was a reduction of 11.94% and 16.38% in the number of cases in 2020 and 2021 across the Northern region, respectively, compared to the previous year. From 2022 onwards, the number of cases increased again, with values similar to the pre-pandemic period. The states of Amazonas and Pará led the number of cases throughout the period analyzed. The epidemiology of the affected population remained unchanged in 2020 and 2021, with only a quantitative reduction. Thus, children aged 1 to 4 years were among the most extensively affected age group. With regard to gender and ethnicity, there was a prevalence of male and eastern asian cases. The mortality rate was more prevalent among people aged 70-79. **Conclusion:** It can be concluded that the number of hospitalizations was higher in the pre-pandemic period. Amazonas and Pará led the way in the number of hospitalizations in both periods. In terms of deaths, Pará and Roraima stand out as the states with the highest incidence. In addition, there was a predominance of cases among males and people of asian ethnic and in the 1 to 4 year age group. Mortality rates were higher among the elderly. These findings emphasize the need for continuous monitoring and specific measures for vulnerable groups, as well as strengthening preventive and control strategies to protect susceptible populations.

Hospitalizations in Brazil due to schizophrenia spectrum disorder in childhood

Helena Rubini Nogueira[1], Helena Rubini Nogueira[1], Giovanna Ferraza Bragante[1], Luísa Montanini Baptista Nunes[1], Mariana de França[1], Milena de Lara Macedo[1], Natália Lima dos Santos[1]

[1]Universidade Municipal de São Caetano do Sul, São Caetano do Sul SP, Brazil.

Correspondence: Helena Rubini Nogueira; Email: helena.rnogueira@live.com.

Background: The pathophysiology of schizophrenia is based on neurochemical and anatomical alterations, as well as genetic and environmental aspects. When it starts early, the symptoms are considered to be non-specific, but the influence of traumatic events on its etiology is emphasized, resulting in the advent of psychic splitting as self-protection, although diagnosis at an earlier age is rare. Childhood schizophrenia is therefore considered to be when symptoms appear before the age of 13, with an estimated incidence of 0.1-1% before the age of 10 (a frequency 50 times lower than in those over 15). The treatments indicated in this scenario consist of typical and atypical antipsychotics, psychotherapy, electroconvulsive therapy (ECT) and transcranial magnetic stimulation (TMS). **Objective:** To characterize hospital admissions in the last 5 years of brazilian children with schizophrenia spectrum disorder by epidemiological variables. **Methods:** Descriptive analysis based on data obtained from DATASUS using the following variables: ICD 10 morbidity list (schizophrenia, schizotypal and delusional disorders); Age group (0-14 years); Brazilian regions; Sex; Color/race; Hospitalizations; Period (Jan/2019 to Dec/2023). **Results:** During the established period, 3.254 hospitalizations in children under 14 years were accounted for the morbidity. The Southeast region accounted for approximately 38% of this total (n=1.231), and the most prevalent age group was 10 to 14 years old (n=1.138). With regard to the sex affected, males were predominant in practically all age groups, except for those aged between 10 and 14, where around 5% more females were hospitalized. Similarly, females under the age of 14 accounted for the majority of hospitalizations in all Brazilian regions, except for the Northeast (where the male population was 2% higher). In addition, children aged 10 to 14 comprise the age group most vulnerable to hospital admissions for this neuropsychiatric condition (91%; n=2.980), with a predominance of individuals of brown color/race (n=1.165), who are also the majority of those affected in the Southeast (n=555). As for the cases that evolved to death, 1 outcome was recorded, corresponding to the Northeast region and to the age group of children under 1 year old. **Conclusion:** The data shows that the largest number of children diagnosed with schizophrenia spectrum disorders and that required hospitalization are between 10 and 14 years old, female, brown and live in the Southeast. The question remains that, in the area of child neuropsychiatry, diagnosis is a notable obstacle, even more so considering schizophrenia spectrum disorders.

Correspondence: Tainan Gomes Ferreira; Email: tainanferreira@uni9.edu.br.

Background: Stroke is a cerebrovascular disease characterized by the interruption of blood flow to the brain, caused by ischemia or hemorrhage.It is currently considered one of the leading causes of mortality in the country. Treatment often requires many strategies and a longer stay by care.The average cost per patient for any type of stroke in Brazilian public hospitals is approximately 9.670,00.Over the last 5 years, the average regional costs was divided into, North of 87.393.440,36, Northeast of 409.856.468, Southeast of 749.305.645,05, South of 336.790.531,65 and Central-West of 115.096.499,46. **Objective:** Temporal and geographic analysis of hospital costs for the treatment of non-specific stroke related to the average length of hospital stay. **Methods:** This is an original, descriptive, and cross-sectional study with data from Datasus, comparing the variables hospitalization authorization (HA), average length of stay, and value of hospital services by year of care according to all regions of Brazil between 2018 and 2023. **Results:** The year of 2018 had the lowest number of HA (n=13,613) and the lowest average length of stay (n=11.1), compared to 2019 that had an increase of 9.64%, duo to the higher number of hospitalizations (n=201,131).In 2020, there was a decrease of 0.25% in the total amount spent on lower HA(n=188,797) and in the average length of stay (n=7.3).However, in 2021 and 2022, both HA (n=200,265 and n=22,703) and the average length of stay(n=7.5 and n=7.8) increased, leading to an increase in the total amount spent by 7.69% and 30.7%, respectively.In 2023 there was a reduction in total spent, resulting in a lower HA(n=198,876) and average length of stay(n=7.5).Nonetheless, HA and the average length of stay were evaluated by region, North (n=61,743 and n=7.8), Central-west (n=60,924 and n=7.3), South(n=190,740 and n=6.9),Northeast (n=279,408 and n=7.8) and Southeast(n=432,570 and n=7.8). The average distribution of total expenditures by region, North 48.2%, Centra-West 13.51%, South 39.48%, Northeast 48.2% and Southeast 88.3%.The

Southeast had the highest number of HA and average total expenditures, while North and Northeast also showed higher expenditures compared to the other regions, which presented lower expenses. **Conclusion:** It is concluded that the years 2019, 2021 and 2022 presented higher hospital spending compared to the years 2018, 2020 and 2023 due to their higher number of HA and average length of stay for the treatment of non-specific stroke. When analyzed by region, the South had the lowest number of stays and the Central-West the lowest number of HA compared to the other regions.However, this did not represent the lowest expenditure, which was observed in the North region.The Southeast region had the highest HA and expenditures, with it is average length of stay being equal to or greater than the other regions.

Hsan type VII in a family from northeastern brazil

Mariana Alcântara Tavares[1], Lívio Leite Barros[1], Nayana Freire de Almeida Fontes[1], Leonardo Elias Araujo dos Santos[1], Francisco de Assis Aquino Gondim[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Mariana Alcântara Tavares; Email: marianaalcantara004@gmail.com.

Case presentation: In 2016, a 65 year-old man sought medical attention due to severe sensory loss in distal lower and upper extremities.According to him, it started back in his childhood, when working in plantations he would often get hurt without noticing, associated with pain and swelling in his wrists and ankles, which got gradually worse.He denied any comorbidities such as diabetes, but reported that his deceased father had a similar neurological condition and had been diagnosed with leprosy. He was admitted for diagnostic work-up that included a normal spinal tap, and a negative panel of autoimmune labs and leprosy screening. During his admission, his neurological exam revealed widespread areflexia with mild distal weakness and multiple finger and toe deformities due to repeated trauma and shortening of distal phalanges in all fingers, mallet finger deformity in both right hallux and right 2° toe, as well as in left hallux, plantar perforating disease in his left foot and ulcerations in his right hallux. An electromyography revealed a sensorimotor polyneuropathy with more severe sensory findings and some demyelinating motor features.The main diagnostic hypothesis became Hereditary Sensory and Autonomic Neuropathy. In 2019, genetic tests were done in order to determine a possible cause for his disease. A genetic panel for neuropathies revealed two uncertain significance mutations: a C>A variation in the gene SCN11A and a C>T variation in the gene SCN9A, both in heterozygosis, 1 copy of each. In the SCN11A gene, the variation happened in the chr3:38.926.843, causing the substitution of glutamine in the position 1000 for histidine, with poor preservation of position and surroundings in the different biological species and "in silico" predictors, demonstrating a potentially deleterious nature. In the SCN9A gene, a variation in the position chr2:167.133.677, promoted the substitution of cysteine in the position 886 for tyrosine, with great preservation of position and surroundings in the different biological species and "in silico" predictors, demonstrating a potentially deleterious nature. **Discussion:** In previous studies, SCN9A mutations have been associated with Congenital Insensitivity to Pain, when in autosomal recessive fashion. However, his heterozygous c.3000G>T - ENST00000302328 SCN11A mutation can potentially be the cause for his neurological findings in autosomal dominant fashion. **Final comments:** In cases with 2 reported variants, it is important to consider the genotype-phenotype correlation in order to make the final diagnosis. In this case, the presence of a single variant rules out the possibility of SCN9A related disease and suggests that HSAN type VII is the most likely etiology of his condition. Unfortunately, we were not able to test his deceased father in order to confirm the familial pattern, although the patient clearly reported a similar clinical course in his father. This study was authorized by the patient.

HSPB8-associated mutation resulting in myopathy with rigid spine with multiple muscle contractures and multiminicores in biopsy

Mayhara Rosany da Silva Santiago[1], Ana Caroline Paiva Simeão[1], Heloisy Maria Nunes Galvão[1], Raissa Josefa Pereira de Moura[1], Nereu Alves Lacerda[1], Heron Alves Vale[1], Natália Nunes Tenório[1], Maria Luisa Roberto Lima Lisboa[1], Ana Beatriz Roberto Lima Borba[1], Renata Amaral de Andrade Mendonça[1]

[1]Hospital Pelópidas Silveira, Recife PE, Brazil.

Correspondence: Mayhara Rosany da Silva Santiago; Email: santiago.mayhara@gmail.com.

Case presentation: A 15 years old boy presented with a history of proximal lower limb weakness over the last 2 years. He denied dysphagia, sphincter disorders or upper limb weakness. His prenatal, perinatal, and neuropsychomotor development were uneventful. There was no family history that resembled the patient's condition. Physical examination findings included severe proximal bilateral lower limb and axial weakness, with lumbar hyperlordosis, wingeds scapulas, and cervical hyperextension. There were also contractures that limited plantar dorsiflexion, torso and cervical anterior flexion, with a rigid spine predominant phenotype. Clinical examination was unremarkable. Due to the clinical phenotype an investigation of myopathies focusing on genetic causes was conducted. It showed moderate elevation of CK - 778U/L. Heart function evaluation was normal and Electroneuromyography was compatible with diffuse myopathy with proximal predominance. The forced vital capacity assessment revealed a moderate restrictive ventilatory disorder. Muscle biopsy revealed a myopathic pattern with minicores. Lower limb muscle MRI showed fat replacement of adductors, biceps femoris and soleus muscles. Genetic DNA ample panel found a possible pathogenic heterozygous mutation in the gene HSPB8. **Discussion:** Congenital myopathies are rare pathologies defined by genetic analysis, weakness pattern and histopathological findings. Other mutations in the HSPB8 gene were associated with CMT type 2, axial and distal adult onset myopathy, and, proximal limb-girdle rimmed vacuolar myopathy. This case reports a mutation of HSPB8 gene with a new phenotype correlated with a predominant axial myopathy beginning in second decade of life, resulting in a rigid spine and multiples muscles contractures atypical phenotype with minicores at muscle biopsy. **Final comments:** The full function of the HSPB8 gene is still unknown, but it appears to play a very important role to the normal neuromuscular physiology.

Correspondence: Anita Ferreira das Neves; Email: atinaneves@gmail.com.

Case presentation: A 29-year-old male was first admitted at age 24 with episodes of syncope, movement disorders, and psychomotor agitation, which had progressively worsened over the past three years. Examination revealed generalized involuntary tremors (rest and intention), bilateral Babinski sign, choreiform movements, plastic rigidity, dysarthria, generalized hyperreflexia, and psychiatric symptoms. His mother had a similar condition since the age of 26, without a confirmed diagnosis. Given the patient's clinical presentation and family history, the direct genetic test for Huntington's disease (HD) was conducted to detect the repeated cytosine-adenine-guanine (CAG) trinucleotide expansion in the HTT gene. The test revealed alleles 18 and 6 with 61 CAG repeats, indicating the patient is heterozygous with full penetrance. Cranial magnetic resonance imaging revealed a slight volumetric reduction in the brain and hippocampus, disproportionate to his age. Cranial computed tomography revealed marked reduction in the volume of the striatal bodies, especially on the left, and of the brain sulci and fissures, unusual for his age, without predominant lobar involvement. After confirming HD, treatment with levodopa and neuroleptics was started for symptomatic relief, although the response was minimal. His most recent hospitalization occurred a year ago for the treatment of acute chorea and the insertion of a gastrostomy tube due to severe oropharyngeal dysphagia, typical of neurodegeneration. Currently, the patient is on levodopa, alprazolam, biperiden, valproate, and haloperidol. **Discussion:** HD is an autosomal dominant neurodegenerative disorder characterized by an abnormal expansion of CAG repeats, which results in a defective huntingtin protein. This defective protein causes progressive neuronal degeneration, leading to a triad of motor, cognitive, and psychiatric manifestations. The age of onset of HD symptoms is inversely related to the number of CAG repeats; more repeats result in earlier symptoms. Most individuals with HD have between 40 and 50 CAG repeats, but our patient has alleles 18 and 6 with 61 repeats, explaining the early onset at age 24. Despite initial treatment with levodopa and neuroleptics, the patient's choreiform movements worsened. Additionally, the need for a gastrostomy a year ago due to severe oropharyngeal dysphagia, a common complication of HD, illustrates the complexity and progression of this disease. Although the patient's mother did not undergo confirmatory genetic testing, her symptoms, similar to those of her son, raise suspicion of HD due to its hereditary nature. **Final comments:** This case is notable for its diagnosis of a rare disease, particularly in a young individual, as HD is more prevalent between the ages of 40 and 50. Therefore, it emphasizes the importance of genetic testing when the triad of symptoms is identified, particularly if there is a suggestive family history.

Huntington's disease: a two-cases report of atypical presentations

Júlia Pio Fernandes Nery[1], Mariana Beber Chamon[1], Débora Palma Maia[1], Ricardo Oliveira Horta Maciel[1], Francisco Eduardo Costa Cardoso[1]

[1]Universidade Federal de Minas Gerais, Hospital das Clínicas, Belo Horizonte MG, Brazil.

Correspondence: Júlia Pio Fernandes Nery; Email: jupio0107@gmail.com.

Case presentation: The patients are two male brothers, ages 44 and 39 years old. They were referred to our clinic in 2023, being diagnosed as a fatherly-inherited Huntington's disease. The older brother reports a 12-year evolution of hyperkinetic movements, later characterized as chorea, a dystonic posture of the trunk, presence of rest and action myoclonus and cognitive decline. He still reports epilepsy, presenting with focal to bilateral tonic-clonic

seizures one year ago. The diagnosis was confirmed by genetic testing based on the presence of 18 and 45 CAG repetitions in the huntingtin gene (HTT). The younger brother presented 7 years ago with chorea, intentional tremor, generalized myoclonus, dysarthria and difficulty walking. Confirmatory genetic test has shown 18 and 44 CAG repetitions. Both patients have as the main symptom appendicular and axial myoclonus, spontaneous, stimulus sensitive, with postural and action stimulation, leading to great functional impairment. The older brother has laryngeal myoclonus. Their father had a similar clinical history, reported to have myoclonus and chorea, but he was never diagnosed, and couldn't be evaluated since he died at 45 years-old due to complications of the disease. Treatment was started with valproate, taking respectively 1,500 mg/day and 500mg/day, with partial improvement of the myoclonus, and control of the seizures in the epileptic patient. Association of benzodiazepines for both patients promoted greater relief of symptoms. **Discussion:** We presented two case reports of adult onset Huntington's disease with myoclonus as the main clinical feature. Myoclonus is rarely reported as a feature of adult onset Huntington's disease and is not a component of Unified Huntington's Disease Rating Scale (UHDRS), a commonly used scale for following up these patients. Proper diagnosis becomes challenging given this atypical presentation, and in other cases, could raise the possibility of an overlap of another disease. **Final comments:** Valproic acid and clonazepam were partially effective in controlling myoclonus. The knowledge about this atypical presentation of Huntington's disease helps in making the correct diagnosis, establishing an adequate symptomatic treatment and clarifying the prognosis to the patients and their families.

Huntington's disease mortality in Brazil: an epidemiological overview from 2013 to 2022

Guilherme Carvalho de Souza, Lívia Leite Goes Gitai[1], Alícia Eduarda Rios Soares[1], Antonia Cardoso Silva[1], Cecilia Maria Monteiro Barbosa[1], Eliab Batista Barros[1], Gabriela Barbosa de Sá Rocha[1], João Victor Vasconcelos Tavares Maximiliano[1], Julio César Soares Barros[1], Larissa da Silva Almeida[1]

[1]Universidade Federal de Alagoas, Faculdade de Medicina, Maceió AL, Brazil.

Correspondence: Guilherme Carvalho de Souza; Email: guicadesouza@gmail.com.

Background: Huntington's disease (HD) is a progressive neurodegenerative condition of autosomal dominant hereditary character, with varying phenotypic manifestations grouped into motor, cognitive, and psychiatric categories. The main symptoms are chorea, dystonia, incoordination, cognitive decline, and behavioral changes, typically beginning between 30 and 50 years of age, though they can occur earlier or later. **Objective:** To evaluate HD mortality in Brazil over the ten years from 2013 to 2022, using descriptive variables such as region, age group, and sex. **Methods:** The analysis was conducted based on a cross-sectional, retrospective, and descriptive epidemiological study using data from the Mortality Information System (SIM/DATASUS) for the period 2013-2022. Evaluating HD mortality, an analysis of the variables "Region," "Age Group," and "Sex" was performed. Population data for each region were obtained from the Brazilian Institute of Geography and Statistics (IBGE) and used to calculate mortality per million inhabitants of each region. **Results:** Between 2013 and 2022, a total of 1,310 HD-related deaths were recorded in Brazil. Of these, 47.63% occurred in the Southeast region, 24% in the South, 16.8% in the Northeast, 8.47% in the Central-West, and 3% in the North. However, when calculating mortality per million inhabitants, the highest rates were observed in the South (10.5 deaths per million inhabitants), followed by the Southeast (6.93), Central-West (6.52), Northeast (3.86), and North (2). Regarding age groups, individuals under 19 years old presented the lowest number of deaths during the period. From the age of 20, there is a gradual increase in mortality, reaching 279 deaths between 40 and 49 years old (21.3%) and peaking in the age group of 50 to 59 years old, with 381 deaths (29% of HD mortality). After this peak, a decline in mortality rates by age is observed, with the 60 to 69 age group accounting for 21.35% of deaths, followed by a further decrease in rates with advancing age. It is noteworthy that approximately 63% of deaths occurred in age groups under 60 years old. Regarding sex, the differences were not notable, with females accounting for 55% and males for 45% of the deaths. **Conclusion:** This study provides a deeper understanding of the various epidemiological aspects related to HD mortality. Regarding regional comparisons, the Southern region of Brazil stands out for its higher rates of HD mortality in relation to its population. As for the age at death, the fact that a large portion of deaths occurs before the age of 60 draws attention to the impact of HD on early life and raises questions about possible strategies needed to ensure support for patients with rare neurodegenerative diseases.

Hyperactivity symptoms are related to functional connectivity alterations in dopaminergic and noradrenergic networks in Alzheimer's disease

Fernanda Burle dos Santos Guimarães[1], Márcio Luiz Figueredo Balthazar[1], Brunno Machado de Campos[1], Rafael Brandes Lourenço[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Fernanda Burle dos Santos Guimarães; Email: fburle.psiq@gmail.com.

Background: Cholinergic, noradrenergic, and dopaminergic dysfunction play an important role in Alzheimer's disease (AD). The basal nucleus of Meynert (BNM), locus coeruleus (LC), and ventral tegmental area (VTA) are its prominent producer nuclei, respectively. Dysfunction of these nuclei seems to contribute significantly to the manifestation of neuropsychiatric symptoms (NPS). **Objective:** First, we aim to identify changes in the functional connectivity (FC) from NBM, LC, and VTA in patients with mild cognitive impairment (MCI) and dementia of AD, compared with healthy subjects (HS). Secondly, to verify potential correlations between the FC maps of these nuclei and NPS in MCI and mildAD patients. **Methods:** We analyzed data from 67 subjects over 50 years old. There were 18 HS and 49 subjects with altered amyloid-beta in the cerebrospinal fluid (25 MCI; 24 DA). Participants underwent rs-fMRI and completed neuropsychological evaluation, including the Neuropsychiatric Inventory (NPI). We compared FC differences among HS, MCI, and AD using ANCOVA test on individual FC maps for each seed region. We then correlated NPI syndromes (apathy, hyperactivity, affective syndrome, psychosis) scores with individual FC maps, adjusting for age and education (SPM12-toolbox). **Results:** In between-group analysis, regarding BNM, compared to HCs, patients with MCI showed significantly decreased FC in the left precentral gyrus and left anterior insula (volume 62.05 and 61.59 voxels, respectively). Similarly, AD patients, when compared to HCs, showed significantly decreased FC in the left and right medial precentral gyrus (volume 104.06 and 82.75 voxels, respectively) and in the right supramarginal gyrus (volume 64.68 voxels). Regarding the VTA network, unexpectedly, we found that, compared with MCIs, DA patients showed increased FC in the left central operculum (volume 92.29 voxels). No other between-group changes reached statistical significance for the LC. Considering the correlation of FC in AD patients and NPI, significant correlations were found exclusively with scores from hyperactivity subsyndrome (agitation, irritability, aberrant motor behavior, euphoria and disinhibition). Regarding right VTA, we noticed an increased FC mainly with the right and left subcallosal area (volumes 22.24 e 20.36 voxels, respectively) and left medial orbital gyrus (volume 26.46 voxels). We found a similar pattern in the left VTA and the right LC, showing increased FC predominantly with right subcallosal area (volumes 18.90 e 11.38 voxels, respectively) and left subcallosal area (volumes 13.84 e 12.19 voxels, respectively). When looking at BNM FC, no correlation reached statistical significance. **Conclusion:** Patients with altered amyloid-beta in CSF presented with decreased FC between precentral gyrus/insula and BNM. Also, the connectivity of noradrenergic and dopaminergic networks to the subcallosal area positively correlates to hyperactivity syndrome in AD.

https://doi.org/10.5327/CBN240901

Hypereosinophilic syndrome associated with polyneuropathy: a case report

Fabio Victor Vieira Rocha[1], Luísa D'Ávila camargo[1], Lucas Araujo Limongi horta[1], Lívia Valle Dos santos silveira[1], Renann Nunes Pirola[1]

[1]Universidade Federal do Espírito Santo, Vitória ES, Brazil.

Correspondence: Fabio Victor Vieira Rocha; Email: fabio.vvrocha@gmail.com.

Case presentation: 36-year-old man complaining of violet-colored edema in bilateral ankles and left hand, associated with restricted movement, pain and paresthesia. After 30 days, he developed bilateral and ascending paresis and paresthesia in the lower limbs, lymphadenopathy, and laboratory tests confirmed eosinophilia and an undetermined septic condition. After 7 days of ceftriaxone, his pain and edema improved. Electroneuromyography showed acute and subacute axonal and demyelinating sensory-motor polyneuropathy. On physical examination, he had dysarthria, right palatal drop, gait imbalance, globally abolished reflexes, decreased muscle strength (grades III and II), and compromised sensitivity. He denied fever and sphincter alteration. After using Pregabalin 300 mg/day and Prednisone 60 mg/day for 6 months, paresthesia and paresis improved, but eosinophilia persisted. **Discussion:** Idiopathic hypereosinophilic syndrome (HES) is a myeloproliferative disorder characterized by unexplained prolonged eosinophilia (>6 months) and specific organ damage. Diagnostic criteria for HES include sustained blood eosinophilia with at least 1,500 eosinophils/μL for more than 6 months, multi-organ involvement, and no other apparent causes of eosinophilia (e.g., parasitic, allergic). In this case, persistent eosinophilia and neurological involvement suggest HES, as other causes were excluded. Neurological manifestations, such as sensory-motor polyneuropathy, paresis, paresthesia, and abolished reflexes, are consistent with HES. Eosinophilia can damage peripheral nerves, contributing to the symptoms. Skin involvement is common in over 50% of HES patients, presenting as pruritic erythematous lesions, papules, nodules, and angioedematous and urticarial lesions, often associated with a better prognosis. Although this patient did not have significant cutaneous symptoms, lymphadenopathy and edema suggest systemic involvement. Thus, hypereosinophilic syndrome may result in a number of neurologic signs and multisystemic affect. Therefore, in cases of neurologic signs with no clinically established cause, especially in younger people, the possible HES should be considered. **Final comments:** This case illustrates the complexity of diagnosing and managing patients with eosinophilia and neurological involvement. HES should be considered in cases of prolonged eosinophilia with multi-organ involvement after excluding other causes. Management includes corticosteroids and other immunomodulatory therapies, with continuous monitoring of clinical and hematological response.

Hyper-religiousness as a clinical manifestation in Charles Bonnet's syndrome

Sephora Sabrina Candido de Almeida[1], Isabella Marranghello D'Amico[1], Yngrid Dieguez Ferreira[1], Rônney Pinto Lopes[1], Lunielle da Cruz Caldeira[1], Ricardo Salemi Riechelmann[1], Ana Carolina Gomes[1], Isabela Martins de Freitas[1], Alexandre Shoji[1], Diogo Haddad Santos[1]

[1]Irmandade Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Sephora Sabrina Candido de Almeida; Email: sephora_sabrina@yahoo.com.br.

Case presentation: We report the case of a black male 94-year-old patient who was a Catholic in childhood and converted to Spiritism in adulthood. He was a retired farmer and had studied to 1st grade. The patient was only able to see shadows for the past 5 years owing to bilateral cataracts. In the initial assessment, he showed partial orientation for time and space and actively complained of difficulties sleeping with vivid dreams. He also reported hallucinations which he recognized as unreal, but believed he experienced these because he was chosen to have them. These visions always appeared in a messianic context and associated with a religiously based discourse. He reported having medium abilities since the age of 15. His daughter reported good interaction with others and absence of social withdrawal. Family members complained of difficulties in the care process because, when challenged, he became aggressive. They also reported that the religious discourse continued throughout the day and night, hampering feeding and care during the night. The eye test revealed severely limited visual acuity bilaterally, and the patient was unable to count his fingers. He scored 15/30 points on the mini-mental state exame (MMSE). A non-contrast CT scan disclosed global atrophy without acute lesions. These hallucinations were typically worse at night and dark places, improving in brighter spaces. The ophthalmic evaluation indicated corrective bilateral cataract surgery, whereas heart surgery was contraindicated owing to high surgical risk. Atypical neuroleptics were prescribed at a low starting dose and progressive increased as required and according to results on reevaluation. Subsequent improvements in hallucinations (absence), sleep-wake cycle and functioning were reported. Family members cited that care provision was also easier. However, the family noted the patient had no further social contact, particularly at the Spiritist center, na activity which had hitherto had been a source of great pleasure. **Discussion:** Charles Bonnet syndrome (CBS) is a condition in which a visually-impaired individuals with intact cognition experience visual hallucinations in the absence of other sensory stimuli. The condition is generally associated with age-related macular degeneration (ARMD) and ocular diseases that affect central vision, most commonly cataracts, as occurred in the patient reported. These patients are often seen at centers for cognition because the manifestation of visual hallucinations in older persons is often confounded with the onset of early dementia syndromes. The pathogenesis of visual hallucinations remains unclear, although two main theories are accepted. The hypothesis of deafferentation suggests that loss of visual input changes synaptic function adjacent to the affected area, leading to increased excitability, manifesting as visual experiences in the absence of external stimuli.

Hypertrophic pachymeningitis secondary to granulomatosis with polyangiitis: case report

Stephania Neves Scapim[1], José Víctor Filho de Oliveira[1], Luiz Gustavo Chaves Gomes[1], Angélica Vilela Rodrigues de Alvarenga[1], Luiz Paulo Bastos Vasconcelos[1], Gustavo Guimarães Moreira Balbi[1]

[1]Universidade Federal de Juiz de Fora, Hospital Universitário, Juiz de Fora MG, Brazil.

Correspondence: Stephania Neves Scapim; Email: drastephanianeves@gmail.com.

Case presentation: A 53-year-old male, with a history of hypertension, obesity, and bilateral middle ear otitis complicated with chronic mastoiditis, developed a severe headache associated with fever and vomiting. He had a pattern of facial pain in bilateral nasal roots and persistent horizontal binocular diplopia, worsened on right gaze. He presented an episode of complete left-sided hemiparesis and dysarthria, spontaneously resolving within approximately 60 minutes. Initial hypothesis was mastoiditis complicated with meningoencephalitis, and he was treated with Ceftriaxone, Ampicillin, and Doxycycline. After hospital discharge, he experienced recurrence of the headache, associated with visual blurring and diplopia, leading to readmission. He underwent antibiotic therapy with Cefepime, Sulfamethoxazole, Trimethoprim, and Doxycycline, along with corticosteroid therapy with Dexamethasone. Mastoid computed tomography (CT) showed signs of bilateral chronic mastoiditis. Bilateral papilledema was observed on fundoscopy. Brain magnetic resonance angiography (MRA) revealed thickening and enhancement of the right cerebral convexity pachymeninges and interhemispheric falx, associated with subarachnoid hyperintensity on FLAIR sequence and areas of diffusion restriction, as well as signal changes in the right parietotemporal subcortical white matter, consistent with hypertrophic pachymeningitis (HP). Lumbar punctures showed increased opening pressure and ruled out fungal infections and tuberculosis (TB). Due to the hypothesis of an autoimmune disease, an evaluation by the Rheumatology team was performed, and the laboratory workup revealed a positive ANCA-c (1:40) by indirect immunofluorescence, with negative PR3-ANCA, MPO-ANCA, ANA, and RF. A hypothesis of granulomatosis with polyangiitis (GPA) was made. Due to dysphonia, videonasolaryngoscopy was performed to investigate subglottic stenosis, which revealed a vocal cords cyst, with no stenosis. Chest CT revealed a cavitated nodule in the apicoposterior segment of the left upper lobe. Bronchoscopy-guided bronchoalveolar lavage was negative for acid-fast bacilli microscopy and molecular TB testing. Given the diagnosis of severe GPA with meningeal involvement, IV pulse therapy with methylprednisolone and cyclophosphamide was prescribed, according to the CYCLOPS protocol. **Discussion:** HP is a rare condition characterized by inflammation of the dura mater, and GPA is among its etiologies. **Final comments:** The recognition of vasculitis as a cause of meningeal involvement resulting in HP should be part of the diagnostic consideration for clinical syndromes involving secondary headaches of non-infectious etiology, especially those associated with cranial nerve involvement and intracranial hypertension.

Hypocalcemia and functional outcomes in stroke patients post-thrombolysis

Antonio Lázaro Santos Soares Junior[1], Thaís Barbosa de Oliveira[1], Felipe Asaf Borges Millard[1], Julia Xavier Oliveira[1], Gabriel Souza Medrado Nunes[1], Pedro Antonio Pereira de Jesus[1]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.

Correspondence: Antonio Lázaro Santos Soares Junior; Email: antoniolssj@ufba.br.

Background: Thrombolysis is a widely recognized treatment for acute ischemic stroke. Despite its effectiveness, some factors have been associated with poorer outcomes following thrombolysis, such as advanced age and higher National Institutes of Health Stroke Scale (NIHSS) scores, however other factors have not been studied yet. Hypocalcemia is a common metabolic disturbance observed in various clinical settings. Its impact on patients undergoing thrombolysis for acute ischemic stroke remains underexplored. Understanding this relationship may enhance patient management strategies and improve prognostic assessments in acute stroke care. **Objective:** To address the association between hypocalcemia and functional outcomes in acute stroke patients post-thrombolysis. **Methods:** This study enrolled patients with acute stroke admitted to a referral hospital's stroke unit in Bahia, between July/2023 and March/2024. Clinical and epidemiological characteristics were extracted from patients' medical records or obtained through personal interviews. Hypocalcemia was defined as total serum calcium inferior to 8.5g/dL. The assessment of functional outcome and survival was performed using the modified Rankin Scale (mRS) validated for telephone interviews. Worst functional outcome was defined as an mRS greater than 2. For statistical purposes, numerical variables were expressed as mean or median, along with their standard deviation or interquartile range (IQR), while categorical variables are expressed as frequencies and percentages, when appropriate. Chi-square test was employed to compare the functional outcome and presence of hypocalcemia in admission. Logistic regression was used to adjust for age and NIHSS at admission. **Results:** Sixty-three participants were included, of whom 39 (61.9%) were male. The predominant color was brown, with 34 (54%) participants, followed by black (30.2%) and white (14.3%). The average age was 64.4 (±12.1) years. Regarding previous comorbidities, 21 (33.3%) individuals had diabetes mellitus, 48 (76.2%) had systemic arterial hypertension, and only 1 (1.6%) had chronic kidney disease. The mean NIHSS on admission was 10.6 (±5.3). At the time of admission, hypocalcemia was present in 13 (20.6%) participants. After 90 days post-stroke, 28 (44.4%) participants had worse functional outcomes. Hypocalcemia correlated with worse functional outcomes in the final model (B=1.35; CI: 1.01-14.71), with a p-value of 0.048. **Conclusion:** Hypocalcemia is correlated with worst functional outcomes 90 days after stroke in patients who underwent thrombolysis.

Hypoglossal nerve injury resulting from traumatic brain injury

Caroline Dresch Sabadin[1], Lara Auana da Rosa[1], Luisa Bianca Reis Parode[1], Lucas dos Santos Oliveira[1], Gabriel Santos de Almeida[1], Paulo Eduardo Mestrinelli Carrilho[1]

[1]Universidade Estadual do Oeste do Paraná, Cascavel PR, Brazil

Correspondence: Caroline Dresch Sabadin; Email: caroldsabadin@gmail.com.

Case presentation: A 22-year-old previously healthy woman was admitted to a University Hospital on July 2, 2022, due to a mild traumatic brain injury following a car accident. Upon admission, her ectoscopy and vital signs were unremarkable. Neurological physical examination showed isophoto-reactive pupils, preserved extrinsic ocular movement, a Glasgow Coma Scale (GCS) score of 14 (with a point loss in the best verbal response), and muscle strength of grade 5 in all limbs. On the same day, a contrast-enhanced cranial computed tomography (CT) scan revealed a slight obliteration of sulci and gyri, as well as occupied cisterns. The patient was admitted to the ICU for 6 days, and a new CT scan revealed a slight brainstem hemorrhage. She was discharged on July 11, 2022, and continued with outpatient follow-up by neurology. During outpatient follow-up, a cranial magnetic resonance imaging (MRI) showed sequelae changes in the subcortical white matter of the cerebral hemispheres, more evident in the frontal lobes, as well as hemosiderin degradation products in the left infratentorial cisterns. She presented with muscle strength of grade 5 in the upper limbs and left lower limb, and grade 4- in the right lower limb, with reduced thermal and pain sensitivity in the right hemibody. Cranial nerve evaluation revealed a deviation of the

tongue to the left. In a subsequent follow-up visit, there was partial improvement in hemiparetic symptoms on the left side of the body, but the tongue deviation to the left persisted, along with fasciculations in the tongue and hypoesthesia in the right hemiface. Regarding superficial reflexes, the plantar reflex was indifferent on the right and extended on the left. The patient continues to be followed up in the neurology outpatient clinic. **Discussion:** We describe a rare case of hypoglossal nerve palsy in a young patient following traumatic brain injury. The novelty of this case lies in its singularity: while most case reports document hypoglossal nerve injuries following high-impact trauma, typically associated with skull base fractures, this case highlights this complication occurring even in a trauma considered minor, without evidence of bone fracture. This underscores the importance of clinical vigilance in patients with traumatic brain injury. The rapid resolution of the patient's symptoms following steroid therapy and physical therapy suggests a good prognosis for isolated hypoglossal nerve injuries. **Final comments:** According to the literature, post-traumatic hypoglossal nerve palsy is rare. When it does occur, it is associated with high-impact trauma. Therefore, when this condition occurs in low-energy mechanisms, as in the described case, it is noteworthy. The reported case also emphasizes the importance of a complete neurological examination following trauma, as cranial nerve injuries can occur in isolation.

Hypoglossal paralysis secondary to paraganglioma in the right carotid bulb: a case report

Danielle Cleide da Silva Lima Queiroz[1], Pedro Jatobá Arteiro[2] , João Pedro Lopes da Silva Moraes[1], Gabriela Nogueira Couto[1], Bruno Ramos Levy[1], Amanda Sampaio de Sá[2], Álvaro José Porto Moreira[1]

[1]Real Hospital Português, Recife PE, Brazil.
[2]Universidade Federal de Pernambuco, Centro de Ciências Médicas, Recife PE, Brazil.

Correspondence: Pedro Jatobá Arteiro; Email: pedro.arteiro@ufpe.br.

Case presentation: We report a case of a 67-year-old woman, who presented with a sudden onset of dysarthria and occipital pressure, seeking neurological emergency services, being evaluated and seen, in addition to dysarthria, tongue deviation to the right with preserved trophy. The remainder of the neurological examination showed no changes, palate, uvula, gag reflex preserved, no changes on strength or sensitivity. A magnetic resonance imaging (MRI) was therefore performed, which revealed a solid formation measuring 3.8 x 3.5 x 2.2 cm, located superior to the right carotid bifurcation and posteriorly to the right internal carotid artery, with low signal on T1 sequence and heterogeneous high signal on T2 and FLAIR, and intense enhancement after contrast injection. Subsequently, the tumor was removed with anatomopathological and immunohistochemical analysis of the sample, which was positive for chromogramin, synaptophysin, CD34 and S100, negative for cytokeratin, Ki67 <1%. The radiological and histopathological findings are compatible with the diagnosis of paraganglioma. **Discussion:** Carotid body tumors (CBTs), also called paragangliomas, are rare neoplasms of the neuroectoderm, responsible for 0.6% of head and neck tumors and 0.03% of all tumors, with a risk of malignancy from 2% to 12.5%. The carotid body is the largest collection of paraganglia in the head and neck and is found on the medial aspect of the carotid bifurcation bilaterally, functioning as a chemoreceptor that helps in the autonomic control of blood pressure, heart rate and respiratory rate. CBTs are more frequent in elderly patients, between 50 and 70 years old, with a slight prevalence in females over males. CBTs are hypervascularized and slow-growing tumors, so that the majority presents as an asymptomatic neck mass, however in some cases there is compression or invasion of adjacent structures. Neurological deficits, such as the case reported, may occur in less than 10% of patients with CBTs, due to tumor compression of the sympathetic chain or adjacent cranial nerves, especially the glossopharyngeal, vagus and hypoglossal nerves. Radiological evaluation is necessary to establish the diagnosis of CBTs, with Doppler Ultrasonography, MRI, computed tomography (CT) and Angiography being the most commonly used. As in the case described, MRI shows high signal lesions on T2 sequence and low signal on T1, with enhancement after contrast injection. Biopsy is contraindicated in CBTs due to the high risk of complications due to the proximity of vascular structures. Treatment consists of surgical excision of the tumor, but radiotherapy can be performed in patients at high surgical risk or with extensive tumors. **Final comments:** CBTs are rare neuroendocrine tumors, often asymptomatic, but, as in the case described, they can cause neurological symptoms, due to compression of cranial nerves. Its diagnosis depends on imaging tests and its treatment is based on surgical resection.

Hypoglossal paresis in a relapse of multifocal acquired demyelinating sensory and motor neuropathy: a case report

Eduardo Mesquita de Souza[1], Matheus Alves da Silva[1], Rafael Bragança Rodrigues Matias[1], Ana Luiza Vieira de Faria[1], Amanda Miranda de Mendonça[1], Marcelo Freitas Schmidt[1], Fernanda Boldrini Assunção[1], Christiane Monteiro de Siqueira Campos[1], Alex Machado Baeta[1]

[1]Beneficencia Portuguesa de São Paulo, São Paulo SP, Brazil.

Correspondence: Eduardo Mesquita de Souza; Email: eduardoszmesquita@gmail.com.

Case presentation: A 53-year-old woman, with a nine-year history of Multifocal Acquired Demyelinating Sensory and Motor neuropathy (MADSAM), recently presented with paresis of the upper limbs and difficulty in tongue mobility. She had been in remission for two years following monthly immunoglobulin treatment. Neurological examination revealed loss of motor strength in the upper limbs, diffuse hyporeflexia, and left hypoglossal paresis. To investigate secondary causes, magnetic resonance imaging (MRI) and electromyography (EMG) of the tongue were performed, revealing reactivation of the underlying disease. **Discussion:** It's known that patients with MADSAM present with a markedly asymmetric, multifocal condition, sometimes indistinguishable from other forms of multiple mononeuropathy, resulting in diverse sensory and motor symptoms. Although evident manifestations of cranial nerve dysfunctions are rare in this condition, it is estimated that up to 5% of patients may present with cranial neuropathies, particularly in atypical forms. Most reports describe the involvement of the facial, trigeminal, and oculomotor nerves; however, hypoglossal nerve involvement, as in the presented case, is uncommon. Some patients in the spectrum of antibodies against nodal or paranodal proteins may present with combined central and peripheral demyelination, as well as cranial neuropathies. **Final comments:** The presented case highlights a rare and atypical manifestation of MADSAM with hypoglossal nerve involvement, evidencing the complexity and clinical variability of inflammatory neuropathies. Despite a two-year remission with immunoglobulin treatment, disease reactivation underscores the need for continuous vigilance and rigorous follow-up of these patients. This report reinforces the importance of considering the various clinical presentations of demyelinating neuropathies and the possibility of overlap with atypical clinical manifestations. The inclusion of hypoglossal nerve involvement expands the understanding of the extent and impact of cranial neuropathies in multifocal inflammatory conditions, emphasizing the need for comprehensive and personalized diagnostic approaches.

Hypokalemic periodic paralysis secondary to primary hyperaldosteronism: a case report

Eduardo Abrão Spínola Rezk[1], Natalia de Castro Fim Nakao[1], Yasmim Nadime Jose Frigo[1], Rebeca Aranha Barbosa Sousa[1], Gabriela Rossini Dantas[1], Itamar Meireles[1], José Eduardo Trentim Longo[1], Dominick Esthephanny Monteiro Silva[1], Hélio Aquaroni Farão Gomes[1], Ricardo Silva Carvalho[1]

[1]Universidade Estadual Paulista, Faculdade de Medicina de Botucatu, Botucatu SP, Brazil.

Correspondence: Eduardo Abrão Spínola Rezk; Email: eduardo.s.rezk@gmail.com.

Case presentation: Woman, 34 years old, hypertensive since the age of 30 with depressive disorder, presenting recurrent episodes of diffuse muscle weakness for four years associated with cramps. Initially, the episodes lasted an average of five days with spontaneous resolution, occurring semi-annually. However, over the last 6 months, they have been more frequent, lasting about 10 days each time. Initial evaluation revealed flaccid areflexic tetraparesis and severe hypokalemia (K= 1.8); correction of electrolyte imbalance was performed, and other causes were investigated. Routine electromyography of all 4 limbs showed no abnormalities; channelopathy protocol indicated increased amplitude from the start in short and long exercise tests, but without a pattern consistent with primary channelopathies. During investigation, an alteration in the aldosterone/renin activity ratio of 55 was found, and a nodule in the right adrenal gland on abdominal CT was consistent with aldosterone-producing macroadenoma. Thus, the hypothesis of secondary hypokalemic periodic paralysis due to primary hyperaldosteronism or Conn's syndrome was confirmed. Currently, the patient has suboptimal blood pressure control despite the use of four classes of antihypertensive medications, oral potassium supplementation, and is scheduled for adenoma surgery. There have been no recurrent neurological symptoms. **Discussion:** Episodic muscle weakness can be a clinical presentation of periodic paralysis, and there are known genetic causes for such conditions, such as primary hypokalemic periodic paralysis related to autosomal dominant genetic defects in voltage-gated calcium (type 1) and sodium (type 2) channels of the muscle cell membrane. There are also secondary forms of periodic paralysis described in the context of other conditions like thyrotoxicosis and adrenal diseases. Electromyography channelopathy protocols in these secondary cases may not exhibit a characteristic pattern. **Final comments:** It is important to consider secondary causes in the investigation of periodic paralysis, allowing for specific treatment and prevention of recurrence of neurological symptoms, as well as avoiding further complications from undiagnosed systemic diseases.

Hypothalamic atrophy and textural changes in polyglutamine ataxias

Marcondes Cavalcante Franca Junior[1], Livia Rodrigues[1], Thiago Junqueira R. Rezende[1], Alberto Rolim Muro Martinez[1], Breno Massurayama[2], José Luiz Pedroso[2], Orlando Graziani Póvoas Barsottini[2], Juan Eugenio Iglesias[3] , Simone Appenzeller[1], Letícia Rittner[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.
[2]Universidade Federal de São Paulo, São Paulo SP, Brazil.
[3]Harvard Medical School, Massachusetts, USA.

Correspondence: Marcondes Cavalcante França Jr.; Email: mcfrancajr@uol.com.br.

Background: Spinocerebellar ataxia (SCA) presents a complex genetic landscape, with over 40 subtypes. These autosomal dominant disorders manifest late onset and severe disability, primarily impacting the cerebellum but also involving other nervous system structures. **Objective:** While a single study has linked hypothalamus atrophy to SCA3, further research is needed to confirm and/or expand this association. **Methods:** The study involved 135 adult patients with confirmed SCA, including subtypes SCA1, SCA2, SCA3, and SCA6 and 117 controls. Image processing utilized H-SynEx for hypothalamus segmentation, delineating 10 distinct subregions. SynthSeg determined total intracranial volume. Analysis focused on hypothalamus subregion volumes and texture features derived from MR images. Non-parametric statistical analysis, included Mann-Whitney U tests with Bonferroni correction ($p<0.05$) and effect size calculation (AUROC). **Results:** The study findings reveal atrophy in various hypothalamic subregions in SCA1 and SCA3 when comparing with controls. Notably, the anterior inferior subregion was most affected, with AUROC values of 0.83 and 0.7 for SCA1 and SCA3, respectively. Texture analysis unveiled significant findings in SCA1 across all attributes and subregions, with AUROC values exceeding 0.8. Correlations were observed between volume and texture attributes and the SARA coefficient for SCA1, SCA3, and SCA6. Furthermore, significant associations were found between volume and texture attributes and the average time from ataxia onset for SCA1 and SCA3. **Conclusion:** This study reveals substantial atrophy in different hypothalamic subregions in SCA1 and SCA3, alongside texture differences in SCA1, SCA2, SCA3 and SCA6, even in areas without visible atrophy. These findings imply complex effects of ataxia on hypothalamic subregions, possibly preceding detectable clinical changes.

Hypothalamic dysfunctions in patients victims of traumatic brain injury: a systematic review

Laisy Bárbara Souza Silva[1], Danielli Regina da Silva[1], Airton Sena Oliveira Sales[1], Larissa Batista Xavier[1], Bárbara de Mello Galvani[1], Guilherme Victor Rocha Pereira[1], Lorenzo Pereira de Almeida Melo Montes[1], Emerson Oliveira Milhorin[1]

[1]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Laisy Bárbara Souza Silva; Email: d202010950@uftm.edu.br.

Background: Traumatic brain injuries (TBIs) can cause neuroendocrine dysfunctions, which are conditions that have not been extensively studied. Even milder traumas can result in pituitary hormone deficiencies, which may emerge with a certain delay after hypothalamic injury, with 70% of patients showing alterations within the first year of injury. Studies indicate that more than 30% of those affected by TBIs have dysfunction of at least one neuroendocrine hormone, with the combination of deficits being rarer. Hypothalamic injury leads to a diversity of clinical manifestations, given its crucial role in regulating various autonomic and endocrine functions in the body. Furthermore, late diagnoses lead to increased morbidity and mortality in these patients. **Objective:** To conduct a systematic review of studies concerning hypothalamic dysfunctions related to types of traumatic brain injuries. **Methods:** The data for this review were obtained from case studies through the PubMed and SciELO databases. The most prevalent type of injury based on the trauma mechanism and its consequences on the endocrine metabolism of the affected individuals were evaluated. Inclusion criteria were: studies published in the last 10 years, in English, and cases that necessarily presented traumatic injuries with endocrine repercussions after the event. **Results:** Titles and abstracts of 238 articles were analyzed from the search "hypothalamic dysfunction trauma case report," and 15 cases were selected for full analysis and reading. Excluded studies addressed hypothalamic dysfunctions resulting from pre-existing tumors, arteriovenous malformations, snake bites, surgical complications, spontaneous hemorrhages, and other non-traumatic causes. All the articles addressed were in English and published between 2015 and 2024. The sample population consisted of 9 adults (60%), 3 elderly (20%), and 3 children (20%). Regarding the trauma mechanism, 40% of the sample were injuries related to falls, 26.6% to sports injuries, and 20% to traffic accidents. Additionally, 2 studies mentioned injuries from firearm projectiles. Of the cases studied, 10 had a single hormonal deficiency. Furthermore, this evaluation found that 40% of cases had antidiuretic hormone depletion, 33% gonadotropic hormone deficiency, 33% adrenocorticotropic hormone deficiency, and 20% thyrotropic hormone deficiency. **Conclusion:** The scarcity of studies on the topic addressing the Brazilian situation of TBIs and their neuroendocrine repercussions demonstrates a significant gap in the national scientific literature, considering the high prevalence of TBIs in the country, both from traffic accidents and urban violence. The review thus highlights the need for the development of studies that investigate the understanding of TBI casuistry and clinical outcomes when the topic in question is neuroendocrine dysfunction.

Idiopathic hypertrophic cranial pachymeningitis: a journey from clinical presentation to histological diagnosis

Victor Garcia Ortiz[1], Glauco Cody Nagata[1], Caroline Schiochet Verza[1], William Alves Martins[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Victor Alfonso Garcia Ortiz; Email: victorgarcia.or@gmail.com.

Case presentation: A 49-year-old woman was referred to our tertiary hospital for progressive bilateral vision loss, ataxia and cognitive dysfunction. Past medical history revealed a hospitalization in 2004, with diplopia and dizziness, initially diagnosed as CNS toxoplasmosis. Viral serologies – including HIV – were all negative. In 2011, she began with prominent headaches, diplopia and visual loss. She was initially diagnosed with CNS tuberculosis, with slight improvement of symptoms with corticosteroids and tuberculostatics. However, symptoms reemerged and rendered her with bilateral vision loss. Soon after he had an episode of subacute upper right limb weakness, diagnosed as a ischemic stroke. At examination, she presented severe vision loss bilaterally, papilledema, ataxia and infrequent focal seizures. She was admitted for further investigation. Laboratory exams were unremarkable, except for an elevated protein in CSF. Serologies and PCR for multiple infections were all negative (including toxoplasmosis, mycobacterium tuberculosis, borrelia burgdorferi and others). MRI revealed enhancement and thickening of meninges, more preeminent at cerebral falx and tentorium. Also, cerebral edema and enlargement of cerebellum could be noticed. A biopsy of dura-mater showed fibrosis associated to hyalinization and lymphocyte inflammatory infiltrate. She was maintained on corticosteroids (dexamethasone) and initiated on azathioprine, with important improvement of symptoms. **Discussion:** Idiopathic hypertrophic cranial pachymeningitis (IHPM) is an extremely rare inflammatory illness, characterized by recurring cycles of inflammation and fibrosis in the meninges, leading to diffuse hardening and thickening of the dura-mater. First reported in 1869 by Charcot and Joffroy, initially attributed to syphilitic meningitis. Clinical manifestations are wide and include progressive headaches, multiple cranial nerve palsies, cerebellar dysfunction, seizures and myelopathy. Several rounds of inflammation and cicatrization lead to progressive fibrosis and thickening of pachymeninges (dura-mater). This progressive growth leads to compression of increased intracranial pressure, entrapment of cranial nerves and ultimately brain and cerebellar lesions. Soon in the course of this illness, MRI may point to diagnosis, as it shows impressive enlargement and enhancement of meninges, with a 'naïve' or aseptic CSF. Biopsy is the only way to ultimately confirm the diagnosis and must be done early, before irreversible damage has occurred, as in our patient. Recently, it has been shown that IHPM may be the CNS manifestation of IG4-related disease. Further studies may confirm this relationship. Nonetheless, treatment with immunosuppressants should not be delayed and must begin as soon as common infectious etiologies are excluded. IHPM is rare, under-diagnosed and potentially fatal illness. A high suspicion index must be alongside the neurologist, as treatment may avoid great disability

https://doi.org/10.5327/CBN240912

Idiopathic hypertrophic pachymeningitis: still a diagnostic challenge

Cândida Driemeyer[1], Ana Letícia Amorim de Albuquerque[2] , Vanessa Dantas de Andrade[1], Julia Santos Soares[1], Carlos Roberto de Mello Rieder[1], Arlete Hilbig[1]

[2]Santa Casa de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Cândida Driemeyer; Email: candidaplena@gmail.com.

Case presentation: A 47 year-old female presented to the emergency department with bilateral pulsatile headache and peripheral pattern palsy which began around 45 days ago but with acute worsening in the past 24 hours, when she also started with gaze paralysis. The patient initially visited an ophthalmologist, who ruled out acute ophthalmological complications and referred her to the emergency department. When the first symptoms started, the patient sought emergency care for the first time and was clinically diagnosed with Bell's Palsy secondary to herpes zoster infection and she was prescribed acyclovir 400mg 5 times a day and prednisone 60mg, both for 7 days with no improvement.The patient did not exhibit any skin lesions or vesicles. The patient had a history of systemic arterial hypertension and was taking continuous medication. On neurological examination at the arrival, the patient presented left hemiface infranuclear palsy, left eye ptosis, paralysis of all extrinsic muscles of the left eye and inability to perform convergence movement. The pupils and the right eye showed no abnormalities on physical examination. Magnetic resonance angiography showed pachymeningeal thickening on the left, especially frontoparietal and next to the ipsilateral cavernous sinus, with indeterminate findings. The patient underwent extensive clinical investigation: neoplasia screening and blood serologies were negative (HIV, VDRL, HbsAg, anti-HCV). Autoimmune investigation showed slightly elevated c4 complement (40, reference range 12-36) and no other alteration. Cerebrospinal fluid examination had high opening pressure (354 mmH2O), 1 cells/mm3, proteins 32mg/dL, glucose 71mg/d (blood glucose 106mg/dL). Cultures for bacteria and fungi, VDRL, and alcohol-acid-resistant bacilli were negative in CSF. PCR for herpes (HSV 1 and 2) and for tuberculosis was negative. Additional tests for cryptococcosis, proteinogram, and immunophenotyping were normal. Neoplastic cells were absent. She was then submitted to meningeal biopsy, which showed marked mononuclear infiltrate in areas, sometimes with perivascular arrangement, compatible with the diagnosis of Idiopathic Hypertrophic Pachymeningitis. **Discussion:** Headache improved in the first days of hospitalization with non-steroidal anti-inflammatory drugs. Given the lack of systemic disease findings, it was necessary to perform meningeal biopsy, it was followed by methylprednisolone 1g/day for 5 days, followed by corticoid weaning with progressive improvement of eye movement and facial palsy. Mainly differential diagnosis include nervous system infections, rheumatologic systemic diseases, neurosarcoidosis

and neoplastic lesions. Also, it is not possible to forgo biopsy due to the need to exclude IgG4-related disease. **Final comments:** This case demonstrates the need for attention to cases of headache with cranial nerve palsy. Despite current technology, a biopsy remains the only reliable method for excluding IgG4-related disease.

Case presentation: A 25-year-old female patient was referred due to reduced visual acuity in the left eye associated with ocular discomfort for two days. She reported a weight gain of 30kg over the past two years (33.2kg/m²). Ophthalmological examination revealed: corrected visual acuity in the right eye (RE) of 20/30 and left eye (LE) of 20/80, isochoric pupils, and a relative afferent pupillary defect in the left eye; biomicroscopy showed no abnormalities in both eyes (BE) and intraocular pressure of 12 mmHg (BE). Fundoscopy revealed papilledema in BE. Hematological tests and cranial magnetic resonance imaging (MRI) was within normal limits. Visual field (VF) testing showed reduced superior temporal sensitivity in RE and diffuse sensitivity reduction in LE. Optical coherence tomography (OCT) showed increased thickness of the nerve fiber layers and anterior displacement of the RPE-Bruch's membrane complex, suggestive of intracranial hypertension (IH). Cerebrospinal fluid analysis was unremarkable except for an opening pressure of 23 cmH2O (while on 1.5g of acetazolamide). After 45 days, the patient experienced worsening visual acuity in both eyes (RE 20/60 and LE) and VF. A new cranial MRI showed areas of hyperintensity in the frontoparietal region and spinal cord. In addition to the diagnosis of idiopathic IH, multiple sclerosis (MS) was suspected, and the patient underwent pulse therapy and immunosuppression. Improvement was noted in visual acuity (RE 20/25 and LE 20/60), as well as in VF, OCT, and MRI parameters during follow-up. **Discussion:** Idiopathic intracranial hypertension (IIH) typically presents in obese women of childbearing age and is associated with optic nerve changes, as observed in this case. The coexistence of IIH and MS, although rare, has been documented in the literature. Studies suggest that the chronic inflammation and autoimmunity underlying MS may predispose patients to increased intracranial pressure (ICP), resulting in overlapping conditions. The patient exhibited typical visual symptoms of IIH, such as papilledema and visual acuity loss, but the progression of symptoms and imaging findings raised suspicion of an additional underlying condition. MRI revealed demyelinating lesions characteristic of MS, supporting the diagnosis. **Final comments:** It is essential to be alert to signs of increased ICP in patients with MS due to the overlap of symptoms, which can complicate the diagnosis of MS. The coexistence of IIH and MS requires a meticulous diagnostic approach and careful therapeutic management. Effective management should include stringent control of ICP and appropriate immunomodulation for MS, aiming to preserve visual function and improve quality of life. This rare case highlights the importance of comprehensive differential diagnosis in patients with neuro-ophthalmological symptoms and emphasizes the need for continuous monitoring for associated complications.

Correspondence: Kevellyn Cruz Aguilera; Email: kevellynaguilera@hotmail.com.

Case presentation: We report a case of a female patient, 24 years old, who developed a pressure-type headache in the occipital region in November 2023 that worsened when lying down, associated with binocular diplopia and difficulty blinking to the right. On physical examination, abducent and facial nerve palsy was seen, in addition to bilateral papilledema. Brain magnetic resonance and brain magnetic ressonance angiography was perfomed, demonstrating an empty sella turcica and a lumbar puncture with an opening pressure of 44cmH2O, closing the diagnosis of idiopathic intracranial hypertension. **Discussion:** Idiopathic intracranial hypertension (IIH) is an entity still misunderstanding, in which there is an increase in intracranial pressure in the absence of a secondary condition, such as brain tumors or strokes, for example. It was characterized in criteria for the first time by Walter E. Dandy who listed 22 cases having similar symptoms and signs with increased intracranial pressure seen on lumbar puncture, with no determining factor for this, categorizing the main findings of this condition. These criteria were revised in 2013 by Friedman et al., listing six criteria necessary for the diagnosis, including: the presence of papilledema, without neuroimaging findings that could justify the increase in intracranial pressure, with the remainder of the neurological examination showing no changes, except for involvement of other cranial nerves and lumbar puncture with increased opening pressure (considering 25cmH2O in adults and 28cmH2O in children) with CSF analysis without changes, in addition to incorporating imaging findings in the absence of papilledema or involvement of the sixth pair of cranial nerve. The findings most related to IIH are: headache with characteristics similar to those observed in tension and migraine, bilateral papilledema, paresis of the sixth pair of cranial nerve - a finding that can lead to diplopia - and, sometimes, the presence of pulsatile tinnitus. There are also cases in which unusual symptoms occur, including paresis of other cranial nerves or unilateral papilledema, such as the one presented in the case above, with the presence of paresis of the seventh cranial nerve. When evaluating the concomitance of the facial nerve palsy and IIH, there are some points to be considered, considering that the anatomy of the facial nerve makes the compression process difficult, having a point of probable vulnerability in the intratemporal segment of the facial canal, which may represent a justification for the framework. Facial palsy tends to be unilateral and peripheral, generally associated with abducens nerve palsy. **Final comments:** There are few descriptions in this described clinical context, therefore, with the aim of promoting more about other presentations, the data presented in this case report is relevant.

Illiteracy and low education levels affect Parkinson's disease screening in an epidemiological study in the administrative region of candangolândia.

Deborah Almeida de Oliveira[1], Letícia Dias dos Santos Silva[1], Flávia Maria Campos de Abreu[2], Bárbara Querem Hapuque da Silva Linhares[2], Clarisse Santos Ferreira[1], Sabrina Simplício de Araújo Romero Ferrari[1], Simoneide Souza Titze de Almeida[1], Pedro Renato de Paula Brandão[3,4]

Correspondence: Deborah Almeida de Oliveira; Email: deborah.almeidadeoliveira@gmail.com.

Background: Parkinson's disease (PD) is a chronic, progressive neurodegenerative disorder characterized by motor and non-motor signs and symptoms. Due to the absence of a single definitive test for PD and the overlap of its signs with other health conditions, clinical evaluation is necessary. **Objective:** Identify potential challenges in the screening process due to low education or illiteracy in the studied population of Candangolândia - Federal District, Brazil, and demonstrate that the screening method aids in guiding the diagnosis. **Methods:** The present work is part of the PROBE-PD project (Prodromal and Overt Parkinson's Disease Epidemiological Study in Brazil - approved by the Research Ethics Committee of the Beneficent Society of Ladies Hospital Sírio-Libanês - CEPesq/HSL-5.482.147). The study population consists of individuals aged 60 years or older living in the administrative region of Candangolândia-DF. In the first stage of the study, a questionnaire is administered that includes nine yes-or-no questions and one single-response question from the REM Sleep Behavior Disorder Questionnaire (RBDQ1). Participants who answer 'yes' to two or more items from the Tanner Questionnaire or score for the RBDQ1 question proceed to the second stage of the study, which consists of a clinical evaluation by a neurologist specializing in movement disorders. **Results:** So far, 1253 participants have been screened, with 433 (34.6%) testing positive on the Tanner Questionnaire. In the second stage, a sociodemographic questionnaire was applied. The education levels are as follows: Specialization: 1.32%, Graduates: 3.31%, Incomplete higher education: 1.32%, Complete secondary education: 18.54%, Incomplete secondary education: 12.58%, Complete primary education: 15.23%, Incomplete primary education: 28.47%, Literate: 9.93%, Illiterate: 9.3%. It was observed that due to the varying comprehension skills related to low education levels, participants had difficulty understanding and responding to the stage I screening questionnaire. The questions that had the highest number of positive responses like changes in writing (13.7%), in voice (14.9%), freezing (12%), facial expression (10.1%), and gait (18.4%) required greater interpretative and comprehension abilities. The lack of familiarity with technical terms, despite facilitation by researchers, combined with low education levels, may have contributed to misunderstandings, leading to false positives. These are cases where results indicate the presence of the disease when they are not actually related to it. **Conclusion:** In a screening process, the level of education can affect responses, as some individuals may have difficulty understanding the questions. Therefore, it is important to consider these limitations and find ways to make the questions more accessible and understandable for all participants. This will also facilitate the screening process for the diagnosis of PD.

Imaging pattern in hypoglycemic encephalopathy: an important differential diagnosis to remember

Carolina Oldoni[1], Rhaná Carolina Santos[2], Victor Hugo Wilhelm Annes[2], Lorenzo Gabriel de Azevedo Viera[2], Enio Bonamigo Junior[3], Ana Letícia Amorim de Albuquerque[2]

[1]Hospital de Clínicas de Porto Alegre, Porto Alegre RS, Brazil.
[2]Universidade do Vale do Rio dos Sinos, São Leopoldo RS, Brazil.

[3]Digimax Medicina Diagnóstica, Pato Branco PR, Brazil.

Correspondence: Carolina Oldoni; Email: carololdoni15@gmail.com.

Case presentation: A 32-year-old male patient, obese, smoker, alcohol user, and with type 1 Diabetes Mellitus (DM) managed with NPH and regular insulin, presented to an emergency room with generalized tonic-clonic seizures (GTCS) after inadvertently taking extra doses of regular insulin. Upon arrival, he experienced new episodes of GTCS, and was diagnosed with Status Epilepticus (SE) in the context of hypoglycemia (capillary blood glucose=25). Hypoglycemia was corrected, empirical thiamine was started, and the SE medication management was guided by continuous electroencephalogram. Despite the primary cause being evident from the onset, given the refractoriness even with adequate glycemic management, cerebrospinal fluid investigation and cranial CT scan were performed, both normal. The patient was free of seizures after 24 hours and extubated within 3 days. He presented with severe comprehension aphasia. Contrast-enhanced cranial CT was repeated, showing bilateral and symmetrical cortical contrast enhancement in the temporo-parieto-occipital transition, right olfactory sulcus, and insula. Cranial MRI revealed scattered cortical enhancement segments bilaterally, predominantly in the temporal lobes and temporoparietal transition, also involving the right insula and right frontal lobe. T2/FLAIR hyperintensities were observed in the anterior portions of the hippocampi, as well as gadolinium enhancement areas in the hippocampi. On DWI b1000 scans, there were clear bilateral cortical hyperintensity, mainly temporal. A diagnosis of hypoglycemic encephalopathy (HE) was made with MRI and postictal findings. **Discussion:** Imaging changes in the postictal context are widely known and routine in neurology. However, MRI changes in hypoglycemic encephalopathy are not as frequently observed. Classically, there is involvement of the cerebral cortex (mainly parieto-occipital and insula), hippocampus, posterior limb of the internal capsule, and basal ganglia (when involved, associated with a worse prognosis), typically bilateral. The cerebellum, brainstem, and thalami are spared. It is considered that DWI/ADC shows the earliest and most sensitive changes, indicating diffusion restriction, which is often reversible. There is the presence of T2/FLAIR hyperintensity and T1 hypointensity. Corpus callosum (CC) involvement can occur, producing the so-called boomerang sign (cytotoxic edema in the splenium of the corpus callosum, typically seen in cytotoxic lesions of the CC). The gadolinium enhancement changes in this patient can be well explained by the postictal state. **Final comments:** This report highlights the imaging pattern shown on MRI of a patient with hypoglycemic encephalopathy, with the potential for prognostic information depending on the affected areas. Considering the imaging pattern alone, hypoxic-ischemic injury (which would involve the thalami) and Creutzfeldt-Jakob disease (different clinical presentation) are also admitted as differential diagnoses.

Imbalance in a 44-year-old woman with atrophy cerebelar in MRI: a case report of spinocerebellar ataxia type 42 (SCA42)

Felipe Cenicio Juliatti, Camila Rodrigues Nepomuceno[1], Maria Fernanda Hamamoto Leati[1], Nayara de Paula Guerreiro[1], Julian Leticia de Freitas[1], Maria Sheila Guimaraes Rocha[1]

[1]Hospital Santa Marcelina, São Paulo SP, Brazil.

Correspondence: Felipe Cenicio Juliatti; Email: felipe_juliatti@hotmail.com.

Case presentation: A 44-year-old female patient without comorbidities was referred from primary care to the tertiary health service, complaining of imbalance for one year. Her husband reported that she walked as if she were drunk. She denied falls or changes in strength. She denied tremors. She did not present dysphagia, sensitivity, or sphincter changes. She has a familiar history; her mother and her sister have the same clinical picture. Neurological examination showed gait with a broad base, normal deep tendon reflexes, and Romberg negative. During the investigation, his laboratory tests were within normal limits. The brain MRI demonstrated the prominence of cerebellar folia, more evident in the upper and middle third of the vermis and cerebellar hemispheres, inferring volumetric reduction/atrophy. The genetic panel for hereditary ataxias revealed the presence of a heterozygous pathogenic variant in the CACNA1G gene (NM_018896.5:C.5144G>A). This variant is associated with spinocerebellar ataxia 42 (SCA42) and early-onset spinocerebellar ataxia 42 with neurodevelopmental deficit (SCA42ND). **Discussion:** SCA42 is a rare, autosomal dominant disease caused by a heterozygous mutation in the CACNA1G gene on chromosome 17q21. CACNA1G is a gene responsible for the formation of calcium channels, and a mutation in this gene can alter the physiological properties of the channel, resulting in more positive (depolarized) action potentials, indicating that it is a channelopathy. Affected individuals present gait instability and cerebellar signs such as dysarthria, nystagmus, and saccadic intrusions. The age of onset and severity of the disease are highly variable, although most symptoms begin in middle adulthood, with slow progression. Imaging examination demonstrates atrophy of the cerebellum and cerebellar vermis. **Final comments:** Hereditary ataxias are rare diseases, and their diagnosis requires evaluation by qualified professionals and confirmatory genetic tests. Delays in clinical suspicion can increase unnecessary tests and mistaken diagnoses. It is essential to correctly diagnose and carry out multidisciplinary monitoring of these patients to avoid greater social stigmatization and futile therapies.

Correspondence: Artur Menegaz de Almeida; Email: arturomenegaz@gmail.com.

Background: Neuromyelitis Optica Spectrum Disorder (NMOSD) is a devastating, disabling, autoimmune disease with clinical features mainly involving the optic nerves and spinal cord. Rituximab (RTX) is a longstanding CD20-positive B-cell depleter agent used for treating NMOSD. Azathioprine (AZA) and mycophenolate mofetil (MMF) are lymphocyte depleters also used as first-line therapy in these patients, both being associated with less safety and efficacy when compared to rituximab. **Objective:** To assess rituximab safety and efficacy and to directly compare it with azathioprine and mycophenolate mofetil. Additionally, we aim to test these findings with a trial sequential analysis (TSA) to investigate their reliability. **Methods:** MEDLINE, SCOPUS, Web of Science, and the Cochrane Library were systematically searched until April 28, 2024. We included observational studies and randomized controlled trials assessing rituximab therapy in NMOSD patients. In addition, we also included studies comparing rituximab to azathioprine and/or mycophenolate mofetil. All confidence intervals were set at 95%. The trial sequential analysis was applied for both continuous and dichotomous outcomes. Rstudio version 4.3.2, Review Manager 5.4.1, and the TSA software were used for statistical analysis. **Results:** 44 studies were included, of whom 27 were retrospective studies, 8 were prospective studies, and 2 were randomized controlled trials. There were 2047 patients, of whom 1336 (65.26%) were treated with RTX, 417 (20.37%) received AZA, and 294 (14.36%) received MMF. Concerning the annualized relapse rate (ARR) and the expanded disability status scale (EDSS), RTX showed a greater effect size in both: (ARR; MD -1.33; 95% CI 1.07 to 1.60; P<0.000001; I^2=93%) and (EDSS; MD -0.89; 95% CI 0.63 to 1.15; P<0.000001; I^2=67%), respectively. The TSA reinforced this result. The comparison between RTX and both AZA and MMF also tended in favor of RTX in the ARR (MD -0.18; 95% CI -0.34 to -0.02; P=0.026922; I^2=90%) but not in the EDSS, which demonstrated no difference between groups (MD -0.10; 95% CI -0.43 to 0.23; P=0.563; I^2=35%). The TSA was not confirmatory for the analysis of RTX vs. AZA but assured the superiority of RTX over MMF. The time to first relapse was statistically significantly lower in patients treated with RTX (HR 1.7465; 95% CI 1.3343 to 2.2862; P<0.001; I^2=26%). Tolerability analysis also tended in favor of RTX administration when compared to AZA and MMF (occurrence of adverse events; 2.83% vs. 10,33%; RR 0.42; 95% CI 0.19 to 0.91; P=0.027; I^2=49%), which was also demonstrated in the TSA. **Conclusion:** This updated systematic review and meta-analysis with trial sequential analysis assessed the safety and efficacy of RTX compared to AZA and MMF for NMOSD. Our study confirms, through TSA, that RTX is associated with a greater effect in improving ARR, EDSS, and time to relapse, and is associated with better tolerability in NMOSD patients.

Impact of ambient temperature in Teresina/Piauí on multiple sclerosis: an analysis of quality of life, severity of fatigue, sexual performance, and self-medication

Ocílio de Deus da Rocha Ribeiro Gonçalves[1], Francisco Héricles Moreira de Carvalho[1], Samuel de Castro Campos[1], Lara Beatriz Alves Batista[1], Vitor de Deus da Rocha Ribeiro Gonçalves[2], Kayron Rodrigues Lima[1], José Henrique de Melo Feitosa[1], Thalyne Gonçalves Barbosa[1], Hanna Kathrine Vasconcelos Silva Gomes[1], Kelson James Almeida[1]

[1]Universidade Federal do Piauí, Teresina PI, Brazil.
[2]Santa Casa de Miserdicórdia de Belo Horizonte, Departamento de Neurocirurgia, Belo Horizonte MG, Brazil.

Correspondence: Ocílio de Deus da Rocha Ribeiro Gonçalves; Email: ocilio41@gmail.com.

Background: Multiple sclerosis (MS) is a neurological disease that impacts functionality and quality of life (QoL). One aspect of the condition is fatigue, which worsens with heat and in warmer climates. Global warming is a worldwide concern, and recent studies suggest that the current climate of Teresina during the hottest months serves as a prototype for the average temperatures estimated for many areas of the planet in ten years, following the current path of climate change. **Objective:** To analyze the degree of severity of fatigue, sexual performance, QoL, and self-medication in patients with MS in Teresina-PI, comparing periods with higher and milder temperatures throughout the year. **Methods:** This is a prospective observational study conducted between january 2022 and november 2022. It includes MS patients according to the modified McDonald criteria from the MS referral center in the city of Teresina-PI. Patients were evaluated during

the hottest and mildest periods using fatigue scales (FSS), EDSS, QoL, and a self-medication questionnaire. Statistical analysis was performed using SPSS software. The paired t-test was used to compare dependent parametric variables (fatigue and EDSS). The Wilcoxon test was used to compare dependent non-parametric variables (sexual performance and QoL). A one-sample chi-square test was used for a single non-parametric categorical variable (self-medication in cold compared to hot periods). A p-value of <0.05 was considered significant. **Results:** The sample consisted of 41 patients with a mean age of 39.6 years, 65.8% of whom were female. The mean EDSS was 3.04 (hot) and 3.11 (mild), and the total (mean) FSS of the patients during the hot period was 88.24 (2.87), while that of the patients during the cold period was 61.24 (2.04) (p<0.001). Regarding self-medication in the mild compared to the hot period, a decrease was observed in 51.6% of the sample, with 45.2% maintaining the same level and only 3.2% increasing usage (p<0.002). For EDSS (p=0.574), impairment in sexual performance (p=0.122), and QoL (p=0.061), comparing patients in the hot and mild periods, no significant difference was observed in the obtained data. **Conclusion:** Comparing periods with higher and milder temperatures throughout the year in Teresina-PI, there is a significant association between worse fatigue severity in MS patients and higher ambient temperature. Patients tend to significantly reduce self-medication during milder periods of the year, despite maintaining the disease's impact as measured by EDSS.

https://doi.org/10.5327/CBN240920

Impact of benzodiazepine use on quality of life, mental health and cognitive function in the elderly population

Abner Lucas Balduino de Souza[1], João Ricardo Sousa Vasconcellos[1], Déborah Helena Pereira Pinheiro[1], Izabella Gomes de Souza[1], Flávia Gonçalves Vasconcelos[1], Bráulio Brandão Rodrigues[2], Cristiane Teixeira Vilhena Bernardes[1]

[1]Universidade Evangélica de Goiás, Anápolis GO, Brazil.
[2]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Abner Lucas Balduino de Souza; Email: aabnerlucass@gmail.com.

Background: Benzodiazepines (BZD) are among the most prescribed psychotropic drugs in clinical practice, commonly used to treat mood disorders, anxiety, depression, epilepsy, and insomnia. However, their use is increasingly prevalent among the elderly, often without appropriate therapeutic indications, leading to misuse. This misuse is associated with chemical dependence, worsening of delusional conditions, increased risk of falls, and cognitive changes. **Objective:** To compare the aging process of elderly individuals using benzodiazepines with those who do not. **Methods:** This cross-sectional, descriptive study was conducted in Anápolis, Goiás, including individuals over 60 years old. Data were collected after ethical approval using nine questionnaires: sociodemographic, WHOQOL-bref (World Health Organization Quality of Life Instrument), Katz Index, Lawton Scale, GDS-15 (Geriatric Depression Scale), HAM-D (Hamilton Depression Rating Scale), GAD-7 (Generalized Anxiety Disorder 7-item scale), MoCA (Montreal Cognitive Assessment), and Morse Fall Scale. Data were analyzed using IBM SPSS Statistics 29.0.1.0 with Fisher-Freeman-Halton exact test. **Results:** A total of 37 interviews were conducted, with one excluded due to withdrawal, leaving 36 participants (30.6% men). Most were aged 60-69 (50%), married or in a stable union (61.1%), mixed race (69.4%), and had only primary education (63.9%). BZD use was reported by 13 (36.1%) participants, primarily for insomnia (53.8%). Quality of life, measured by WHOQOL-bref, showed that BZD users had lower physical domain scores (mean 56.74%, p=0.058). Depression, assessed by GDS-15, indicated that 75% of those with scores suggesting depression were BZD users (p=0.059). The HAM-D scale also showed a significant association between BZD use and depression (p<0.001). Anxiety levels, measured by GAD-7, showed no significant difference related to BZD use (p=0.610). Cognitive function, assessed by MoCA, revealed that 92.3% of BZD users scored below the cutoff of 26 points, although this was not statistically significant (p=0.114). Fall risk, assessed by the Morse Fall Scale, indicated that 46.1% of BZD users had a low fall risk, and only 15.4% had a high fall risk, compared to 4.3% of non-users (p=0.214). **Conclusion:** The findings suggest that benzodiazepine use in the elderly is associated with poorer physical health, higher rates of depression, and lower cognitive function, although the latter was not statistically significant. These results highlight the need for careful prescription practices to avoid the negative impacts of these drugs on healthy aging.

https://doi.org/10.5327/CBN240921

Impact of delirium and its timing of onset on stroke outcomes

Gabriel Souza Suzart[1], João Pedro Fernandes Gonçalvez[1], Marivaldo Yslan Silveira Leal[1], Luísa Dias Moreno Aravena[1], Thais Barbosa de Oliveira[1], Alex de Cerqueira Silveira Figueiredo[1], Gabriel Souza Medrado Nunes[1], Pedro Antonio Pereira de Jesus[1], Vinícius Bessa Mendez[1]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.

Correspondence: Luísa Dias Moreno Aravena; Email: luisaaravena@ufba.br.

Background: The literature is scarce of studies about the effect of delirium onset on outcome of stroke patients. **Objective:** To determine the frequency of delirium by onset timing, its clinical profile and impact on long-term functional outcome. **Methods:** Prospective cohort of stroke patients admitted to a Brazilian reference stroke unit. Subjects included were older than 18 years with stroke diagnosis within 72 hours of symptoms onset. Delirium was assessed during hospitalization in alternate days during 30 days or discharge with the Confusion Assessment Method for the Intensive Care Unit (CAM-ICU). Delirium was classified according to the day of onset by early (within 3 days from stroke) or late (after 3 days). The main outcome was functional dependence or death in 90 days after stroke, determined by the modified Rankin Scale >2 points. **Results:** A total of 585 patients were included, with a mean age of 62.22 (±13.46) years. Delirium occurred in 114 (19.5%) patients and was associated with infection (p<0.001), with no difference between early and late onset delirium (p>0.05). Patients with Late-onset delirium were more common (71.9%) and had worse outcomes in 90 days compared to those with no delirium [(76.1% vs 34.6%) p<0.001] and no difference compared to early-onset delirium was found [(76.1% vs 70%) p=0.556]. However, there were no significant differences in outcomes in the multivariate analyses, adjusted for age, sex, NIHSS at admission, occurrence of infection during hospitalization and thrombolysis [OR 2.32 (IC95% 0.83-6.49) P=0.108]. **Conclusion:** Delirium presents as a frequent clinical challenge in Stroke Units. Although our study did not find a significant association with poorer outcomes, late-onset delirium may be more prevalent and as morbid as the early-onset. Thus, continuous assessment for delirium during hospital stay remains important, since worse outcomes are present both in early and late delirium. Further research is crucial to fully understand and assess its impact on this patient population.

Impact of glucagon-like-peptide-1 receptor agonists on non-motor symptoms in Parkinson's disease: a systematic review and meta-analysis

Regina Carneiro Leão[1], Caio Rezende Lima[2], Jorge Ferreira Jasmineiro Pitanga[3], Milena Lima Loures[4], Murilo Marmori Cruccioli[5], Filipe Sarmento[6]

[1]Universidade Federal de Pernambuco, Recife PE, Brazil.
[2]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.
[3]Universidad de Buenos Aires, Buenos Aires, Argentina.
[4]Faculdade Ciências Médicas de Minas Gerais, Belo Horizonte MG, Brazil.
[5]Universidade Evangélica de Goiás, Anápolis GO, Brazil.
[6]University of Florida, Florida, USA.

Correspondence: Maria Regina Vendas Carneiro Leão; Email: mariaregina.leao@ufpe.br.

Background: Glucagon-Like-Peptide-1 Receptor Agonists (GLP-1 RAs), initially designed for diabetes management, show potential for treating motor disability in Parkinson's Disease (PD) due to promising pre-clinical and clinical trial results. Previous studies including PD and non-PD populations also suggest GLP-1 RAs may improve cognition and reduce depression and anxiety. Despite the significant impact of non-motor symptoms (NMS) on PD patients' quality of life, these symptoms are often overlooked or briefly assessed in GLP-1 RA studies. **Objective:** To perform a systematic review and meta-analysis to examine the impact of GLP-1 RA administration on non-motor symptoms in Parkinson's disease (PD). **Methods:** We systematically searched PubMed, Embase, and Cochrane databases for randomized controlled trials (RCTs) comparing GLP-1 RAs to no GLP-1 RAs use in PD. Using a random-effects model, we analyzed studies after critical appraisal. Primary outcomes were the mean difference from baseline in reported non-motor symptoms, assessed using the Movement Disorder Society-Unified Parkinson's Disease Rating Scale (MDS-UPDRS) Part I, Non-Motor Symptoms Rating Scale (NMSS), Beck Depression Inventory (BDI), Montgomery-Asberg Depression Rating Scale (MADRS), Montreal Cognitive Assessment (MoCA), and Mattis Dementia Rating Scale (MDRS). Due to variations in the availability of depression and cognitive scales across studies, we used the standard mean difference (SMD) to compare effect sizes for these outcomes. To account for multiple comparisons and reduce the risk of Type I errors, we applied Bonferroni correction (adjusted p-value of 0.0125). Statistical analysis was conducted using Review Manager 5.4.1, and heterogeneity was assessed with I^2 statistics. **Results:** Analyzing data from five RCTs (569 patients, 59% on GLP-1 RA) with 9-15 month follow-ups, GLP-1 RA significantly improved cognitive functions in PD patients (SMD 1.11; 95% CI: 0.29 to 1.94; p=0.0082; I^2: 94%), maintaining significance after adjusting for multiple comparisons. Depression scores showed a medium effect size change towards improvement (SMD -0.49; 95% CI: -0.95 to -0.02; p=0.04; I^2: 69%), but lost significance after correction. NMSS and MDS-UPDRS Part I changes were non-significant (p=0.99 and 0.29, respectively). High heterogeneity was observed in cognitive (I^2: 94%), depression (I^2: 69%), NMSS (I^2: 68%), and MDS-UPDRS Part I (I^2: 96%) outcomes. **Conclusion:** GLP-1 RAs significantly improved cognitive functions in PD patients, suggesting a potential benefit in treating cognitive impairment. However, the trend towards improvement in depression with GLP-1 RA treatment was not statistically significant after adjusting for multiple comparisons. Substantial heterogeneity among studies may have influenced results, affecting the reliability of findings. Future studies should use comprehensive assessments and longer follow-up to better understand GLP-1 RAs' impact on NMS in PD.

Impact of neurodegenerative diseases in Brazil: an analysis of mortality from Alzheimer's and Parkinson's from 2012 to 2022

Júlio César Soares Barros[1], Antonia Cardoso Silva[1], Guilherme Carvalho de Souza[1], Larissa da Silva Almeida[1], Mariana Reis Prado[1]

[1]Universidade Federal de Alagoas, Maceió AL, Brazil.

Correspondence: Júlio César Soares Barros; Email: julio.barros@famed.ufal.br.

Background: Alzheimer's disease (AD) and Parkinson's Disease (PD) are neurodegenerative diseases that pose a growing challenge to public health due to the aging global population. AD is characterized by progressive loss of memory and cognitive functions, while PD is marked by tremors, rigidity, and motor difficulties. Both significantly affect the quality of life of patients and their families, besides representing a substantial economic impact on the healthcare system. Analyzing mortality data related to these diseases is essential to understand their prevalence and to develop effective prevention and treatment strategies. **Objective:** To analyze mortality from Alzheimer's and Parkinson's in Brazil between 2012 and 2022, observing growth trends and correlated factors, distribution by age group, and gender. **Methods:** A cross-sectional, retrospective, and descriptive epidemiological study was conducted using data from the Mortality Information System (SIM/DATASUS) for the period between 2012 and 2022. The analyzed variables included "Region", "Age Group", and "Gender". Population data were obtained from the Brazilian Institute of Geography and Statistics (IBGE) to calculate mortality rates per million inhabitants for each region. **Results:** The total number of deaths between 2012 and 2022 was 265,112, with 221,004 from AD and 44,108 from PD. The Southeast and South regions led, respectively, with 138,421 and 54,096 deaths. A nearly linear increase in mortality was observed over the years, with an 89.6% increase in PD and a 123.9% increase in AD. Analyzing mortality per million inhabitants, the South and Southeast regions continued to lead in the number of deaths, with the South ahead of the Southeast in 2022, reaching 248.03 deaths against 197.67. Regarding gender, both men and women had significantly higher mortality from AD compared to PD. However, women had a higher mortality rate compared to men for both diseases, especially for AD (143,239 against 77,743 deaths). In the age group analysis, mortality increased significantly from the age of 50, with a sharper rise from the age of 70. AD had a much greater impact on the elderly, particularly those over 80 years old, with 168,280 deaths compared to 25,752 from PD. **Conclusion:** The increase in mortality during the analyzed period can be attributed to the aging Brazilian population, as these diseases are more prevalent in the elderly. Furthermore, the improvement in diagnostic methods and greater awareness of these diseases may have contributed to the increase in reported deaths. This growth highlights the need for health policies focused on prevention, early diagnosis, and effective treatment of neurodegenerative diseases. Implementing public health strategies that address these factors is crucial to improving the quality of life and reducing mortality associated with these diseases in Brazil.

Obstructive sleep apnea (OSA) is a disease of upper airways, diagnosed with polisomnography, that is well associated with stroke through diverse mechanisms. Despite that, it still lacks studies about its role in outcomes after thrombolysis in stroke patients. To elucidate the difference of post thrombolysis outcomes in stroke patients with different risks of obstructive sleep apnea (OSA). We performed a transversal study, part of a cohort of stroke patients. Patients were evaluated of risk of OSA with STOP-Bang and SOS scores; also, data of previous comorbidities were collected. Outcomes evaluated were CTI time, internment time, delirium, infection, hemorrhagic transformation and death during internment. We compared groups with T test, Mann-Whitney or chi-square (considering p<0.05). Multivariate analysis with logistic regression was performed for each outcome, considering p<0.05. We obtained 48 patients, 73.5% classified as high risk with STOP-Bang and 49% with SOS score. Patients with high risk of OSA had higher internment (median 11 days; IQR 8-16) and CTI time (median 3 days; IQR 0-5) in comparison with low-risk group (internment median time 9 days IQR 6-14, CTI median time 2 days IQR 0-5). Also, they evolved more to all outcomes, but only delirium was statistically significant (OR=2.2; CI 95% 1.3-3.3; p=0.01). Considering STOP-Bang, age was independently associated to CTI time (OR=1.1;CI 95% 1-1.2;p=0.04) and infection (OR=0.84;CI 95% 0.72-0.98;p=0.02); hypertension with delirium (OR=0.05;CI 95% 0.003-0.95;p=0.04). Although patients with high risk of OSA evolved more to all outcomes, they were not statistically significant, suggesting there is the same safety profile of thrombolysis in both groups. The discrete protector mechanism of hypertension may be due to reduced sample or a maintenance of certain cerebral perfusion that prevents delirium. Further studies are needed to clarify this data.

There is a great association between obstructive sleep apnea (OSA) and cerebrovascular diseases, acting through many pyshiopathological mechanisms. However, the impact of OSA on immediate outcomes in stroke patients remains underdeveloped. This study aims to elucidate which characteristics of patients with OSA significantly affects immediate outcomes. We performed a transversal study, part of cohort of stroke patients. Considering STOP-Bang and SOS scores, we stratified their risk of obstructive sleep apnea. Data of previous comorbidities were collected as well. In the context of immediate outcomes, we evaluated delirium, infection, new stroke occurrence and death during internment. Furthermore, hemorrhagic transformation, CTI time and internment time were also evaluated. We performed an univariate analysis, using T test/Mann-Whitney/chi-square, depending on normality. After, a logistic regression with multivariate analysis. Correlation between scores was done with Spearman or Pearson test. We obtained 430 patients: 69% high risk with STOP-Bang and 50% with SOS. There were significant differences between groups: in the high risk group, 50% were female. In the high risk group of STOP-Bang score, 80% had hypertension, 38.8% had diabetes and 58.4% related previous regular use of medication. Also, median age 65 (IQR 56-72; p=0.003), 19.9% were obese and 22% related alcoholism. About internment time, the results showed median time 10 (IQR 7-16). High risk group evolved more to delirium (p=0.02), infection (p=0.04), death (p=0.04). Age was independently associated to delirium (OR=0.96; CI 95% 0.93-0.98; p=0.003), infection (OR=0.95; CI 95% 0.92-0.97; p<0.001), death (OR=0.95; CI 95% 0.91-0.99; p=0.01); diabetes (OR=2.6; CI 95% 1.11-3.82; p=0.022) to delirium; alcoholism to CTI time (OR=0.32;CI 95% 0.14-0.73; p=0.007). According to SOS score: 50.4% were female. In the high risk group: 76.7% had hypertension, 41% had diabetes, 23% were obese, and BMI median 26.2 (IQR 23.1- 29.6; p=0.015). Besides results, it is noteworthy that patients with high risk of OSA show an absolute number of hemorrhagic transformation, death, and new stroke occurrences during internment. Overall, these observations confirms that STOP-Bang and SOS scoring systems have a similar distribution, reafirming metabolic diseases, hypertension, and diabetes are prevalent in high-risk groups for obstructive sleep apnea (OSA), regardless of the scoring system used. In conclusion, this study elucidates the significant impact of obstructive sleep apnea (OSA) on immediate outcomes in stroke patients due to the observed associations with adverse outcomes such as delirium, infection, death, and new stroke occurrences. Findings reaffirm the need for comprehensive screening and management strategies for OSA in stroke patients to improve outcomes and enhance patient care.

Impact of oxyhemoglobin desaturation on cerebral compliance in patients with obstructive sleep apnea syndrome: a pilot study

André Caldeira Grobério[1], Gilmar Fernandes do Prado[1], Douglas Sousa Soares[1], Ana Flávia Machado Pitz[1], Davi Dantas Muniz[1], Tainã Paulo Zanata Trombetta[1], Letícia Lambert[1], Lucas Martins Teixeira[1], Karla Carlos[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Davi Dantas Muniz; Email: davimuniz@msn.com.

Background: Obstructive sleep apnea (OSA) is a systemic inflammatory disease considered a risk factor for developing cerebrovascular diseases. Considering its complex pathophysiology, OSA also causes hemodynamic dysfunctions, altering CO2 and O2 concentrations and possibly compromising cerebral autoregulation. In this context, little is known about its impact on cerebral compliance. **Objective:** To assess the impact of desaturation on cerebral compliance in patients with mild obstructive sleep apnea syndrome (OSAS). **Methods:** Cerebral compliance was assessed through P2/P1 ratio of the ICP pulse morphology, using the Brain4care® device during Type 1 polysomnography. Statistical analysis was performed using mean and standard deviation, with Student1s t-test for group comparisons (p<0.05). **Results:** Two patients were included, one diagnosed with mild OSAS and one control. The mean age was 38 years ± 0.7. Both patients were female. The mean recording time of the P2/P1 ratio was 362±33 minutes. The patient with OSAS exhibited 57 hypopneas, with 40 of them accompanied by desaturation. The average duration of desaturations was 18 seconds. The mean P2/P1 ratio during desaturations was 1.12. There was no difference in the P2/P1 ratio when comparing events with and without desaturation (p>0.05). The participant without OSAS presented only 2 hypopneas with desaturation, with an average duration of 45 seconds and a P2/P1 ratio of 0.88. Regarding cerebral compliance behavior, we observed an increase in the P2/P1 ratio in the patient with OSAS compared to the control (1.07 vs. 0.88, p<0.0001). The presence of desaturation did not modify the P2/P1 ratio. However, cerebral compliance appears to be reduced in mild OSAS. According to the morphology of the intracranial pressure pulse, three waves are analyzed: P1, corresponding to arterial pulsation; P2, corresponding to cerebral compliance; and P3,

corresponding to aortic valve closure. Based on morphology, we can classify the P2/P1 ratio as normal (0.65 – 1.00) or suspicious of intracranial hypertension when P2>P1. In our study, we found values suggesting morphofunctional alterations in the patient with mild OSAS, classified as at risk for intracranial hypertension. Idiopathic intracranial hypertension has been studied for a long time, but its pathophysiology has not been well elucidated. It primarily affects obese patients, preferably females, and is believed to be multifactorial in etiology. The patient in this study, despite being female, does not present signs or symptoms of idiopathic intracranial hypertension. It is noteworthy that the intracranial pressure varies, with non-hypertensive indices close to the patient's awakening, which raises questions about a possible manifestation of the disease, although a possible subclinical manifestation cannot be ruled out. **Conclusion:** Cerebral compliance is reduced in patients with mild OSAS, and desaturation did not intensify this alteration.

Impact of physical activity on the evolution of symptoms in patients with Parkinson's disease

Tatiana Pizzolotto Bruch[1], Camila Pezente Dal Toe[1], Caroline Liberato Pereira[1], Barbara da Silva Becker[1]

[1]Universidade do Extremo Sul Catarinense, Criciúma SC, Brazil.

Correspondence: Tatiana Pizzolotto Bruch; Email: tatibruch@yahoo.com.br.

This study investigated the impact of physical activity (PA) on the progression of symptoms in Parkinson's Disease (PD), given the absence of pharmacological treatments that halt its progression. A cross-sectional study was conducted with 41 patients diagnosed with PD in Criciúma, Balneário Rincão, and Içara. The PDQ39 questionnaire was used to assess symptom progression, focusing specifically on the effects of PA. The majority of patients (58.5%) engaged in some form of PA, predominantly aerobic activities. Among participants, 31.7% reported significant improvement in PD symptoms after starting PA. There was a statistically significant association between PA practice and improvements in mobility and communication among patients. Additionally, patients who engaged in more than 150 minutes of PA per week showed better outcomes on the PDQ39 quest. In conclusion, the use of physical exercise as an adjunct to PD treatment can provide significant benefits in emotional, communication, and mobility aspects. Aerobic and resistance activities have shown positive impacts on disease progression, although these effects vary from patient to patient.

Impact of renal dysfunction on post-stroke rehabilitation in patients at high risk for obstructive sleep apnea

Juliana Cerqueira Gomes[1], Aurea Maria Lago Novais Castello Branco[1], Marina Soledad Benitez Bitencourt[1], Thaise Braga de Oliveira[1], Renan Carvalho Castello Branco[2]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.
[2]Hospital Municipal de Salvador, Salvador BA, Brazil.

Correspondence: Aurea Maria Lago Novais; Email: aureanovais20.1@bahiana.edu.br.

Literature indicates a link between obstructive sleep apnea(OSA)and kidney impairment. Also,stroke patients with OSA often have longer rehabilitation. However, data of renal impact on stroke recovery is limited. Assess the impact of renal dysfunction on rehabilitation outcomes in high-risk post-stroke patients. We performed a cohort of stroke patients stratified by risk of OSA with STOP-Bang and SOS scores. Also, data of previous comorbidities and renal function (creatinine and urea) at admission, peak, and discharge was assessed, alongside functional outcomes (modified Rankin Scale and Barthel Index) at 3.6, and 12 months. We performed a univariate analysis (T test/Mann-Whitney/chi-square), considering p<0.1, and a multivariate analysis with logistic regression (considering p<0.05). We obtained 415 patients (69% high risk with STOP-Bang and 51% with SOS). Functional outcomes data were available for 49 and 40 patients, respectively. In univariate analysis for STOP-BANG, admission creatinine (median 1, IQR 0.8-1; p<0.01), high creatinine (median 1, IQR 0.9-1; p<0.01), peak creatinine (median 1, IQR 28-50.6; p<0.01),discharge urea (median 38, IQR 28-50; p<0.01), and peak urea (median 49, IQR 36-83; p=0.01) showed difference between groups. For the SOS, discharge urea levels (p=0.02). Regarding functional outcomes, STOP-BANG patients had median Rankin scores of 2 (IQR 1-4) at 3 months,1 (IQR 1-4) at 6 and 12 months; with Barthel medians of 85 (IQR 49.5-95), 93 (IQR 69.5-100) and 95 (IQR 68-100) at the same time. For the SOS group, median Rankin scores were 2 (IQR 1-4) at 3 months,1 (IQR 0.2-3) at 6 months, and 1 (IQR 0.2-3) at 12 months with Barthel medians of 85(IQR 55-98), 94 (IQR 71-100) and 96 (IQR 69-100), at the same time. In multivariate analysis, diabetes in STOP-BANG patients was independently associated with worse Rankin (p=0.02, OR=0.2, 95% CI 0.1-0.6) and Barthel (p=0.05, OR=3, 95% CI 1.4-7) at 3 months, and on the Barthel at 6 months (p=0.02, OR=5, 95% CI 1.2-2). For the SOS group, discharge urea levels were associated with worse Rankin (p=0.01, OR=1.0, 95% CI 1.01-10.6) and Barthel (p=0.01, OR=0.9, 95% CI 0.94-0.99) at 3 months, and on the Rankin at 12 months (p=0.04, OR=1.04, 95% CI 1.01-1.08). The study found significant differences in renal function and functional outcomes among high-risk patients. Diabetes predicts poorer outcomes in STOP-BANG patients, while high discharge urea levels predict worse outcomes in SOS patients. Effective management of these factors is crucial for improving long-term outcomes.

Impact of sars-cov-2 infection on the development of multiple sclerosis

Karoline de Alvarenga Leandro Lobo[1], Saulo Machado Moreira Sousa[1], Sheila Espírito Santo Araújo[1]

[1]Universidade Estadual do Norte Fluminense, Campos dos Goytacazes RJ, Brazil.

Correspondence: Karoline de Alvarenga Leandro Lobo; Email: alvarengalobo@gmail.com.

Background: Multiple sclerosis (MS) is a pathology characterized by inflammatory and autoimmune courses, being the most prevalent and debilitating condition within the spectrum of central demyelinating diseases. As of 2020, its national prevalence was 15 cases per 100,000 inhabitants. Between 2020 and 2022, the world was impacted by a pandemic caused by the SARS-CoV-2 coronavirus, and its infection has been correlated with exacerbation of demyelinating episodes in various autoimmune comorbidities similar to MS. Given this, we question in the scope of this work whether SARS-CoV-2 is capable of triggering MS. **Objective:** Conduct retrospective and prospective analyses of clinical, laboratory, and radiological data from patients infected with SARS-CoV-2, identifying whether this was the trigger for the development of MS. **Methods:** We conducted a survey of the number of hospitalizations for MS and SARS-CoV-2 infections from national data from DATASUS/Tabnet from April 2020 to January 2021. The temporal interval reflects the period from the beginning of the pandemic to the first dose of the vaccine. To determine the existence of a linear relationship between the prevalence of MS and COVID infection during this same period, we performed a regression analysis. **Results:** In the case of the national results obtained from DATASUS, we found a Pearson coefficient of 0.9937 and a p-value less than 0.0001. Similarly, we quantified the number of hospitalizations for MS at Hospital São José do Avaí (HSJA) during the same period and evaluated its correlation with COVID prevalence. With a similar result, the coefficient was 0.9872 and the p-value was less than 0.0001, indicating a strong correlation between the events. **Conclusion:** Therefore, this work contributes to the establishment of the relationship between MS and viral triggers, considering the SARS-CoV-2 virus as one of the responsible triggers for the pathological trigger.

https://doi.org/10.5327/CBN240930

Impact of sleep deprivation on neurological and cognitive functions

Guilherme Eugênio Gil[1], Danielle Delgado Diaz Medina[1], Heloisa Helou Doca[1]

[1]Universidade de Marília, Marília SP, Brazil.

Correspondence: Guilherme Eugênio Gil; Email:

Background: Sleep is a natural and periodic physiological condition of brain activity. It is a period of reversible loss of consciousness that provides physical well-being and mental rest, restoring energy for physical and mental activities. Sleep deprivation can lead to structural changes in sleep, sleep disturbances, drowsiness, reduced alertness and impaired cognitive functioning, including attention, working memory, reaction time, logical reasoning and decision-making. In addition, sleep deprivation can disrupt functional and structural areas of the brain that are associated with cognition and emotion. **Objective:** To evaluate the evidence on the effects of sleep deprivation on neurological and cognitive functions, its underlying mechanisms and implications for healthy cognitive performance. **Methods:** This systematic review obtained 37 scientific articles with the descriptors "Cognition", "Insufficient sleep" and "Sleep Deprivation", articulated by the Boolean operators AND and OR. The search was carried out in the PubMed and Scientific Electronic Library Online databases. The inclusion criteria were publications between 2020-2024, in Portuguese and English, which directly addressed the topic. Articles with no direct relation to the topic and other systematic reviews were disregarded. Case presentations and randomized clinical trials were evaluated, after which 17 articles were included for final analysis. **Results:** Results indicate that sleep deprivation increases the nocturnal concentration of beta-amyloid peptides in cerebrospinal fluid in approximately 10% of a sample of middle-aged elderly people, without significantly affecting cortisol, lactate or glucose. There is a decrease in gray matter volume in the anterior insula, default mode network and thalamus, with a significant interactive effect of age. In addition, sleep duration may be directly related to the cognitive domain of verbal fluency. In young people with attention deficit hyperactivity disorder, there was a significant increase in errors of omission and cognitive reaction time variability. In athletic performance, partial sleep deprivation caused subtle but important damage. In one of the studies, it is seen that there is better performance in the occupational task of a sample of elderly people after adequate sleep, while sleep deprivation did not reach the expected level of performance. **Conclusion:** Sleep deprivation has a negative impact on neurological functions, reducing the volume of gray matter in the anterior insula, especially in the elderly, which affects emotional and associative processes. Sleep deprivation also impairs memory consolidation by reducing the synthesis of proteins necessary for synaptic plasticity, which increases vulnerability to neurological damage. Maintaining consistent sleep of an average of 7 hours per night improves the general health of the individual, regardless of their age group, in order to mitigate neurobehavioral deficits.

Impact of the duration of obstructive sleep apnea on cerebral compliance in humans: a pilot study

Davi Dantas Muniz[1], Gilmar Fernandes do Prado[1], André Caldeira Grobério[1], Douglas Sousa Soares[1], Ana Flávia Machado Pitz[1], Tainã Paulo Zanata Trombetta[1], Leticia Lambert[1], Lucas Martins Teixeira[1], Karla Carlos[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Davi Dantas Muniz; Email: davimuniz@msn.com.

Background: Obstructive sleep apnea syndrome (OSAS) is a common disorder marked by recurrent upper airway collapse during sleep, causing hypoventilation and intermittent hypoxia. These episodes lead to systemic complications, including increased oxidative stress, sympathetic activation, and cerebral microvascular remodeling. These changes may be linked to decreased cerebral compliance and elevated intracranial pressure, though further research is needed to clarify these connections. **Objective:** This pilot study investigates the influence of the duration of obstructive apnea events on cerebral compliance using the non-invasive Brain4care® device. **Methods:** The study included two patients: one with severe OSAS and one healthy control. The diagnosis of OSAS was confirmed by type I polysomnography. Cerebral compliance was assessed through the ratio of P2 and P1 peaks (P2/P1) of the ICP pulse morphology, using the Brain4care® device. Statistical analysis was performed using mean and standard deviation, with Student's t-test for group comparisons ($p<0.05$). **Results:** The mean was 45 years ±10, both females. The OSAS patient had an apnea-hypopnea index (AHI) of 41.3, while the control had an AHI of 4.0. The P2/P1 ratio was significantly higher in the OSAS patient (1.24) compared to the control (0.88) ($p<0.0001$). During REM sleep, the P2/P1 ratio in the OSAS patient was higher (1.31) than during NREM sleep (1.23) ($p>0.0001$). The average duration of obstructive events was 23 seconds in the OSAS patient and 18 seconds in the control ($p<0.0001$). The study demonstrates a significant reduction in cerebral compliance in the OSAS patient, potentially due to prolonged hypercapnia from chronic hypoventilation during sleep. The obstructive events lead to sustained elevations in CO2 levels, causing cerebral vasodilation and increased cerebral blood flow, thereby raising intracranial pressure (ICP). The brain, constrained by the rigid skull, has limited capacity to accommodate this increased blood volume without significant rises in ICP, resulting in reduced compliance. During REM sleep, the OSAS patient exhibited higher P2/P1 ratios than during NREM sleep, suggesting that longer and more frequent obstructive events during REM sleep exacerbate compliance reduction. The extended duration of these events prolongs CO2 retention, intensifying vasodilation and ICP elevation. These results align with previous studies indicating that repetitive extended hypoxic events and sympathetic nervous system activation during apneas contribute to cerebrovascular remodeling and compliance loss. **Conclusion:** Obstructive sleep apnea significantly reduces cerebral compliance, with the duration and severity of respiratory events being key factors. Further studies with larger samples are needed to validate these results, better understand the underlying mechanisms and highlight the importance of early diagnosis and treatment of OSAS.

https://doi.org/10.5327/CBN240932

Impacts of dysarthria on quality of life in Parkinson's disease

Ana Luiza Fabris Moraes[1], Arthur Jun Deguti Hata[1], Vivian Kaori Segawa[1], Emerson Gisoldi[1], Alice Estevo Dias[1], Margarete Jesus Carvalho[1]

[1]Faculdade de Medicina do ABC, Santo André SP, Brazil.

Correspondence: Ana Luiza Fabris Moraes; Email: ana.moraes@aluno.fmabc.net.

Background: Idiopathic Parkinson's disease (IPD) is a chronic, slowly progressive neurodegenerative disorder characterized by plastic rigidity, resting tremor, bradykinesia, and impairment of automatic movements. Dysarthria is one of the most common clinical manifestations in IPD, significantly impacting verbal communication and quality of life. **Objective:** To identify communication difficulties and establish correlations with quality of life in IPD patients. **Methods:** This observational, cross-sectional study was conducted using the "Living with Dysarthria (LwD)" questionnaire in IPD patients, consisting of 10 questions, each with 5 sub-items and 6 response options: 1 (strongly disagree), 2 (disagree quite a bit), 3 (disagree a little), 4 (agree a little), 5 (agree quite a bit), and 6 (strongly agree). All patients were assessed using the Hoehn & Yahr and Unified Parkinson's Disease Rating Scale (UPDRS) parts I, II, III, IV, and V. Pearson's correlation was used to evaluate the relationship between these scales and LwD. **Results:** Responses from twenty-five patients, fourteen women (56%) and eleven men (44%), aged 40 to 80 years, were analyzed. Patients with dysarthria exhibited various communication difficulties: fourteen (56%) had noticeably slower and more slurred speech compared to their pre-disease condition, nine (36%) frequently avoided conversations and had difficulty communicating with family members, eleven (44%) reported a negative impact on self-esteem, sixteen (64%) needed to repeat themselves in conversations, and five (2%) felt treated differently by the people they communicated with. The coefficients found indicated a statistically significant correlation only between the UPDRS scale and the LwD. **Conclusion:** The LwD questionnaire proved effective in analyzing speech difficulties in IPD patients. Dysarthria showed a close correlation with individuals' quality of life, with greater severity of the condition being directly linked to a significant reduction in social well-being. The significant correlation between UPDRS and LwD suggests that worsening symptoms were associated with poorer quality of life. However, this was not the case between the LwD and H&Y, which may indicate that this scale does not capture as well as the UPDRS, regarding the severity of the disease, the quality of life aspects reflected in the questionnaire scores. Finally, the findings highlight the essential need for multidisciplinary intervention, especially speech therapy, in the treatment of this population.

Impacts of hepatic encephalopathy on transplant patients: a systematic review

Loyslene Maria de Paula Bonifácio[1], Leandro de Souza Cruz[1]

[1]Faculdade Suprema, Juiz de Fora MG, Brazil.

Correspondence: Loyslene Maria de Paula Bonifácio; Email: loyslene.med@gmail.com.

Background: Liver cirrhosis is a chronic disease with high morbidity and mortality rates, and its definitive treatment is liver transplantation. Liver transplantation affects the patient's entire organism and functionality and can lead to severe complications. Hepatic encephalopathy is a brain dysfunction that presents as a neurological complication of liver disease and is associated with high re-hospitalization and morbidity rates in patients. **Objective:** To evaluate the impact of hepatic encephalopathy on transplant patients through a systematic review. **Methods:** Randomized controlled trials published in English over the past decade were analyzed, focusing on human subjects aged 18 and older. Data sources included MedLine and SciELO. The search utilized terms from the Health Sciences Descriptors (DeCS), specifically: hepatic encephalopathy, liver transplantation, and cirrhosis. Studies involving patients who presented with hepatic encephalopathy during the liver transplantation process were included, while those with unclear methodologies, available only in abstract form, or where encephalopathy was unrelated to liver pathology were excluded. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) scale was used to enhance the reporting quality of this review. **Results:** Three studies were analyzed, encompassing 477 adult participants with hepatic encephalopathy at some stage of liver transplantation. The effects of hepatic encephalopathy on morbidity, mortality, and neurological functionality during the transplantation process were observed. Statistical tests with a p-value < 0.05 were considered significant. The main symptoms of hepatic encephalopathy are psychomotor deficits, mental confusion, and complications such as intracranial hypertension, edema, and coma. Pre-transplant hepatic encephalopathy directly impacts post-transplant morbidity and mortality and affects the patient's score on the transplant list. Post-transplant hepatic encephalopathy can have multiple causes, such as organ rejection, sepsis, or the neurotoxic effects of immunosuppressants, which increase hospitalization time and impair neurological recovery. **Conclusion:** Hepatic encephalopathy is a significant complication of liver disease, placing a heavy burden on patients, families, and the healthcare system. It is an emergency condition that leads to high re-hospitalization and morbidity and mortality rates, necessitating early diagnosis and management due to its severity. However, further randomized controlled trials are needed to consolidate these observations.

Background: Sepsis is considered an infection associated with organic dysfunction resulting from the body's unregulated response. Experts estimate that sepsis globally contributes to approximately 11 million deaths annually. It is known that in sepsis, the exacerbated production of pro-inflammatory mediators amplifies neurological damage, and that an infectious challenge in childhood can program immune responses throughout life. **Objective:** Therefore, the goal of this study was to find out what effect giving lipopolysaccharide (LPS) during pregnancy had on brain dysfunction in the children of males and females who had severe polymicrobial sepsis as adults. **Methods:** Wistar rats were divided into two groups: saline and LPS, with LPS (100 μg/kg) administered in a single dose on gestational day 9.5, intraperitoneally (i.p.). The offspring of males and females (60 days) were subjected to sepsis by cecal ligation and perforation (CLP) and divided into groups: 1) saline+sham, 2) LPS+sham, 3) saline+CLP, and 4) LPS+CLP. After CLP, survival was assessed, and on the 10th day after, behavioral tests of habituation to the open field and forced swimming were carried out. Then, the cortex, prefrontal cortex, and hippocampus were isolated to evaluate levels of interleukins (IL) 6 and 10. **Results:** The Saline+CLP group reduced survival, in addition to inducing damage to habituation memory in both sexes and depressive-like behavior in females, which was prevented by preconditioning to LPS. Furthermore, it

induced an increase in IL-6 levels in the prefrontal cortex and hippocampus in both sexes, and LPS preconditioning prevented this increase only in the hippocampus of males. In addition to decreasing IL-10 levels in the prefrontal cortex and hippocampus in both sexes, preconditioning to LPS prevented this decrease in both structures in males. **Conclusion:** The present study concluded that preconditioning to LPS during pregnancy protected the offspring from a serious infectious challenge in adulthood.

Impacts of non-prescribed use of methylphenidate by university students: a systematic review

Émile de Carvalho Morais Fraga[1], Giovana Andrade Oliveira[1], Gustavo Alves Cangussú[1], Luídi Neves Nascimento[1], Marcus Vinícius Silva Souza[1], Naila Maria Magalhães Silva[1], Priscila Santos Oliveira[1], Emmanuel Santos Trindade[1], Davi Tanajura Costa[1], Philip George Glass Andrade[1]

Correspondence: Priscila Santos Oliveira; Email: priscilaoliveira35001@gmail.com.

Background: Currently, living in a social context marked by the demand for constant high performance in academic routine, especially in the university environment, associated with the presence in environments that insist on maintaining a parameter of competitiveness, has led students to use psycho-stimulant medications without prescription, such as methylphenidate, used in the treatment of ADHD and narcolepsy. **Objective:** To conduct a systematic review regarding the impacts of non-prescribed use of methylphenidate by university students over the past fourteen years (2011-2024). **Methods:** This is a systematic literature review conducted through articles published in the PubMed and Scielo databases. Publications from 2011 to 2024 were considered, in both English and Portuguese, using the MeSH descriptors "methylphenidate" and "students". Included studies were both observational and analytical, provided they assessed the use of the psycho-stimulant methylphenidate as a performance enhancer in university students rather than for clinical purposes as indicated in the package insert. Exclusion criteria were applied to studies not associated with these criteria. **Results:** 177 articles were found, of which 10 were selected after reading. The analyzed studies revealed that the indiscriminate use of methylphenidate in the academic environment mostly occurs through acquisition from illicit sources, such as peers (56%). However, there is no evidence of significant benefits in the use of this psychostimulant in individuals without a diagnosis justifying therapeutic intervention, with a higher correlation with adverse effects and academic impairment. Individuals who used this drug had a lower mean academic index (7.92) compared to academics who had never used the psycho-stimulant (8.80), suggesting ineffectiveness in enhancing cognitive performance for these students. This low efficacy of methylphenidate may stem from its adverse reactions, such as anxiety (76.7%), tachycardia (40%), rebound effect (30%), fatigue (30%), appetite loss (26.7%), and nausea (13.3%), as well as from incorrect dosing, as in the absence of proper medical prescription, most individuals use sub-doses (12-20mg), insufficient to generate the expected effects of the drug. Among the scarce documented benefits are improved reasoning, memory, and well-being. However, this latter is also related to drug dependence and abuse of other substances. **Conclusion:** The review highlights the dangers of non-prescribed use of methylphenidate by students, emphasizing the academic harm and associated adverse effects. Promoting awareness and implementing control policies are crucial measures to protect student health and face the challenges of this practice in the academic environment, where performance pressure and competitiveness may drive the use of psycho-stimulant medications.

Impacts of the COVID-19 pandemic on the epidemiological profile of stroke in Brazil between 2016 and 2023

Marcelo Pereira de Souza[1], Arthur Faria Jeveaux[1], Clara de Avelar Portela[1], Érika Yumi Mandú[1], Fábio Eiti Mandú[1], Marçal Pizzico[1], Marinalva Pereira dos Santos[1]

[1]Universidade Nove de Julho, Osasco SP, Brazil.

Correspondence: Marcelo Pereira de Souza; Email: marsouzz@hotmail.com.

Background: Stroke is a medical condition that occurs when there is interruption of blood flow to a part of the brain, causing a lack of oxygen and nutrients in this region. Data were collected during and after the COVID-19 pandemic, from January 2020 to December 2023, and it was observed that this condition was responsible for 696,233 hospitalizations and 105,083 deaths. On the other hand, in the pre-pandemic period, between January 2016 and December 2019, there were 621,900 hospitalizations and 96,127 deaths. From this perspective, there is an 11.97% increase in the number of hospitalizations and, approximately, a 9.31% increase in the number of deaths. Based on this result, we see the importance of a well prepared team to recognize these events and treat patients. **Objective:** To analyze the Brazilian epidemiological profile in relation to the increase in the number of stroke cases after the start of the COVID-19 pandemic. **Methods:** Ecological, quantitative and descriptive study, whose data were obtained through consultations carried out in the Hospital Information System (SIH/SUS), through the DATASUS platform, referring to the period from January 2016 to December 2023. Data on hospitalizations and deaths in Brazil were analyzed and compared in the period before and after the COVID-19 pandemic. **Results:** In relation to the national analysis, this condition is present at all ages, with a greater distribution among women aged 0 to 49 years, but in the age range 50 to 79 years it is more prevalent among men. It was observed that, from 2016 to 2019, the number of hospitalizations of women between 0 and 49 years old was 39,644 and the number of deaths was 3,879, between 2020 and 2023, these numbers increased to 44,010 and 4,139, respectively. Among men, aged 50 to 79, the numbers increased from 233,521 hospitalizations and 32,239 deaths between 2016 and 2019 to 265,231 and 36,125, respectively, between 2020 and 2023. In the general overview, in the period between January 2016 and December 2019, there were 621,900 hospitalizations and 96,127 deaths, but, between January 2020 and December 2023, these numbers increased by 11.97% in the hospitalization rate and 9.31% in the of deaths, resulting in 696,233 hospitalizations and 105,083 deaths. **Conclusion:** Based on the analysis of these data, there was a significant increase in hospitalizations and deaths due to stroke, especially in men aged 50 to 79 years, in Brazil, during the pandemic period.

Implications of detecting clinical manifestations of dysphagia in Parkinson's disease

Vivian Kaori Segawa[1], Arthur Jun Deguti Hata[1], Ana Luiza Fabris Moraes[1], Margarete Jesus Carvalho[1], Alice Estevo Dias[1], Emerson Gisoldi[1]

[1]Faculdade de Medicina do ABC, Santo André SP, Brazil.

Correspondence: Vivian Kaori Segawa; Email: viviankaorisegawa@gmail.com.

Background: Parkinson's disease (PD) is the second most common neurodegenerative disease in the world and mainly affects the elderly. Dysphagia is one of the most prevalent clinical manifestations (70-100%). **Objective:** To detect the manifestations of dysphagia in patients with PD. **Methods:** An observational, cross-sectional study was carried out using the Dysphagia Detection Questionnaire for Patients with Parkinson's Disease (SDQ-DP), made up of 15 questions about swallowing alterations, 13 of which required the patient to mark the frequency of symptoms from 0-3, 0 being never and 3 being very frequent, and 2 of which required a yes or no answer. The instrument's cut-off point is 11 points; a score equal to or greater than this value indicates a risk of dysphagia. In order to identify the clinical condition of patients with PD, the Unified Parkinson's Disease Rating Scale (UPDRS) parts I, II, III, IV and V and the Hoehn & Yahr (H&Y) scale were used; the statistical test used was Pearson's sample correlation. **Results:** 25 PD patients aged between 40 and 80 years participated, 14 patients (56%) were women and 11 patients (44%) were men. The moderate correlation between UPDRS and SQD-DP (p=0.44) indicates that there is a relationship between the severity of the aspects investigated by the scale and the severity of the statements contained in the evaluation instrument. The weak correlation between H&Y and SDQ-DP (p=0.25) indicates that the H&Y scale does not fully cover the level of disease involvement and its clinical manifestations. It was found that 3 patients (12%) reported food/liquid coming out of their nose after eating/drinking; 5 patients (20%) reported difficulty breathing during meals; 6 patients (24%) reported the presence of leftover food in their mouth after swallowing and that chewed food escaped out of their mouth, and they had difficulty swallowing pasty food; 7 patients (28%) coughed while swallowing solids and felt their voice change after swallowing food or liquids; 8 patients (32%) reported food stuck in their throat while eating; 9 patients (36%) tried to swallow chewed food several times, had difficulty swallowing solids, reported coughing while swallowing liquids and difficulty swallowing saliva outside of meals; 10 patients (40%) noticed an increase in saliva in the mouth and 11 patients (44%) had difficulty chewing solids. There were 19 scores (76%) below 11, representing a low risk of dysphagia, and 6 scores (24%) equal to or greater than 11, with the highest score being 30. **Conclusion:** This study exposes the main complaints and complications related to dysphagia in patients with PD and how they negatively affect quality of life through limiting and uncomfortable aspects. The SDQ-DP proved to be useful in instituting appropriate and early multidisciplinary treatment in order to avoid complications and ensure an improvement in patients' quality of life.

Correspondence: Vinícius Andreata Brandão; Email: viniciusandreatab@gmail.com.

Case presentation: Female, 24 years old, from the south of Bahia, seeks orthopedic service complaining of mobility difficulties. At the age of 13, she began to have a progressive mobilizing difficulty of her right lower limb, and after a few years, both limbs were injured, with gradual evolution associated with urinary retention and constipation. She denied pain, paresthesia or anesthesia. The patient was born by vaginal delivery at eight months

and she was exclusively breastfed until seven months of age. Her cognitive, motor and gait development were unchanged. No comorbidities and updated vaccinations. Cardiovascular, respiratory and abdominal examinations were unchanged. The neurological assessment showed grade 2 proximal strength in the right lower limb, grade 3 strength in the left lower limb and grade 5 strength in the upper limbs. Osteotendinous reflexes 4+ globally. Patellar clonus 1+ and mandibular clonus 2+. Plantar cutaneous reflex in bilateral extension. Hofmann and Trömner present bilaterally. Cognitive, cranial nerves and sensitivity assessments were unchanged. Due to the findings of the physical examination, the patient was referred to the neurology department. The patient had an electroneuromyography suggesting paraparesis of the lower limbs, compatible with spinal cord involvement at the lower thoracic level. A magnetic resonance imaging of the neuroaxis revealed atrophy of the thoracic spine, corroborating the diagnosis of spastic paraparesis. The hypotheses of sporadic or tropical spastic paraparesis, caused by HTLV virus infection, were put forward, and then confirmed later by serology for the virus. The treatment was started with botulinum toxin and physiotherapy, with symptom improvement. **Discussion:** Type 1 Human T-cell lymphotropic virus (HTLV-1) associated myelopathy or tropical spastic paraparesis is a severe neurological disease that usually affects adults between the ages of 30 and 50. It leads to chronic and progressive degeneration of upper motoneurons in the Central Nervous System, which can lead to severe motor disability. It is expected that, after 10 years of progression of the disease, 50% of patients will need a wheelchair, while the others will need other devices to help them walk. In this summary, we present a case of an 11-year evolution tropical spastic paraparesis in a 24-years-old patient from an endemic area for HTLV-1. It is important, therefore, to highlight the onset of the condition in a young patient, with 11 years of evolution, who does not depend on a wheelchair for locomotion. In addition, the diagnosis was suspected after a complete neurological physical assessment, highlighting its importance. **Final comments:** In this paper, we reinforce the importance of routine neurological physical examination, especially in patients from an endemic area for HTLV-1, since the findings in the case presented were essential for the patient to be referred to the appropriate service

Improvement clinic to an unusual drug treatment in short-lasting unilateral neuralgiform headache attacks with cranial autonomic symptoms (SUNA): a case report

Leonardo Monteiro Lauria[1], Pedro Augusto Sampaio Rocha Filho[2], Alex de Novais Batista[1], Iago César Lopes Tenório de Cerqueira[1], João Herculano Lins[1], Maria Clara Arcoverde Santana[1], Renato Maciel Freire de Paula e Silva[1], Virgílio Sátyro da Nóbrega Segundo[1], Caio César Alves Lins de Oliveira[1], Lucas de Souza Pessoa[1]

[1]Hospital Universitário Oswaldo Cruz, Recife PE, Brazil.
[2]Universidade Federal de Pernambuco, Departamento de Neuropsiquiatria, Recife PE, Brazil.

Correspondence: Leonardo Monteiro Lauria; Email: leonardolauria09@gmail.com.

Case presentation: Woman, 60 years-old, reports having right periorbital pain for 1 year, with shock. The pain episodes lasted 3 minutes, were associated with tearing ipsilateral to the pain, and had a frequency of 5 to 10 attacks per day. Furthermore, touch the right face and water in the bath were reported as triggers. MRI and contrast-enhanced cranial MRI angiography showed no significant abnormalities. Also, she used carbamazepine 200 mg/day for 3 months, however, as there was no improvement in pain, this was replaced by valproic acid (250 mg 12/12 h). With this drug, she remained pain free for 2 years and 3 months. After this period, the drug was suspended. Since then, the patient has progressed for over a year without new attacks. **Discussion:** SUNCT (short-lasting unilateral neuralgiform headache attacks with conjunctival injection and tearing) and SUNA (short-lasting unilateral neuralgiform headache attacks with cranial autonomic symptoms) are trigemino-autonomic headaches characterized by ultra-rapid attacks that last from 1 to 600 seconds and differ from each other in that SUNA does not present conjunctival hyperemia and tearing at the same time. There are three first-line prophylactic treatment options for these headaches: lamotrigine, topiramate and gabapentin. Our patient evolved with an excellent drug response to valproic acid. Only 6 patients with SUNCT had previously reported improvement with this drug. Our case of SUNA may have been one of the few described with improvement in the patient's pain with the use of valproic acid. **Final comments:** SUNCT (short-lasting unilateral neuralgiform headache attacks with conjunctival injection and tearing) and SUNA (short-lasting unilateral neuralgiform headache attacks with cranial autonomic symptoms) are headaches traditionally described as difficult to treat. Although valproic acid is not among the first-line medications for the treatment of these headaches, the excellent response in our case to this drug contributes as evidence to consider this drug as a therapy.

Improvement of neuropathic pain related to spinal cord injury using combined transcranial direct current stimulation and neuromuscular electrical stimulation: a case report

Cezar Sabino Pereira da Silva[1], Ana Clara Dias Pereira[2], Vívian Santos Xavier Silva[1], Jean Marcos de Souza[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.
[2]Pontifícia Universidade Católica de Campinas, Campinas SP, Brazil.

Correspondence: Cezar Sabino Pereira da Silva; Email: cezarsabinop@gmail.com.

Case presentation: A 32 Y.O. male with neuropathic pain from a T12/L1 traumatic spinal cord injury (SCI) since 2019 underwent a weekly protocol of combined transcranial Direct Current stimulation (tDCS) at 2mA targeting the motor precentral region and 20 minutes of functional electrical stimulation of the bilateral femoral quadriceps. Initial comprehensive assessments of pain and quality of life were conducted using the Neuropathic Pain Symptoms Inventory (NPSI), McGill Pain Questionnaire (MPQ), Pain Quality Assessment Questionnaire (PQAS), Short-form Health Survey-36 (SF36), and Quality of Life Index Spinal Cord Injury III (SCI III). The American Spinal Cord Injury Association Impairment Scale (AIS) evaluated his spinal cord status. After 12 weeks, these assessments were repeated. The study was approved by the institution's Ethics Committee, and the patient provided written consent. By the end, AIS level and classification remained unchanged, and no side effects were reported. There was a reduction in deep and superficial pain, with evoked and continuous pain remaining stable. Paroxysmal pain showed contradictory results between PQAS and NPSI, precluding definitive conclusions. MPQ showed a 50% reduction in the affective component of pain. Significant improvements in quality of life and functionality metrics were observed in SCI III, along with enhancements in all dimensions of SF-36, some of which were notably enhanced. The questionnaire revealed significant improvements in vitality, sociability, physical condition, and pain, enhancing daily performance and capabilities. Pain characteristics became more benign, with alterations in type, and both recurrence and duration of pain decreased. **Discussion:** Neuropathic pain is a common issue in individuals with SCI, resulting from damage to the somatosensory system leading to neuronal hyperexcitability. Drug-based treatments for neuropathic pain tend not to have satisfactory effects. The intervention reduced some somatosensory pain features while others remained stable. However, the substantial improvement in quality of life suggests an objective decrease in pain through indirect measures, which may be more practical than analog scales. The neuropathic pathophysiology of pain in SCI involves central sensitization, which tDCS may modulate, partially explaining the results. Since chronic pain impacts quality of life through negative emotions, this case report suggests that combined stimulation may modulate the emotional response to pain, not just its sensory characteristics. The decreased recurrence and duration of pain may be related to the patient's improved well-being. **Final comments:** The therapy was safe and feasible, resulting in substantial improvements in quality of life. Therefore, this approach could fill a gap in patient care, given the lack of effective drug-based treatments for neuropathic pain. This case report highlights the importance of future experimental trials with combined neurostimulation.

Correspondence: Ayla Morais Vitório Guerra; Email: aylaguerra1@hotmail.com.

Background: The therapeutic use of dopaminergic agonists for Parkinson's disease (PD) treatment may cause, as an adverse effect, impulse control disorder (ICD), where the desire to engage in certain activities is independent of social, physical or psychological harm. It can lead to financial difficulties, relationship problems, mental health problems and even legal problems. **Objective:** To describe the frequency of ICD in PD patients and analyze their quality of life (QOL). **Methods:** Cross-sectional study carried out between 2023-2024, patients who responded positively to at least one question on the Questionnaire for Impulsive-Compulsive Disorders in Parkinson's Disease Rating Scale (QUIP-CS), indicating the presence of CDI. Clinical, social and epidemiological data were collected, in addition to the application of the following scales: Parkinson's Disease Questionnaire (PDQ-39), Unified Parkinson's Disease Rating Scale-Part III (UPDRS-III), Mini-Mental State Examination (MMSE), Beck Depression Inventory (BDI), Non-Motor Symptoms Scale (NMSS), and the Hoehn and Yahr scale (HY). **Results:** Sample consisted of 25 PD patients, 72% male, with a mean age of 65.4 years (±8.3) and a mean disease duration of 11.8 years (±3.7). Types of ICD identified included pathological gambling (16%), excessive purchases (16%), hypersexuality (24%), binge eating (20%) excessive medication use (16%) and other behaviors (44%). More than one compulsive behavior were found in 24% and 52% reported that the compulsive disorder had no negative impact on their lives. The median Levodopa Equivalent Daily Dose (LEDD) with 1100mg (450-2422). QOL, measured by the PDQ-39, had a mean total score of 44.2 (±5.5). Severity of motor symptoms, assessed by the UPDRS-III, had a mean of 44.6 (±17.8), we consider a moderate value between 25-50. The MMSE revealed a median of 26 (9-30). Depression assessment, conducted using the BDI, indicated a mean of 15.6 (±10.1). The mean sum of non-motor symptoms, evaluated by the Scales for NMSS, was 92.6 (±52.7) and 56% of participants have disability level 2 on HY scale. Types of ICD didn't demonstrate a difference in impact on QOL.

Bivariate tests showed a positive association between the total PDQ-39 and the sum of NMSS (r=0.67, p=0.00). A moderate correlation was also observed between UPDRS-III and the total PDQ-39 (r=0.54, p=0.05). Additionally, the correlation between the Beck Depression Inventory and the total PDQ-39 was moderate (r=0.49, p=0.01), and the difference in HY is associated with differences in QOL, with post hoc analysis indicating that HY 4 is associated with worse QOL compared to HY 2 (p=0.048). **Conclusion:** ICD has a significant multidimensional impact on the QOL of participants, highlighting the need for comprehensive therapeutic interventions that address the physical and psychosocial aspects of the disease to improve the overall QOL of these patients.

In addition to Parkinson's disease, a different presentation of the LRRK2 mutation

Sephora Sabrina Candido de Almeida[1], Ana Carolina Gomes[1], Yngrid Dieguez Ferreira[1], Alexandre Shoji[1], Isabela Martins de Freitas[1], Diogo Haddad Santos[1]

[1]Irmandade Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Sephora Sabrina Candido de Almeida; Email: sephora_sabrina@yahoo.com.br.

Case presentation: 58 years old, female, previously healthy , housewife, started experiencing changes in mood and behavior 5 years ago, repeating the same activity several times and becoming disoriented in familiar places. Within 2 years, the patient developed complete loss of self-care capacity. After another year, he presented her first seizure and progressively began to have difficulty with language (naming and repetition). In the mini mental state examination (MMSE) in August 2022, the patient scored 11 (loss in memory, attention, evocation and language) with clinical dementia rating scale (CDR) 1. In April 2024, patient unable to perform MMSE, with CDR 3. Imaging examination (magnetic resonance imaging of the skull) at the beginning of the condition (2021) without changes. After follow-up and exclusion of common causes of dementia syndromes, it was decided to request genetic testing considering a young patient with a progressive condition without other examination findings. LRRK2 gene found – AUTOSOMAL DOMINANT PARKINSON DISEASE. Patient remains under outpatient follow-up. **Discussion:** This case report describes a patient with a mutation in the LRRK2 gene, who presents with a dementia syndrome, but without symptoms of parkinsonism. This clinical presentation is atypical, given that mutations in the LRRK2 gene are most frequently associated with late-onset Parkinson's disease (PD). The absence of parkinsonian symptoms and the isolated presence of dementia in this patient raise important questions about the phenotypic variability associated with LRRK2 mutations and the possible mechanisms underlying the observed cognitive decline. Mutations in LRRK2, especially G2019S, are well documented to cause PD with significant phenotypic variability. Previous studies have demonstrated that, in addition to the typical motor symptoms of PD, some individuals with LRRK2 mutations also experience non-motor symptoms, including cognitive and psychiatric disorders. However, cases of isolated dementia without parkinsonism are rarely reported. The absence of parkinsonian symptoms in a patient with a LRRK2 mutation is unusual but not unprecedented. Isolated case studies indicate that the phenotypic expression of LRRK2 mutations may be influenced by additional genetic factors, epigenetic modifiers, and environmental factors. These cases reinforce the need to consider a broad approach when evaluating the symptoms and prognosis of LRRK2 mutation carriers. **Final comments:** The present case report contributes to the understanding of the phenotypic variability of LRRK2 mutations, highlighting the possibility of an isolated presentation of dementia. This case reinforces the need for further research to elucidate the underlying mechanisms and to develop targeted therapeutic strategies.

Glioblastoma multiforme (GBM) is the most frequent brain cancer in adults and remains incurable despite advancements in cancer therapeutics. The intense angiogenesis in GBM creates a chaotic blood vessel network, contrasting with the organized structure of healthy tissue, contributing to its resistance to conventional therapies. To enhance capacity to treat patients, different therapeutic approaches are required. Among them is magneto hyperthermia (MHT), where magnetic nanoparticles are introduced into the tumor and an alternating magnetic field is applied resulting in localized heating that selectively targets tumor cells at 42°. Preclinical investigation of MHT therapy is crucial, and with the organ-on-a-chip device it is possible to overcome the limitations of in vivo models and replicate the physiological microenvironment of tissues and organs. In silico studies are essential in developing microfluidic devices, addressing the complexity of biological systems by utilizing simulations that predict treatment dynamics, and further investigate the contribution of tumor vascular networks to heat dissipation. This work aimed to analyze the efficiency of heat dissipation in vascular networks under MHT, comparing healthy and tumorous tissue networks. We created two chip designs, based on healthy and tumorous vascularization, grounded on studies of GBM vessels microstructure. The COMSOL Multiphysics software was used to simulate conditions in microchips and analyze the thermal behavior in both geometries.The flow studies analyzed temperature variations over time, mostly focusing on the impact of flow rate variations (0, 1, and 100 μL/min) and their effects on fluid dynamics parameters. Furthermore, we investigated the influence of nanoparticle concentration, from 0.25 to1mg/mL, on temperature distributions over time. Regarding maximum velocity, the healthy design had 4.5 times faster flow at μL/min and 10 times at 100 μL/min than the complex model. In temperature analyses at 0μL/min, no differences were noted between the designs, yet a higher heat concentration was observed compared to the 1 and 100μL/min models. Furthermore, flow analyses revealed a greater heat concentration in the tumorous design, reaching a difference of 4°C, indicating less efficient heat dissipation under irregular pathways. Additionally, higher nanoparticle concentrations led to a linear increase in temperature, suggesting that the tumorous system retains greater heat concentration and reaches higher temperatures within the same timeframe, with a maximum difference of 3.92°C at 0.5mg/mL concentration. This study introduces an innovative microfluidic device for assessing thermal tumor therapies, which allowed the assessment of the considerable influence of vascular architecture, fluid flow, and nanoparticle concentration on the effectiveness of MHT therapy on in vitro studies. Representing a notable advancement in the field of thermal therapy for brain tumors and beyond.

Inborn errors of immunity: neurological phenotypes, clinical features and genetics of a cohort of 27 patients

Renan Brandão Rambaldi Cavalheiro[1], Kaliny Oliveira Peixoto[1], João Paulo Barile[1], Patrícia Marques Mendes[1], Igor Braga Farias[1] , Paulo de Lima Serrano[1], Wladimir Bocca Vieira de Rezende Pinto[1], Paulo Victor Sgobbi de Souza[1], Acary Souza Bulle Oliveira[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Renan Brandão Rambaldi Cavalheiro; Email: renan.rambaldi@icloud.com.

Background: The inborn errors of immunity (IEI) are a heterogeneous group of monogenic conditions that encompass autoinflammatory syndromes, complement deficiencies, diseases of immune dysregulation and defects of intrinsic and innate immunity and one marrow failure. While individually these conditions can be considered rare, ultra rare (less than 1 case per million people) and some with single-digit case reports, they are common as a group and can present with virtually any constellation of signs and symptoms. A striking feature of some IEIs is the potential of secondary autoimmunity. While IEI are considered multisystem disorders with well described features, such as periodic fevers and arthralgia, there is an increasing body of evidence of isolated neurological presentations, that can be either the sole manifestation of some of these conditions or precede systemic involvement. The recognition of those syndromes is vital, as they are potentially treatable, such as the use of IL-1 inhibitors in TNF receptor-associated periodic syndrome (TRAPS) or the use of TNF blockers in deficiency of adenosine deaminase 2 (DADA2). **Objective:** Describe the demographics, clinical presentation and genetics of a cohort of 27 patients with inborn errors of immunity from an outpatient neuromuscular clinic. **Results:** Of the 27 patients with genetically confirmed IEIs, age at presentation varied from 1 year of age to 62 years of age. 18 patients had a final diagnosis of an autoinflammatory syndrome: 6 patients with Aicardi-Goutières syndrome (AGS), 3 patients with TRAPS, 3 patients with cryopyrin-associated periodic fever syndrome (CAPS), 2 patients with NOD2- related autoinflammatory syndromes. Their phenotypes ranged from pure hypotonia (floppy infant syndrome) to a classic autoinflammatory phenotype with additional neurological findings (dysautonomia, polyneuropathy) and leukodystrophic changes in the AGS patients. 9 patients presented with individually ultra-rare immune dysregulation genes that, while producing immune deficiencies also caused secondary autoimmunity. These patients presented with recurrent sinopulmonary infections and transient arthralgias. The most common secondary autoimmune disorders observed were myasthenia gravis, observed in 4 patients, and stiff-person syndrome (SPS), observed in 3 patients. **Conclusion:** While rare, inborn errors of immunity need to be considered in the differential diagnosis of many neurological conditions, as their presentation can vary substantially. The present data underscore the importance of careful phenotyping of any "outlier" clinical feature, as it may be the protean manifestation of a much rarer disease, and may point the neurologist to a treatable condition.

Correspondence: Emanuel Henrique dos Santos; Email: hds.emanuel@gmail.com.

Background: Congenital malformations are alterations in the embryonic process. In Brazil, the main ones are congenital heart malformations, Down syndrome, and Neural Tube Defects (NTDs). This study aims to analyze malformations of the nervous system. **Objective:** To expose the prevalence of sex in the incidence of hospitalizations and mortality from these malformations in Brazil. **Methods:** An epidemiological study was conducted using the DATASUS database, focusing on the Hospital Morbidity database of the Unified Health System (SIH/SUS) and Live Births (SINASC). Data collection was carried out from 2019 to 2022, with records of hospitalizations per period and deaths by age group. The variables analyzed were sex and age. The applied ICD was Spina Bifida and Malformations of the Nervous System, with analysis restricted to children under 1 year. Incidence was calculated using the formula: incidence rate = number of cases of the disease in the period / number of people exposed to the risk of acquiring the disease in the period (live births) x 10^5, while mortality followed the standard formula, also with exponent 5. **Results:** The total incidence of hospitalizations was 102.85 per 100,000 inhabitants, with female predominance (104.25) compared to male (101.50). Regarding mortality, females also had higher numbers than males, with 8.25x6.97 deaths per 100,000 inhabitants. Over the analyzed period, the incidence of hospitalizations per one hundred thousand newborns was higher for females in the first two years, becoming higher for males in the following two years: 95.24 for males and 100.39 for females in 2019; 100.09 for males and 100.39 for females in 2020; 108.06 for males and 106.57 for females in 2021; 103.15 for males and 99.61 for females in 2022. However, mortality per one hundred thousand newborns remained higher for females throughout the period: 7.20 for males and 7.83 for females in 2019; 7.30 for males and 8.86 for females in 2020; 6.50 for males and 7.73 for females in 2021; 6.87 for males and 9.03 for females in 2022. **Conclusion:** Females present higher mortality, while the incidence of hospitalizations was higher for females in 2019 and 2020, and for males in 2021 and 2022. It is crucial to highlight the importance of prenatal care to raise awareness among patients about teratogenic substances and preventive measures for neurological malformations, such as gynecological emergencies that can affect blood supply to the fetus, and various infectious diseases. Further studies are needed not only to explore new ways of preventing malformations but also to ensure the physical and psychosocial well-being of patients, as provided by law.

Incidence and predictors of late seizure after cerebral venous thrombosis: an ambispective cohort

Graziele Carolina Araújo Soares[1], Júlia Barreto de Farias[1], Pedro Fernandes Abbade[1], Lucy Rodrigues Ribeiro[1], Cárita Victória Carvalho de Santana[1], Isabella Reis Vieira[1], Israela Souza Brito Santos[1], Ana Beatriz Cazé Cerón[1], Bruna Guilherme Martendal[1], Jamary Oliveira-Filho[1]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.

Correspondence: Graziele Carolina Araújo Soares; Email: grazielemedicina@gmail.com.

Background: Cerebral venous thrombosis (CVT) is a rare cause of stroke with a high incidence of seizures, either acute (AS) or late (LS). The chance of recurrent seizure after an episode of CVT is about 11%, but there is a lack of Brazilian studies on the subject. **Objective:** To evaluate the frequency and predictors of LS after CVT. **Methods:** Ambispective cohort using medical records of consecutive individuals treated at a specialized outpatient center in Salvador-BA between 2008 and 2024. Those with a previous diagnosis of epilepsy and a follow-up time < 6 months were excluded. LS were defined as seizures occurring > 14 days after the diagnosis of CVT. To identify predictors of LS, we used multivariate Cox regression. **Results:** We included 64 participants with CVT, with a median follow-up time of 38 months (IQR: 18-81.5). Seizures were presented by 32 individuals (50%): 30 (47%) had AS and 16 (25%) had LS, and in the LS group, 88% (14/16) of the participants had AS. The baseline characteristics among participants with and without LS were similar, except for a higher frequency in the LS in afrodescendants (53% vs 17%, p=0.035), with hemorrhagic transformation (56% vs 23%, p=0.013), cortical infarction (56% vs 19%, p=0.009) and AS (88% vs 33%, p<0.001). The clinical manifestations of CVT were similar in LS and non-LS participants, except for a lower frequency in the LS group of headache (69% vs 91%, p=0.039) and nausea and vomiting (19% vs 49%, p=0.034). Participants with LS compared to participants without LS had a higher frequency of deep venous thrombosis (27% vs 6.3%, p=0.049) and protein C deficiency (33% vs 0%, p=0.017). In the survival analysis, we identified as multivariate predictors of LS: AS (HR=5.55; 95% CI, 1.05-29.21), use of dabigatran (HR=0.16 compared to warfarin; 95% CI, 0.03-0.81) and visual symptoms (HR=0.19; 95% CI, 0.04-0.89). **Conclusion:** In CVT, 25% of the participants had LS. AS were associated with increased frequency of LS, while dabigatran (vs. warfarin) use and visual symptoms were associated with decreased frequency of LS.

Background: Viral neuroinfections present a significant public health challenge, especially in children, due to their potential severity and long-term complications. Factors such as environmental conditions, socioeconomic status, and healthcare access can influence their incidence, particularly in regions with distinct epidemiological profiles, as the Northern region of Brazil. **Objective:** To analyze pediatric hospitalizations in Brazil using data from the Hospital Information System (SIH/SUS) via the DATASUS platform. Employing a quantitative and descriptive approach, it examines variables such as sex, race/ethnicity, epidemiological profile, hospitalizations by state, endemic region, age group, and mortality rate. The goal is to identify patterns and trends to inform effective public health interventions and highlight areas requiring policy attention. **Methods:** This retrospective, quantitative, and descriptive study utilized secondary data from the Hospital Information System (SIH/SUS) via the DATASUS platform. The dataset spans from January 2018 to December 2023, encompassing individuals aged 0 to 14 years, and specifically focuses on hospitalizations within the Brazilian public health system (SUS). Descriptive statistical methods were employed to analyze variables such as the year of hospitalization, sex, race/ethnicity, hospitalizations by state, age group, and mortality rate. **Results:** From 2018 to 2023, in the Northern region, there were 1,031 hospitalizations for viral neuroinfections in children aged less than one to fourteen years old. Pará was the leading state with 391 (37.9%) admissions. From all the cases, 579 (56.2%) were male and 452 (43.8%) were female. The majority (590 or 57.2%) were patients of brown skin color. Acre had the highest mortality rate (5.77), followed by Pará (5.12), whereas Tocantins had the lowest (1.02). Most hospitalizations occurred in children aged 1 to 4 years (33.17%). **Conclusion:** This study provides insights on the incidence and risk factors of viral neuroinfections in Northern Brazil's pediatric population. The data revealed a significant burden of these infections, with Pará being the most affected state. The findings also highlight disparities in mortality rates among different states, underscoring the need for targeted interventions. Overall, this study underscores the importance of continuous surveillance and public health strategies to prevent and manage viral neuroinfections in children, particularly in regions with higher prevalence rates. Further research is warranted to explore the underlying factors contributing to these infections and to develop more effective prevention and treatment measures.

Incidence of atrial fibrillation in patients with ischemic stroke due to large vessel occlusion undergoing chemical thrombolysis in a stroke reference unit in 2022

Paulo Victor Santos Machado[1], Frederico Otto Flores Moraes[1], Vitor Bonk Rizzo[1], Isadora Candotti Sperotto[1], Sarah Protásio Bonete[1], Julia Duarte Couto de Cristo[1], Felipe Bernardo Costa Ramos[1], Marcos Seefeld[1], Paola R. González[1], Lisseth F. V. Reyes[1]

Correspondence: Paulo Victor Santos Machado; Email: paulovictorsmachado@gmail.com.

Background: Approximately 30% of ischemic strokes are caused by large vessel occlusion (LVO), characterized as occlusions of the proximal systemic arteries (M1), mid-branch losses (M2), basilar, or intracranial internal carotid arteries (ICA), resulting in greater morbidity and mortality when compared to an ischemic stroke involving smaller vessels. A well-established risk factor is atrial fibrillation (AF), with a doubled prevalence in patients with arrhythmia who have had LVO, when compared to other subtypes of ischemic stroke, with cardioembolism being the cause of almost half of the cases, with more than half of these attributed to AF. Despite this reality, 30% of cases are considered to have cryptogenic etiology, which is defined by criteria for embolic stroke of undetermined origin (ESUS). Initial studies suggest that empirical anticoagulation after ESUS is not superior to antiplatelet therapy, whereas the presence of AF after stroke typically requires anticoagulant treatment by risk classification calculation. Understanding that the identification of AF after stroke typically alters the treatment strategy for secondary stroke prevention, the use of extended cardiac monitoring for AF is therefore critical in the assessment of stroke ESUS. **Objective:** To analyze the incidence of atrial fibrillation and the epidemiological profile of patients who were chemically thrombolysed due to a stroke caused by large

vessel occlusion. **Methods:** Observational, cross-sectional and retrospective study from the year 2022, through analysis of medical records and complementary exams of patients who were treated in a stroke reference unit. **Results:** During the studied period, of the 35 patients with LVO, 12 (34.29%) had AF. The average age of these patients was 75.16 years (ranging from 65 to 92 years). The main occluded branch was the M1 portion of the middle cerebral artery, representing 66.67% of cases, followed by the M2 portion with 25% and the internal carotid artery with 8.33% of cases. **Conclusion:** The results are in line with the literature, with an incidence of approximately 33% of AF known at admission. The epidemiological data are also in agreement, with an average age of 75.16 years found in the present sample, in contrast to the average of 70 years in studies found in the literature. In relation to the affected arterial segment, the M1 portion was the main occluded branch (66.67% of cases in the study and 74% in the literature), with a divergence in relation to the frequency of the other segments, as the base article presents the carotid artery internal as the second most affected, but it occupies third place, after the M2 portion, in the present work.

Correspondence: Paulo Victor Santos Machado; Email: paulovictorsmachado@gmail.com.

Background: Hemorrhagic transformation (HT) is a serious complication of ischemic stroke,, especially in patients with large vessel occlusion (LVO), being exacerbated by reperfusion through thrombolytic agents and mechanical thrombectomy. This process occurs due to disruption of the blood-brain barrier (BBB), resulting in blood leakage that increases mortality and morbidity from stroke. Thrombolytic therapy, fundamental in the treatment of stroke, faces the significant challenge of the risk of HT, caused both by the recanalization of the obstructed vessel and by non-fibrinolytic inflammatory mechanisms that weaken the BBB. Radiologically, HT is classified according to the ECASS scale into four types: HI-1 (small areas of petechial bleeding without mass effect), HI-2 (more publicized petechial bleeding), PH -1 (clot with moderate mass effect) and PH-2 (extensive clot with significant mass effect). **Objective:** To analyze the radiological pattern and incidence rate of hemorrhagic transformation in patients undergoing chemical thrombolysis, in the context of ischemic stroke due to large vessel occlusion, in a stroke unity. **Methods:** cross-sectional, observational and retrospective study from the year 2022, carried out by collecting data from patients who suffered HT after chemical thrombolysis in the context of LVO in a stroke unit. Tomographic interpretation was performed using the ECASS scale. **Results:** 35 patients had stroke due to LVO during the study period. Of these, 10 (28.57%) presented HT. Considering this population, 70% were women and 30% men, with a mean age of 66.2 years (range between 39 and 89 years). We used the ECASS scale to quantify HT, obtaining 20% of cases classified as HI-2, 30% as PH-1 and 50% as PH-2. The most affected artery was the M1 branch of the middle cerebral artery (MCA) with 70% of cases, followed by the internal carotid artery with 20% and the M2 branch of the MCA with 10% of cases. **Conclusion:** Hemorrhagic transformation was observed in 28.57% of patients undergoing thrombolysis, standing out as a highly relevant incidence factor for an unfavorable prognosis in stroke. Furthermore, it was revealed that HT occurs more frequently in women and older patients, with an average age of 66.2 years. The most affected segments were the M1 portion of the middle cerebral artery, both right and left, covering 90% of cases. Regarding radiological evolution according to the ECASS criteria, half of the patients were classified at the most severe level of the scale (PH-2), followed by 30% with TH PH-1, showing a predominance of more reserved evolutions.

Incidence of meningitis in bahia from 2013 to 2023: an age group analysis

Jéssica de Andrade Ribeiro Lima[1], Bruna Rafaela Bastos Freire Quixabeira[1], Paulo Vitor Silva Santos[1], Ester Costa Lima[1], Fabrício Rodrigues Barbosa[1], Victor Alex Purificação de Castro Neves[1], Paula Cely da Silva Torres[1], Karollyne de Castro Santos[1], Alexandre David do Nascimento Santos[1], Lucas Granja Kaupert[1]

[1]Universidade do Estado da Bahia, Salvador BA, Brazil.

Correspondence: Ester Costa Lima; Email: ester.enfe@gmail.com.

Background: Meningitis is an inflammation of the meninges, the three membranes that cover and protect the brain and spinal cord. This condition can be caused by various pathogens, including bacteria (such as Neisseria meningitidis and Streptococcus pneumoniae), viruses (such as enteroviruses), and, less frequently, fungi and parasites. Clinically, meningitis manifests with symptoms such as severe headache, high fever, neck stiffness, and photophobia, potentially rapidly progressing to severe cases of sepsis and permanent neurological damage. In Bahia, meningitis represents a significant public health concern, with occasional outbreaks causing alarm among the population. **Objective:** To analyze the incidence of meningitis in Bahia from 2013 to 2023 according to each age group. **Methods:** This is an observational, descriptive, and analytical study, with data collected from confirmed cases reported in Bahia from 2013 to 2023, available in the Notifiable Diseases Information System (SINAN/SUS) as of June 2024. After collecting data according to the ICD-10 chapter on Meningitis in SINAN and population data from the latest demographic census (IBGE), the following analyses were performed according to the demographic variable age group: Incidence rate per 100,000 inhabitants and temporal trend according to the linear regression model using Microsoft Office Excel 2016 software. **Results:** During the analyzed period, 5,740 cases of meningitis were recorded in Bahia, with 24.62% in individuals aged 20 to 39 years, 24.10% in children aged 0 to 4 years, and 15.73% in individuals aged 40 to 59 years. Regarding the meningitis incidence rate in the state, there was a reduction of approximately 54.41% when comparing 2023 with 2013. In turn, the calculation of the incidence rate by age group during the period shows a higher incidence in children aged 0 to 4 years (12.1), followed by children aged 5 to 9 years (5.4), both above the average incidence rate for the period in Bahia (3.5), and a lower incidence in elderly individuals aged 65 to 69 years (0.9). From 2019 to 2020, a decrease in incidence rates was observed, returning to a growth trend in 2022. According to the simple linear regression model, a significant ($p < 0.05$) and decreasing trend in the number of cases over the period was noted, with an average reduction of approximately 1% per year. **Conclusion:** In Bahia, meningitis represents a significant public health concern. The state's health authorities have intensified efforts to control the spread of the disease through vaccination campaigns and case monitoring. Knowing the epidemiological profile and adopting appropriate management are essential to reducing the morbidity and mortality associated with meningitis in the region.

https://doi.org/10.5327/CBN240951

Incidence of stroke in pediatric population in Joinville (Santa Catarina, Brazil)

Maria Eduarda Angelo de Mendonça Fileti[1], Thábata Emanuelle Martins Nunes[1], Yasmin Ramalho Mandarino[1], Henrique Diegoli[1], Carla Heloísa Cabral Moro[1]

[1]Hospital Municipal São José, Joinville SC, Brazil.

Correspondence: Maria Eduarda Angelo de Mendonça Fileti; Email: neuro.mef@gmail.com.

Pediatric stroke can lead to significant mortality and morbidity, with 10-25% of children dying, more than 25% with recurrence and up to 66% with sequelae. Epidemiology in the United States in the last century indicated that acute ischemic stroke varies between 0.6 and 7.9 per 100 thousand children. The study by Lynch (2002), from 1979 to 2000, in the United States, indicated an incidence of 11.9 per 100 thousand children aged between 30 days and 18 years of age, with this number referring to the sum of hemorrhagic and ischemic strokes (4.1 and 7.8). Tsze and Valente (2011) estimated 1.2 to 13 cases per 100 thousand children under 18 years of age. A retrospective observational descriptive study was carried out on the incidence of stroke in the pediatric population in a city in the north of Santa Catarina. Data were collected from the JOINVASC database, a program runned out by the Joinville Municipal Health Department (SMS). Age and gender information was entered into Excel spreadsheets for organized observation of the distribution of total cases. Data were grouped every 2 years and applied to the Poisson distribution. Patients under 18 years of age, of both sexes, were included from January 1, 2010 to July 31, 2019 who had sufficient information in the database. Patients over 18 years of age and/or patients who had not suffered a stroke were excluded from the study. Between 2010-2011: Pediatric population: 319,476, 9 cases of stroke (average of 2.82 cases/100,000 inhabitants. CI 1.29 to 5.35). Between 2012-2013: Pediatric population 316,971, 6 cases of stroke (average 1.89 cases/100,000 inhabitants. CI 0.69 to 4.12). Between 2014-2015: Pediatric population: 315,342, 4 cases of stroke (average of 1.27 cases/100,000 inhabitants. CI 0.35 to 3.35). Between 2016-2017: Pediatric population: 313,889, 6 cases of stroke (average of 1.91 cases/100,000 inhabitants. CI 0.70 to 4.16). Between 2018-2019: Pediatric population: 313,007, 1 case of stroke (average 0.32 cases/100,000 inhabitants. CI 0.01 to 1.78). Our results are in line with data found in the literature, which is still scarce on the subject. New studies are needed to improve care for pediatric stroke victims, considering that risk factors, treatment and prognosis are not the same as for the adult population. A special attention should be given to the pediatric population in order to avoid possible sequelae that will be carried out for an entire lifetime.

Incidental finding of acute disseminated encephalomyelitis in an elderly person: case report

Johnatan Felipe Ferreira da Conceição[1], Gutemberg Augusto Cruz dos Santos[1], Viviane Tavares Carvalho Crelier[1], Nathane Braga da Silva Rezende[1]

[1]Universidade Federal Fluminense, Niterói RJ, Brazil.

Correspondence: Johnatan Felipe Ferreira da Conceição; Email: johnatanfelipe@id.uff.br.

Case presentation: An elderly patient, 68 years old, reported sudden painless hearing loss in the left ear in December 2022. She was seen by an otolaryngologist with suspicion of herpetic infection, and a cranial MRI

was requested along with specific therapy initiation. Treatment with acyclovir began the same week, resulting in significant improvement, although the MRI was only performed on January 16, 2023. She received vaccinations on January 9, 2023, including COVID-19 (bivalent vaccine - Original+Ômicron BA.4/BA.5), measles, mumps, and rubella. The MRI revealed at least six hyperintense lesions on T2/FLAIR, enhanced with contrast, located in the subcortical white matter in the right parietal lobe, lower portion of the left precentral gyrus, right occipital lobe, and periventricular white matter near the temporal horn of the right lateral ventricle. The patient did not present with neurological complaints or other clinical symptoms, and neurological examination showed no significant abnormalities. Laboratory tests were requested, including inflammatory and autoimmune markers, which were unremarkable. Anti-MOG and anti-AQP4 antibodies (CBA method) were also negative. Cerebrospinal fluid analysis showed no significant changes, with 51mg/dL of proteins and negative oligoclonal bands. The overall clinical impression favored a diagnosis of acute disseminated encephalomyelitis (ADEM). Follow-up imaging showed previous lesions less prominently, with some slight contrast enhancement in the subcortical region of the right parietal high convexity, predominantly perivenular. No new lesions were observed, and analysis of the orbits and spinal cord showed no abnormalities. The patient continued clinical follow-up with an expectant approach and underwent regular monitoring exams, remaining asymptomatic with no new clinical complaints. The latest MRI in May 2024 showed no contrast enhancement in the lesions, which were now even less prominent, with no other abnormalities in the neuroaxis. **Discussion:** ADEM is a rare inflammatory demyelinating disease mainly observed in pediatric cases related to vaccines and post-infections. Its occurrence in adults is less frequent, complicating clinical definition and diagnostic criteria. This case presents incidental MRI findings suggestive of demyelination with a monophasic presentation. However, without typical neurological symptoms, but with a temporal relationship with vaccination, which, together with the exclusion of other pathologies, supports the hypothesis of ADEM, highlighting the diagnostic challenge in adults. **Final comments:** This case emphasizes recognizing atypical presentations of rare demyelinating pathologies in adults. A comprehensive clinical history and neurological examination, along with the exclusion of differential diagnoses, are crucial for accurate diagnosis and treatment.

Inclusion body myopathy with dysphagia and its expressive improvement with the use of immunoglobulin

Lorena Fernandes Kronbauer[1], Felipe Leonardo Semensati[1], Fabio Gonçalves[1], Letícia de Barros Dias[1], Lucas de Oliveira Pinto Bertoldi[1], Marcelo Simplicio Carvalho[1], Nathalye Fernanda Pedroso Dircksen[1], Bárbara Okabaiasse Luizeti[1], Mônica Meneguette Silveira[1], Damacio Ramon Kaimen Maciel[1]

[1]Irmandade da Santa Casa de Londrina, Londrina PR, Brazil.

Correspondence: Felipe Leonardo Semensati; Email: felipesemensati@hotmail.com.

Case presentation: Male, 41 years old, with weakness in 4 limbs, without pain, for 3 years, progressively, worse when associated with common clinical decompensations, such as colds and other viral infections. He evolved with moderate dysphagia and restriction to bed. On examination, he demonstrated a generalized loss of strength in the 4 limbs, proximal and distal, with a predominance of the flexor muscles of the fingers, the quadriceps and the extensors of the cervical region, muscle atrophy, without fasciculations, with normal Creatine Phosphokinase, Aldolase and Erythrocyte Sedimentation Rate. Electroneuromyography showing a diffuse myopathic pattern with proximal predominance in the quadriceps. Muscle biopsy demonstrated fiber hypotrophy, liposubstitution, slight endomyosial increase and intracytoplasmic sub-sarcolemic vacuoles. A genetic panel was carried out, without showing any changes. Rheumatological screening showed no changes. There was no improvement in the condition with the use of corticosteroids – so the diagnostic hypothesis was confirmed as Inclusion Body Myositis. Due to associated dysphagia, it was justified to start immunoglobulin at a standard dose, with complete improvement in dysphagia and a significant improvement in limb strength. Patient currently using symptomatic medication and immunoglobulin every 30 days for 4 months until the date of writing this report, maintaining significant improvement. **Discussion:** Inclusion body myositis (IBM) is classified within the idiopathic inflammatory myositis (IIM), a group that also encompasses dermatomyositis, polymyositis and autoimmune necrotizing myositis. Clinically, IBM initially manifests itself with significant weakness in the quadriceps and finger flexor muscles, and is more prevalent in men in a 2:1 ratio. The condition gradually progresses to other muscle groups and, on average, patients lose the ability to walk without assistance within 7 to 10 years after symptoms appear. Furthermore, it can affect the oropharyngeal and esophageal muscles, causing dysphagia. The therapeutic approach to IBM is predominantly empirical due to the limitation of robust clinical studies. Existing literature suggests that IBM tends to be refractory to a range of immunosuppressive agents, including corticosteroids. However, considering the progressive and debilitating nature of the disease, as well as isolated reports of beneficial responses to treatment, with empirical use of rituximab, cyclophosphamide, immunoglobulin, methotrexate, without responses to corticosteroids. **Final comments:** Inclusion body myositis is a disease that is difficult to diagnose, uncommon and has a disabling prognosis. There is generally no good response to treatment, which for now is only empirical with immunosuppressants.

Correspondence: Mariana Hiromi Manoel Oku; Email: mari.hiromi.mo@gmail.com.

Case presentation: A 60-year-old woman presented with generalized muscle weakness and progressive walking difficulty. She had a previous diagnosis of systemic erythematous lupus due to an episode of nephritis in 2006 with a confirmatory renal biopsy. Neurological examination showed mild proximal weakness with normal reflexes and no sensory or bulbar involvement. She had no other systemic symptoms suggestive of lupus activity. Creatine phosphokinase (CK) levels were around 2800U/L and aldolase was 12U/L. Inflammatory markers were low, complete blood count and renal function displayed no abnormalities. Electromyography was compatible with a myopathic pattern. Magnetic resonance imaging (MRI) showed muscle edema in the biceps, triceps, radial extensors, and pronators bilaterally in the upper limbs and in the anterior and medial compartments of the thighs. Prednisone and methotrexate were initiated considering the possibility of an overlap myositis. The patient presented with complete resolution of the weakness after a few months of immunotherapy. However, muscle biopsy displayed rimmed vacuoles, altered mitochondrial activity, and TDP-43 aggregates, besides inflammatory endomysial reaction (with an increase in CD4, CD8, CD68, and MHC-I expression), a pattern indicative of inclusion body myositis. Repeated electromyography showed no myopathy and MRI had significant edema reduction. Post-treatment CK was 80 U/L and aldolase was 2,9 U/L. **Discussion:** Inclusion body myositis (IBM) is a progressive muscle disease with an uncertain pathogenesis. Some authors defend that an autoimmune T-cell-mediated response has a major role in disease development whereas others believe that neurodegenerative mechanisms are more important. Nevertheless, there is a consensus about treatment refractoriness and how the side effects of immunotherapy outweigh its benefits in most cases of IBM. We present a case with a confirmed diagnosis of IBM which fulfilled diagnostic criteria and showed an excellent response to immunosuppression. We hypothesize that this rare evolution can be due to a more prominent inflammatory component in this particular case as it was observed in the patient's muscle biopsy. Additionally, her rheumatological background might also have played a significant role in the favorable response. **Final comments:** Thus, we believe that it is essential to carefully assess IBM cases, evaluating the importance of the inflammatory component in each case to decide if an immunosuppression trial should be performed.

Correspondence: Gabrielle Gomes Garcia; Email: gabriellegarcia3g@gmail.com.

Background: The increasing number of students with disabilities in universities has gained worldwide relevance. When it comes to visually impaired students, teaching morphology becomes a complex process, once visual perception plays an essential role in traditional anatomical knowledge. Neuroanatomy, in particular, is challenging, given the complexity and small size of its structures. Within this context, 3D printing has emerged as an additional tool for the educational inclusion of these students. The 3D printing technology consists of creating a real object from a digital model, which can be adapted in size, shape and texture. **Objective:** Produce and evaluate the applicability of neuroanatomical models created using a 3D printer, with sizes, textures and shapes adapted to the learning of visually impaired students. **Methods:** This is an ongoing experimental study. NOMAD, ZBRUSH and BLENDER software programs were used for three-dimensional modeling of the following anatomical structures: multipolar neurons; spinal cord cross-sections and their tracts; peripheral nerves. The design of the models was based on extensive research into traditional neuroanatomy atlases and textbooks. The 3D models were built using Fused Deposition Modeling (FDM). The materials used were polylactic plastic (PLA) and thermoplastic polyurethane (TPU). Subsequently, the aim of this study is to introduce visually impaired university students to practical neuroanatomy classes, comparing the learning performance of the group that used 3D printed models with the group that did not. **Results:** This project aims to share our experience with creating and using 3D models. We magnified macro and microscopic structures, reaching pieces of about 10 cm. Different three-dimensional planes and varied textures, such as dots and hatches, were used to distinguish white from gray matter and their respective tracts in the spinal

cord segments. Our preliminary experiences with the 3D models reveal that, by bringing the neuroanatomical perception of the visual field into the tactile field, as well as the proportional amplification of the neural structures, spatial understanding by visually impaired students has evolved from an eminently theoretical field to a real and concrete perception. It should also be mentioned that the students' observations and suggestions also guided us in the progressive improvement of the didactic models. Finally, it is worth pointing out that we are still working on a definitive model in order to understand, statistically, the effectiveness of these models in neuroanatomy classes. **Conclusion:** The neuroanatomy models produced by the 3D printer can be a tool for the inclusion of students with and without visual impairments, improving their understanding and learning. However, more studies and evaluation methods are needed to quantify the real impact of these pieces.

Infantile cerebral venous thrombosis associated with basal ganglia hemorrhage due to protein's deficiency: case report

Clara e Silva Modesto[1], Luana Marcondes Emergente Caproni[1], Renato Ortolani Marcondes de Castro[1], Marcelo Massote de Toledo[2]

[1]Universidade José do Rosário Vellano, Alfenas MG, Brazil.
[2]Universidade do Vale do Sapucaí, Pouso Alegre MG, Brazil.

Correspondence: Clara e Silva Modesto; Email: modestoclara07@gmail.com.

Case presentation: A one-year-old female patient sought medical care due to cephalea associated with projectile vomiting and diarrhea. She had a progress in her condition with changes in level of consciousness, motor deficit and second stage of dehydration after bacterial tonsillitis, she has started treatment with amoxycillin and ceftriaxone 5 days ago. Scans have been conducted, including a cranial computed tomography (CT), which found a cerebral venous thrombosis (CVT) in cavernous sinus, straight sinus, transverse sinus and left great cerebral vein and basal ganglia hemorrhage. Laboratory tests: Hemoglobin (Hb): 10.9; Hematocrit (Ht): 32.7%; Total Iron-Binding Capacity (TIBC): 77.3; RDW: 14.7; Platelets: 700,000; Total Leukocytes: 13,500 (1% Rod cells, 79% Segmented Neutrophils, 15.4% Lymphocytes); C-Reactive Protein (CRP): 32.5; Amylase: 13; Blood Glucose: 137; Potassium (K+): 5.2; Sodium (Na): 135; AST: 51; ALT: 52. Heparinization was performed and patient was hospitalized in Intensive Care Unit, evolving with an improvement of the condition, and then she was discharged after 13 days, when she had no sequela. The patient was guided to continue treatment and was referred to a specialist to investigate the cause of thrombosis, when protein S (PS) deficiency was checked, after laboratory tests performed on February 11, 2010 (PS: 30%). **Discussion:** CVT is a rare subtype of stroke and has an estimated incidence of 1.32 per 100,000 people. About 20% to 30% of the cases are related to genetic factors, and PS deficiency is the main factor and the most difficult to be diagnosed, being found in 1.5 to 7% of the thrombophilic patients. This deficiency is characterized by a defect on PROS1 gene, whose function is crucial when binding to protein C, conducting degradation in the coagulation factors Va and VIIIa. **Final comments:** Mortality rate of CVT can vary from 5 to 30%, but it has some mortality predictors or unfavorable prognosis such as change in level of consciousness and cerebral hemorrhage. The condition in children has a better prognosis, once their brain has a greater neuroplasticity. Thus, we highlight that treatment success comprises a multidisciplinary team and a specialized medical care follow-up.

Infection sites most associated with the occurrence of delirium during hospitalization in a stroke unit: a cohort study in a reference hospital in Bahia

Maria Eduarda Messias Vassoler[1], Gabriel Souza Medrado Nunes[1], Milena Fernandes de Oliveira[1], Gabriel Teles de Oliveira Piñeiro[1], Luiz Paulo Oliveira Martins[1], Thaís Barbosa de Oliveira[1], João Pedro Fernandes Gonçalves[1], Alex de Cerqueira Silveira Figueiredo[1], Antonio Lázaro Santos Soares Junior[1], Pedro Antonio de Jesus[2]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.
[2]Hospital Geral Roberto Santos, Salvador BA, Brazil.

Correspondence: Maria Eduarda Messias Vassoler; Email: maria.vassoler@ufba.br.

Background: Delirium is a clinical syndrome linked to various short- and long-term complications in stroke patients. Among many predisposing factors, infections are highly associated with delirium during hospitalization. However, there is still a lack of comprehensive research on the association between the occurrence of infection sites and delirium in hospitalized stroke patients. **Objective:** To investigate the association between infection sites and the occurrence of delirium in stroke patients. **Methods:** This study enrolled patients with acute stroke admitted to a stroke unit at a referral hospital in Bahia, between July/2023 and March/2024. Clinical and epidemiological characteristics were extracted from patients' medical records or obtained through personal interviews. Infection was defined as the administration of antibiotics or documented infection noted in medical records. Delirium was assessed using the CAM-ICU scale, conducted by trained researchers. The chi-square test was employed to ascertain associations, and odds ratios with confidence intervals were derived through logistic regression. **Results:** The study comprised 213 patients, of whom 51.2% were female, with a median age of 66.3 years (IQR: 59-74.3). Within this cohort, 66.7% lacked a completed high school education. Regarding comorbidities, 36.2% had diabetes, 78.95% had hypertension, and 27.7% had dyslipidemia. Delirium occurred in 47 patients (22.1%) at least once during hospitalization. Infection was diagnosed in 95 patients (44.6%), with respiratory infection diagnosed in 34 (35.8%), urinary infection in 53 (55.8%), skin infection in 6 (6.3%), bloodstream infection in 3 (3.2%), other types of infection in 10 (10.5%), non-specified infection in 37 (38.9%), and 38 patients (40%) had more than one type of infection during the hospitalization time. The presence of infection during hospitalization was significantly associated with delirium occurrence ($p<0.001$). Among different infection sites, respiratory tract infection exhibited the strongest association with delirium risk ($p<0.001$; OR: 4.1; 95% CI: 1.8 - 9.4), followed by urinary tract infection ($p<0.05$; OR: 2.6; 95% CI: 1.2-5.4). The presence of multiple infection sites was not more associated with delirium than single sites ($p>0.05$). **Conclusion:** In our study, the respiratory tract was the infection site most associated with delirium, while urinary tract infection was the second. The presence of more than one site of infection was not more associated with delirium. However, more studies are needed to better understand these associations.

Inflammatory polyneuropathy in the state of São Paulo: a comparative analysis of of the pre-pandemic and post-pandemic period

Aline Marques Barreto Scalioni[1], Maria Luiza Nunes Guimarães[2], Camila Variani[3], Thaís Rigon[4], Fernanda Oliveira Fonseca[5]

[1]Universidade Nove de Julho, Guarulhos SP, Brazil.
[2]Universidade de Franca, Franca SP, Brazil.
[3]Universidade Luterana do Brasil, Canoas RS, Brazil.
[4]Atitus Educação, Passo Fundo RS, Brazil.
[5]Instituto Universitário de Ciências de La Salud Fundacion H. A Barceló, Capital Federal, Argentina.

Correspondence: Aline Marques Barreto Scalioni; Email: alinemscalioni@gmail.com.

Background: Acute inflammatory polyneuropathy is an inflammatory demyelinating neuropathy that affects peripheral nerves. It is characterized by muscle weakness, impairment of reflexes and tactile sensitivity, associated with increased levels of proteins in cerebrospinal fluid. It is a treatable, yet under diagnosed, condition, that affects 1 child in 200,000 and at least 1 to 2 adults in 100,000. **Objective:** To analyze the cases of inflammatory polyneuropathy in the pre-pandemic and post-pandemic periods. **Methods:** This is an ecological, descriptive, and observational study with a quantitative approach. Data were obtained from the Department of Informatics of the Unified Health System (DATASUS), through the TABNET platform, extracting information about the incidence of hospitalizations for inflammatory polyneuropathy in the state of São Paulo from 2018 to 2024, as well as its mortality. The population analyzed includes individuals regardless of age, and the variables analyzed were the month and year of hospitalization. **Results:** From the years of 2018 to 2024, São Paulo had 4,474 hospitalizations for inflammatory polyneuropathy, with 2023 (the last year of the COVID-19 pandemic according to the World Health Organization) having the highest number of hospitalizations (n=922) (about 20.6% of the total). March of 2023 had the highest number of cases (n=97). Analyzing the cases in relation to the pre-pandemic and post-pandemic periods of COVID-19, the years of 2018 and 2019 had 682 and 759 cases, respectively, with a decline in the initial pandemic years, 2020 and 2021, respectively 558 and 629 hospitalizations, which can be due to underreporting of cases. Numbers increased again in the years of 2022 to 2024, with 847 cases in 2022, 922 in 2023, and 77 hospitalizations up to February 2024. After analyzing the results, there was a 28.2% increase in registered cases of polyneuropathy comparing the pre-pandemic and post-pandemic years. Further studies are required to confirm these findings, but a potential relationship has been observed between these pathologies and the immunological side effects associated with COVID-19. **Conclusion:** The findings of this study concluded that the number of notified inflammatory polyneuropathy cases in the years 2022 and 2023, after the pandemic, increased by a difference of 335 cases, compared to the years of 2018 and 2019, before the pandemic. It can be related to the reporting of some cases of Guillain-Barré syndrome after COVID-19 infection (still requiring further studies for certified correlation). One of the limitations of this study was the exclusive use of the DATASUS database

https://doi.org/10.5327/CBN240959

Influence of gender on IBM: analysis of epidemiological and clinical characteristics

Bruna Moreira de Souza Proença[1], André Macedo Serafim da Silva[1], Ana Lucila Moreira[1], Cristiane de Araújo Martins Moreno[1], Eliene Dutra Campos[1], Mariana Cunha Artilheiro[1], Tatiana Ribeiro Fernandes[1], Rodrigo Holanda Mendonça[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Bruna Moreira de Souza Proença; Email: brunamsproenca@gmail.com.

Background: Inclusion Body Myositis (IBM) is the most common acquired myopathy in individuals older than 50 years. The disorder is slowly progressive, and response to therapies has generally been poor. Clinical heterogeneity may influence treatment responsiveness; however, data

regarding heterogeneity in IBM are limited and often conflicting. Disease progression has been related to the age of onset, with faster progression when the age of onset is more advanced. A recent study revealed that female and black patients have distinct clinical phenotypes. Gender differences may play a role in the variability of clinical severity and progression. **Objective:** To describe epidemiological and clinical characteristics of IBM patients, and to investigate the relationship between disease duration and clinical severity with a focus on gender differences. **Methods:** We evaluated a cohort of IBM patients (6 males, 8 females) from a center of neuromuscular diseases in Brazil using clinical assessments, IBM Functional Rating Scale (IBMFRS), and Motor Function Measure (MFM32). To compare variables between genders and assess the relationships between disease duration and severity, we performed statistical analyses, including Mann-Whitney tests, Pearson correlations, and interaction regressions. **Results:** The median age at onset was 49.5 years for males (45.0 - 66.8) and 51.0 years for females (45.3 - 58.5). The median time to diagnosis was 4.5 years for males (3.3 - 9.0) and 2.5 years for females (1.0 - 4.8). The median disease duration was 7.5 years for males (4.3 - 12.5) and 9.5 years for females (5.8 - 13.8). The median IBM-FRS score was 28.5 for males (20.8 - 34.8) and 31.0 for females (22.0 - 36.5), with no significant difference. Disease duration significantly impacted IBM-FRS scores, reducing by approximately 1.176 points per year (B=-1.176, p<0.001). Gender did not significantly influence the IBM-FRS score (T=-0.128, p=0.901). The median MFM scores for 9 patients showed no significant difference: males had 65.8 (16.1 - 91.7) and females had 67.7 (40.6 - 92.2) (p=0.624). Mobility status varied slightly: 62.5% of females and 50% of males ambulated without support, with no significant association between gender and mobility status (χ^2=0.271, p=0.873). **Conclusion:** Our study indicates no significant differences between male and female IBM patients in terms of epidemiological and clinical data. While disease duration significantly impacts severity, gender does not. As research suggests some differences between genders, future comparisons should investigate other clinical, laboratory, and biopsy characteristics. Further research with larger sample sizes is needed to confirm these findings and explore the underlying mechanisms affecting IBM progression.

[2]Universidade do Sul de Santa Catarina, Tubarão SC, Brazil.

Correspondence: Fabrício Weinheimer Lippert; Email: fabriciowlippert@gmail.com.

Background: Studies reveal that the established peripheral immunosuppression in cases of ischemic stroke may make survivors susceptible to infections. Furthermore, ischemic stroke is increasingly associated with impairment of the intestine-brain axis. **Objective:** To show intestinal permeability as well as indications of peripheral immunosuppression using a preclinical model of ischemic stroke. **Methods:** We divided the animals into two groups: 1) Sham and 2) middle cerebral artery occlusion (MCAO). We evaluated the neurological score, weight, and temperature at 3 h, 24 h, and 48 h after MCAO. After 72 hours of MCAO, we induced painless death in the animals and removed blood through cardiac puncture to assess intestinal permeability, total cell count, body weight, spleen weight, temperature, and neurological score. **Results:** In animals subjected to MCAO, intestinal permeability and blood cell count increased compared to the sham group. There was a significant decrease in weight in all groups within 72 hours after MCAO and sham. A neurological score revealed a cognitive decline in the initial hours after MCAO, but this decline reversed in the following days. There was a decrease in spleen weight, such as in the spleen weight/animal weight ratio in the MCAO group. **Conclusion:** We conclude that ischemic stroke due to MCAO can lead to an increase in intestinal permeability and peripheral immunosuppression in rats.

In-hospital mortality rate due to meningitis in Brazil, from 2008 to 2022: a joinpoint analysis

Emmanuel Santos Trindade[1], Priscila Santos Oliveira[1], Philip George Glass Andrade[1], Davi Tanajura Costa[1]

[1]Universidade Estadual do Sudoeste da Bahia, Vitória da Conquista BA, Brazil.

Correspondence: Gustavo Alves Cangussú; Email: canguss.gustavo@gmail.com.

Background: Meningitis, despite public health efforts to reduce its incidence through vaccination against N. meningitidis, S. pneumoniae and H. influenzae, continues to present significant lethality, reaching up to 54% in low-income countries. **Objective:** To analyze the in-hospital mortality rate due to meningitis in Brazil, from 2008 to 2022. **Methods:** This is an ecological time series study of the in-hospital mortality rate due to meningitis in Brazil, stratified by sex, ethnicity and age group. Data on hospitalizations for meningitis from the Hospital Information System (SIH) were used, recorded by ICD-10 codes A17.0, A32.1, A39.0, A87, B00.3, B01.0, B02.1, B05.1, B26.1, B37.5, B38.4, G00, G01, G02 and G03. A temporal analysis was carried out using a joinpoint regression model, through which the Annual Percent Change (APC) and Average Annual Percent Change (AAPC) were obtained with 95% Confidence Interval (95% CI). A p value ≤ 0.05 was considered statistically significant. **Results:** The in-hospital mortality rate from meningitis in Brazil from 2008 to 2022 was 66.12 deaths/1000 hospitalizations. Mortality was higher in females (67.00 deaths/1000 hospitalizations) than in males (65.48 deaths/1000 hospitalizations). The ethnicities in decreasing order of mortality are indigenous (123.60 deaths/1000 hospitalizations), black (98.28 deaths/1000 hospitalizations), brown (70.33 deaths/1000 hospitalizations), yellow (70.10 deaths/1000 hospitalizations) and white (61.86 deaths/1000 hospitalizations). There is a directly proportional relationship between age and mortality rate, ranging from 29.27 deaths/1000 hospitalizations in the 0-9 years age group to 324.88 deaths/1000 hospitalizations in the ≥ 80 years age group. The mortality rate showed an increasing trend (AAPC: 4.26 [2.48; 6.06)]; p:<0.001). This trend was followed by males (AAPC: 4.57 [3.07; 6.10]; p:<0.001) and females (AAPC: 3.84 [1.52; 6.22]; p:0.003). White (AAPC: 4.32 [2.00; 6.70]; p:0.001) and brown (AAPC: 4.60 [2.30; 6.95]; p:<0.001) ethnicities showed an increasing trend. The other ethnicities in turn showed a stationary trend. The age groups of 10-19 years (AAPC: 4.44 [2.87; 6.03]; p:<0.001), 20-29 years (AAPC: 3.61 [0.52; 6.79]; p:0.03) and 50-59 years (AAPC: 2.76 [0.01; 5.58]; p:0.05) showed an increasing trend. The other age groups showed a stationary trend. The 0-9 years age group presented 2 joinpoints, characterizing a decreasing trend from 2008 to 2013 (APC: -10.90 [-13.93; -7.75]; p:<0.001) and a stationary trend both from 2013 to 2016 (APC: 16.31 [-0.40; 35.82]; p:0.055) and from 2016 to 2022 (APC: -1.12 [-3.68; 1.51]; p:0.34). The ≥80 years age group presented a joinpoint in 2010, but characterized a stationary trend in both determined periods. **Conclusion:** Based on the results, it is clear that in-hospital mortality due to meningitis in Brazil showed an increasing trend, mainly among white and brown ethnicities, young adults and middle-aged people.

Initial neurological manifestations of cryptococcosis in non-HIV adults

Flavia Ana Pacheco[1], Renata Cicci Cunha Castro[1], Bárbara Rodrigues Amaral de Oliveira[2], Ruth Maria Ribeiro Guerra[1]

[1]Universidade de Uberaba, Uberaba MG, Brazil.
[2]Centro Universitário de Brasília, Brasília DF, Brazil.

Correspondence: Flavia Ana Pacheco; Email: flavia.ana.pacheco@gmail.com.

Background: Cryptococcus is an opportunistic yeast with an immunoprotective polysaccharide capsule possessing immunomodulatory properties, which predisposes the organism to neurotropism. The primary infection occurs in the lungs through inhalation of the pathogen, predominantly affecting immunocompromised individuals. It can present asymptomatically or more commonly as meningoencephalitis and pulmonary forms. In immunocompetent individuals, meningoencephalitis is the main presentation. **Objective:** To describe the most frequently presented initial neurological manifestations in non-HIV adults with cryptococcosis. **Methods:** A systematic literature review was conducted with the guiding question: "What are the most frequently presented initial neurological manifestations of non-HIV adults with cryptococcosis?" The Pubmed database was used to search for studies using the descriptors: Cryptococcosis, Neurologic Manifestations, Neurologic Examination and HIV, with the help of Boolean operators "AND", "OR" and "NOT". Articles published between 2019 and 2024 were included and those evaluating cryptococcosis in HIV patients, studies conducted on individuals under 18 and over 65 years and studies not reporting the initial clinical neurological manifestations were excluded. **Results:** The final sample consisted of 19 articles, including 18 case reports and one case-control study with 270 patients, totaling an N of 288. In total, 35 types of neurological alterations were identified, with each article citing between one and nine alterations. Headache was the most frequent manifestation, present in 158 patients (54.7%), followed by meningeal signs in 59 patients (20.4%), decreased auditory acuity in 7 patients (2.5%) and fever in 6 patients (2%). Among the less frequent alterations cited in 2 patients (0.7%) were cognitive alterations, photophobia, nausea, diplopia, ptosis, gait disturbance, altered mental state, seizures, vomiting, visual disturbance, papilledema and ocular movement limitation. Finally, among the alterations reported in 1 patient (0.3%) were tinnitus, dizziness, hemiballismus, blurred vision, ocular deviation, mydriatic pupil, non-reactive pupil, slowed reasoning, altered consciousness level, balance disturbance, retro-orbital pain, lacrimation, hemichorea, confusion, decreased facial sensitivity, facial mimic alteration and dysarthria. **Conclusion:** Cryptococcosis in non-HIV patients is a condition with a challenging early diagnosis. The most common neurological manifestations of the disease include headache, meningeal signs, decreased auditory acuity and fever. Identifying the initial neurological alterations presented in the disease can help guide the diagnostic reasoning towards cryptococcosis in differential diagnosis and direct early treatment for a better prognosis.

Integrating objective and subjective data in a new outcome scale for epilepsy surgery in people with severe epilepsies (PWSE): the Porto Alegre seizure impact scale (PASIS)

André Palmini[1], Eliseu Paglioli[1], Rafael Paglioli[1], William Martins[1], Fernanda Schuh Martins[1], Thomas Frigeri[1], André Gus[1], Victoria Bizzi Schvartzman[1], Natalie Donida[1], Bibiana Thomé[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Victoria Bizzi Schvartzman; Email: bizzivictoria@gmail.com.

Background: Significant improvement with epilepsy surgery in PWSE -despite seizure persistence- includes shorter and milder seizures, or no longer needing frequent ER visits because of prolonged TCS. These post-op gains beyond complete seizure freedom POSITIVELY IMPACT the lives of PWSE but are not captured by objective outcome scales focused on degree of seizure control, such as the Engel and ILAE outcome scales. **Objective:** Here we propose a new scale -the PASIS- which is more relevant for PWSE in whom seizure freedom is unlikely, yet surgery may bring significant improvement. **Methods:** The PASIS integrates objective and subjective data both pre and post-operatively, considering changes in frequency, severity, duration and circadian distribution of seizures and post-ictal abnormalities, as well as the global impression of the effectiveness of surgery for the life of the patient and the family. PASIS scores are a sum of points from each category and the higher the score the worse the outcome. Subjective items may decrease or increase final scoring. Subjective scores are -1 when there was improvement, +1 when that feature was like before operation and +2 if worse. Thus, when the impact of the operation is minimal, post-op PASIS scores increase. Difference between post- and pre-op scores lead to a 4-tiered outcome classification: 5 or more points less, PASIS 1 (patient much improved); 1 to 5 points less, PASIS 2 (improved); equal scores, PASIS 3 (similar condition); bigger than pre-op score, PASIS 4 (worse). **Results:** Illustrative case: 17-month-old boy with infantile spasms evolved with severe multifocal epilepsy, many daily generalized seizures, protracted post-ictal somnolence and psychomotor regression. There was mild right hemiparesis and bilateral gyral abnormalities yet a gross abnormal area, resembling polymicrogyria, in the left frontal lobe. EEGs had diffuse abnormalities and independent trains of spikes and high amplitude slow waves over one or the other hemisphere, predominating in the left frontal lobe. Pre-op PASIS was 13 (generalized seizures with sudden falls (head drop) = 4 points; daily seizures (≥5/day) = 5 points; seizures also during wakefulness = 2 points; and protracted, disabling post-ictal changes = 2 points). Resection under acute ECoG removed the lesion on the left frontal lobe. 12 months later, the boy is walking and interacting, still with daily seizures, but mild and brief. With no post-ictal. He is Engel IV – but his PASIS went from 13 pre-op to 5 post-op; FINAL PASIS = 1 (much improved), reflecting significant gains despite seizure persistence. **Conclusion:** PWSE suffer from frequent seizures that can lead to recurrent ER visits and protracted post-ictal disability. Many have surgically remediable epilepsies that although responding partially to surgery lead to significant improvements in daily life, not captured by scales focused solely upon degree of seizure control and thus a new scale is proposed to gauge the effect of surgery in this population.

https://doi.org/10.5327/CBN240964

Intellectual disability and neuropsychomotor delay in a patient with a rare variant 49,XXXXY of Klinefelter syndrome

Viviane Müller[1], Maria Fernanda Peruci Felippe[1], Christian Camatti Menegon[1], Vitor Ritt Xavier[1], Lara Willers Lobato[1], Maria Eduarda Friedrich Pfeifer[1], Maria Eduarda Corrêa Pereira[1], Aline Deborah de Moraes[1], Rafaela Gageiro Luchesi Soares[1], Rafael Fabiano Machado Rosa[1]

[1]Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Viviane Müller; Email: viviane.muller@ufcspa.edu.br.

Case presentation: The patient was the first child of a young couple. During pregnancy, intrauterine growth restriction was diagnosed in the seventh month. He was born at term, by vaginal delivery, weighing 1950 grams, measuring 43 centimeters, and with an Apgar score of 9 at the fifth minute. At birth, Down syndrome was considered as a diagnosis. Cardiological clinical evaluation revealed a probable pulmonary stenosis. Regarding neuropsychomotor development, he experienced delays, sitting without support at 8 months and walking alone at 3 years and 1 month. At 3 years and 9 months, he was able to pronounce a few words. He later presented learning difficulties. Hand and wrist radiography showed significant bone maturation delay. Physical examination revealed flattening of the occipital skull; low anterior and posterior hairline; upslanting palpebral fissures; posteriorly rotated ears with overfolded helix; high arched palate; retractile testes and small penis hidden in the pubic fat. Karyotyping revealed the presence of a male chromosomal constitution with X chromosome tetrasomy - 49,XXXXY - which was compatible with the diagnosis of Klinefelter syndrome variant. Endocrinological evaluation confirmed the presence of hypergonadotropic hypogonadism. **Discussion:** Reports of variants of Klinefelter syndrome are considered rare. We emphasize the challenge of diagnosing these variants based on clinical findings, given the overlap with those of other chromosomal abnormalities. Therefore, karyotyping is essential for the etiological definition of the syndrome and, consequently, the appropriate management of the patient. **Final comments:** With this report, we highlight the importance of considering variants of Klinefelter syndrome, such as 49,XXXXY, in individuals with neuropsychomotor delay and intellectual deficit, presenting with dysmorphic features and hypogonadism.

Background: Intracerebral hemorrhage (ICH) is often complicated by elevated blood pressure (BP), increasing the risk of persistent and recurrent hemorrhage, disability, and death. Numerous research initiatives have yielded divergent results concerning BP management, leading to uncertainty, particularly regarding the influence of treatment timing and the optimal BP target. **Objective:** To perform a systematic review and updated meta-analysis comparing the impact of intensive BP lowering versus standard BP lowering in ICH patients. **Methods:** We searched PubMed, Embase, and Cochrane databases for randomized controlled trials (RCT) comparing intensive BP lowering, commonly defined as BP<140 mmHg, to standard treatment in ICH patients. The protocol was registered on PROSPERO (CRD42024552587). A pooled analysis was conducted to evaluate good functional outcome (defined as a modified Rankin Scale (mRS) score of 0 to 2), major disability or death (mRS score of 3 to 6), all-cause mortality, and substantial hematoma growth. Subgroup analyses examined differences in outcomes concerning studies in which only the intervention group maintained target BP levels below 140mmHg, and according to time-to-treatment (before or after 6 hours from the onset of ICH). Statistical analysis was performed using RevMan 5.4.1. Heterogeneity was assessed with I^2 statistics. **Results:** We included 11 RCTs with a cohort of 13.604 patients, of whom 6.743 (49.56%) underwent intensive BP lowering. Intensive treatment was associated with a reduction in major disability or death (RR=0.93; 95% CI=0.90-0.96; p<0.001; I^2=0%), all-cause mortality (RR=0.86; 95% CI=0.79-0.94; p<0.001; I^2=0%) and substantial hematoma growth (RR=0.83; 95% CI=0.73-0.95; p=0.008; I^2=18%) compared to the standard group, while good functional outcome showed no statistically significant difference (RR=1.08; 95% CI=0.99-1.18; p=0.08; I^2=53%). In the subgroup analyses, there were no statistically significant differences in any outcomes related to studies in which only the intervention group maintained target BP levels below 140mmHg or according to time-to-treatment. **Conclusion:** Our findings suggest intensive blood pressure lowering management in intracerebral hemorrhage patients reduces major disability or death, all-cause mortality, and substantial hematoma growth in comparison to standard treatment.

Interferon gamma, IL-18 and NFL as potential biomarkers for COVID-19 severity and lethality

Helena França Alcaraz Ferreira[1,2], Isabela Stornelli Teixeira[2], Andreza Salvio Lemos[2], Renan Amphilophio Fernandes[2], Carlos Henrique Ferreira Ramos[1], Carlos Henrique Ferreira Ramos Filho[3], Wagner Luís da Costa Nunes Pimentel Coelho[4], Luciane Almeida Amado Leon[4], Soniza Vieira Alves-Leon[1,2]

Patients infected with SARS-CoV-2 may experience different disease manifestation based on factors like age, sex, comorbidities and the host's immune integrity. Its pathophysiology has been contemplated as a complex web of cell signaling pathways and systemic consequences, presenting the risk of hospitalization and the manifestation of severe symptoms. Aggravated pro-inflammatory cytokine response has been associated with lethality and extensive lesions. Thus, this study aims to investigate the relation between the levels of interleukin-18 and interferon gamma (IL-18, IFN-y), neurofilament light chain (NfL) and disease outcome in patients with acute COVID-19. In order to analyze these biomarkers, peripheral blood was collected, and plasma was examined accordingly. A cohort of 32 acute severe COVID-19 patients, critically ill, was investigated. Statistical analysis was performed using Kruskal Wallis and Mann Whitney U test. This cohort was compared to its homologous healthy control group. Regarding data evaluation, the SIMOA platform was used for NfL, while the cytokines were analyzed using the Luminex 200 system. Our results showed that there were statistically significant differences in NfL (p<0.0001), IFN-y (p=0.0230) and IL-18 (p=0.0014) IFN-y levels (p=0.0056) between severe COVID-19 cohort and healthy control group. When we deeper analyze the severe COVID-1 group, we divide them according to the outcomes: Deceased and Survivor. For those, we also found that NfL (p<0.0001), IFN-y (p=0.0056) and IL-18 (p=0.0008) levels where significantly higher in the deceased sub-group when compared to survivor group.

It has been corroborated that a dysregulated immune response leads to tissular impairment and, in turn, worsening of patient condition. Also, NfL levels may play an important role as a biomarker of cognitive impairment and neurological manifestations associated to disease severity and lethality in COVID-19. For that reason, it may be of interest to explore those biomarkers in larger cohorts as they possibly may be important prognostic tools for COVID-19 positive patients, aiming for a more precise and faster clinical evaluation and, consequently, appropriate treatment.

Interleukin-6 inhibitors in neuromyelitis optica spectrum disorder: a systematic review and meta-analysis

Giovani Noll[1], Marcos Madeira de Lima[1], Viviana Konzen[1], Alessandro Finkelsztejn[1]

[1]Hospital de Clínicas de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Giovani Noll; Email: nlgiovanimdr@gmail.com.

Background: Interleukin-6 (IL-6) inhibitors recently emerged as a promising therapy in neuromyelitis optica spectrum disorder (NMOSD). A few comparative studies assessing its efficacy and safety are currently available. **Objective:** To perform a systematic review and meta-analysis of efficacy and safety endpoints comparing IL-6 inhibitors to placebo or traditional immunosuppressants in patients with NMOSD. **Methods:** We searched PubMed, Embase and Cochrane Central for studies comparing IL-6 inhibitors to alternative therapies in patients with NMOSD. Efficacy endpoints included hazard ratio for relapse and annualized relapse ratio (ARR). Safety outcomes included any adverse event and infection. Statistical analysis was performed using RevMan Web (Cochrane Collaboration) and R package meta. Heterogeneity was assessed with I^2 statistics. **Results:** 4 studies were included (3 randomized controlled trials and 1 retrospective cohort), comprising 361 patients (228 treated with IL-6 inhibitors) with a mean follow-up time of 20.19 (±7.04) months. Mean age was 45 (±13.54) years, 316 (87.53%) were female and 276 (78.45%) had detectable serum anti-aquaporin-4 antibodies. At baseline, mean duration of disease was 5.12 (±3.68) years, mean EDSS was 4.34 (±1.32) and mean ARR was 1.73 (±1.07). Hazard ratio for relapse (hazard ratio 0.35; 95% CI 0.23 to 0.55); p<0.00001; I^2=0%) and ARR (mean difference -0.79 relapses/year; 95% CI -1.54 to -0.03; p=0.04; I^2=96%) were significantly reduced in patients treated with IL-6 inhibitors when compared to those treated with placebo or traditional immunosuppressants. No significant difference was found in any adverse event (odds ratio 1.10; 95% CI 0.67 to 1.79; p=0.71; I^2=0%) and infection (odds ratio 1.59; 95% CI 0.45 to 5.63; p=0.48; I^2=48%) between the treatment groups. Statistically significant results in efficacy endpoints were restricted to IgG-aquaporin-4 seropositive subgroup of patients. **Conclusion:** This meta-analysis indicates that IL-6 inhibitors are superior to placebo and traditional immunosuppressants in reducing relapses in patients with aquaporin-4 seropositive NMOSD, without increasing adverse events or infection rates.

Amyotrophic lateral sclerosis (ALS) is a rare neurodegenerative disease considered complex due to its heterogeneity. Despite being known for many years, few countries have precise information about its epidemiology and the characteristics of individuals diagnosed with ALS. In Brazil, the lack of information about ALS limits the use of data for advancing research and developing public policies that benefit people affected by this health condition. In this context, the objective to present the development of a platform for the management and monitoring of ALS in Brazil in order to provide intrinsic and timely data to support the formulation of public policies while simultaneously improving the care and monitoring of ALS patients. The development of this platform was supported by the Ministry of Health of Brazil. It was conceived in response to the needs identified in the epidemiological scenario related to the disease, as well as the limitations reported by health professionals specialized in treating ALS patients. The developed platform consists of two systems: the Brazilian National ALS Registry, responsible for collecting structured epidemiological data from ALS patients throughout Brazil; and the Electronic Medical Record for ALS patients, responsible for assisting in the multidisciplinary monitoring of ALS patients safely and appropriately, based on the Clinical Protocols and Therapeutic Guidelines (in Portuguese, Protocolos Clínicos e Diretrizes Terapêuticas - PCDT) for ALS. The systems were developed to be interoperable and capable of securely and effectively exchanging information, considering the security and privacy of patient data in accordance with the General Data Protection Law (in Portuguese, Lei Geral de Proteção de Dados - LGPD). The integration of surveillance and monitoring data presents significant benefits for the development of public policies and the planning of strategies at all levels of health care, in addition to providing a realistic view of the country's situation regarding ALS cases. Therefore, this platform is being used as a tool for research, intervention, monitoring, and strengthening the response to ALS within the Brazilian Unified Health System (in Portuguese, Sistema Único de Saúde - SUS).

Correspondence: Emanuel de Assis Bertulino Martins Gomes; Email: emanueldeassis@alu.ufc.br.

Background: Stroke is a serious and disabling disease all over the world. It is a serious medical emergency and reperfusion therapies have been developed with increasing technology in recent years. However, treatment is not offered equally in all regions of the world, including Brazil, where there are marked differences in access to healthcare between different regions. **Objective:** To propose a method for georeferencing and mapping the characteristics of stroke in Ceará state, Brazil, using as an initial analysis the distance and travel time profile between the municipal hospitals in the state and a Stroke Unit located in the capital. **Methods:** Choropleth maps were constructed with R software for statistical analysis, using the "gmapsdistance" package, which estimates the distances between the territories on the geographic map. The geolocation data was obtained from Google Maps. To continue the project, data will be collected from reference hospitals in Ceará, both on the sociodemographic nature/comorbidities of the participants and on stroke characteristics, such as the time of symptom onset and treatment time, scales at hospitalization and discharge (e.g. NIHSS and ASPECTS) and clinical outcomes. A database will be created to assess the profile of stroke care in Ceará, including distances and treatment times. With this data, the extent of stroke in the state and the effectiveness of medical care for those patients will be evaluated. **Results:** Travel time and distance estimates were made between the hospitals in the state's municipalities in relation to the Stroke Unit at the Fortaleza General Hospital (HGF), which is a reference in tertiary care in Ceará for stroke patients. It was observed that the average travel time to the HGF varied between 0.3 and 8 hours, not exceeding the limits for treatment in certain circumstances by indication. The distance profile showed a maximum mean distance of 500 kilometers and a minimum of 5 kilometers between those locations. As the HGF is the only hospital that performs mechanical thrombectomy on an emergency basis in the state, the results described also reflect the disparity in access to this procedure. **Conclusion:** The study presents a method of mapping stroke characteristics in Ceará, Brazil, shedding light on the disparities in access to timely stroke treatment. Using choropleth maps and geolocation data, we identified variations in travel time to the Stroke Unit of the HGF, the sole facility offering thrombectomy in Ceará. Our findings reveal that while some areas have access within acceptable timeframes, others face significant delays, highlighting the need for equitable distribution of stroke care resources. By understanding the geographical profile of stroke care, policymakers and healthcare providers can better allocate resources to ensure prompt treatment and improve outcomes for stroke patients across the state.

Background: Interventional neuroradiology is a subspecialty dedicated to the diagnosis and treatment of cerebrovascular diseases and nervous system tumors. It combines neurosurgical and neuroradiological knowledge, enabling minimally invasive techniques. **Objective:** To investigate the epidemiological profile and clinical outcomes of patients at an interventional neuroradiology service in southern Santa Catarina. **Methods:** Cross-sectional analytical observational study with a quantitative approach and primary and secondary data collection. The study population consisted of all patients undergoing

interventional neuroradiology at a hospital in southern Santa Catarina who were followed up at Clínica Neurosul Neuroespecialistas from January 2017 to July 2022, with a sample of 242 patients. Patient profiles, underlying disease characteristics, and clinical outcomes were evaluated. Secondary data were collected from electronic medical records, and primary data were collected via telephone interviews. **Results:** The mean age of the patients was 55 years, with females predominating (61.6%). According to the Rankin scale, 92.1% remained asymptomatic, 2.9% had symptoms without disability, 1.2% had moderate disability, 1.7% had severe disability, and 2.1% of patients died. Aneurysm was the most commonly treated condition, accounting for 31.1% of all cases. Other commonly addressed conditions included ischemic stroke, carotid stenosis, vertebral stenosis, and arteriovenous malformation. Cerebral angiography was the most performed procedure (75.2%), followed by cerebral aneurysm embolization, intracranial thrombectomy, and carotid angioplasty. Complications occurred in 7% of procedures, considering death the most common complication, followed by pneumonia, aphasia, and brain death. Primary data collection showed that the majority of patients were asymptomatic or had headaches before the procedure, with frequencies of 41.2% and 38.2%, respectively. In the postoperative period, 75.8% of patients reported no symptoms, 9.1% reported headaches, and a few patients experienced contrast allergy, temporary vision loss, dizziness, paresthesia, and seizures. **Conclusion:** Interventional neuroradiology is a growing field with safe procedures and good outcomes. As evidenced in this study, it is primarily involved in the treatment of aneurysms, ischemic stroke, carotid and vertebral stenosis, and arteriovenous malformations. However, there is a potential for further utilization in other conditions, such as tumor preoperative embolization, a procedure that was underrepresented in the current study. The study demonstrates safety through the low complication rate of procedures and the fact that 92% of patients remained asymptomatic according to the Rankin scale post-procedure. These findings reflect the interventional neuroradiology excellence and underscore the need for its expanded use in nervous system pathologies.

Intestinal microbiome and multiple sclerosis: dysbiosis as a trigger or a reflex of the autoimmune response?

Mariana de Oliveira Trintinalha, André Luiz Fagundes Avila dos Santos[1], Erick Guerra[1], Luciane Filla[2], Débora Marques Herzog[1]

[1]Pontifícia Universidade Católica do Paraná, Hospital Universitário Cajuru, Curitiba PR, Brazil.
[2]Pontifícia Universidade Católica do Paraná, Curitiba PR, Brazil.

Correspondence: Mariana de Oliveira Trintinalha; Email: marianaatrintinalha@hotmail.com.

Background: Multiple sclerosis (MS) stands as a primary demyelinating disease and the second leading cause of disability among young adults in developed nations. This immune-mediated neurodegenerative condition manifests through a myriad of symptoms. Various theories exist concerning the disease's etiology and immune system triggers, with a key focus being the investigation into the dysregulation of the intestinal microbiome. **Objective:** This systematic review aims at unraveling the impact of the intestinal microbiome on the pathogenesis of multiple sclerosis. **Methods:** Employing an integrative literature review approach, this study was conducted between August and December 2023. The search utilized the descriptors "Gastrointestinal Microbiome" and "Multiple Sclerosis." Data were extracted from cohorts, meta-analyses, and cross-sectional studies published in English, Portuguese, or Spanish between 2019 and 2023, sourced from the National Library of Medicine National Institutes of Health (MEDLINE/PUBMED). Exclusion criteria included systematic reviews, content diverging from the microbiome focus, books, protocols, theses, conference publications, and languages not specified. Initial findings yielded 13 articles, with 11 meeting the criteria for analysis. **Results:** The composition of the intestinal microbiome is notably influenced by dietary patterns and disease-modifying therapies, as evidenced by their direct impact on the microbial populations within the gut. Research indicates an association between the development of Multiple Sclerosis and alterations in bacterial populations, such as an increase in Streptococcus and Akkermansia coupled with marked reductions in Faecalibacterium, Bacteroides, Roseburia, and Prevotella. Furthermore, different microbiome patterns were observed based on the different subtypes of Multiple Sclerosis developed by patients. This dysbiosis is linked to individual patient characteristics, including age, antibiotic usage, gender, comorbidities, diet, and probiotic intake. Studies on rodents have demonstrated that fecal transplants can mitigate microglial and astrocytic activation, prevent demyelination, and axonal loss. Additionally, research showcases the immunomodulatory effects of Short Chain Fatty Acids (SCFAs) and tryptophan metabolites originating from the microbiome, facilitating the suppression of autoimmune responses through augmenting T regulatory cell (Tregs) populations. **Conclusion:** Emerging evidence proposes pivotal roles for microbiomes and intestinal immunity in the onset of autoimmune conditions. The comprehension of the functional impact of bacterial populations on the progression of Multiple Sclerosis remains limited. Dietary interventions and disease-modifying therapies might offer benefits in MS management by modulating the microbiome towards an anti-inflammatory composition.

Correspondence: Deborah Araujo Silva; Email: araujodeborah@outlook.com.

Background: Intracranial hemorrhage is characterized by initial bleeding within the brain parenchyma, potentially affecting the meningeal space and subsequently the ventricles. It is one of the most significant traumatic conditions due to its severity and potential for neurological impairment, being a leading cause of morbidity and mortality in Brazil. This event is more common in the elderly population, as this age group is more susceptible to falls due to osteomuscular and neural mechanisms involved in maintaining posture. **Objective:** To evaluate the epidemiological profile of intracranial hemorrhage in Brazil between 2020 and 2022. **Methods:** Data collection was performed using publicly available information from the Hospital Information System of SUS (SIH/SUS) in the Tabnet/DATASUS database between June 1 and August 10, 2023. This retrospective longitudinal study employed a quantitative descriptive approach. Data were grouped by age and educational level for the period from 2020 to 2022. Statistical inference was conducted using BioEstat 5.3 software, utilizing the paired T-test for group comparisons, and data presentation included descriptive statistics, measures of central tendency, and dispersion. **Results:** Between 2020 and 2022, there were 91,821 cases of intracranial hemorrhage in Brazil. The highest number of cases was concentrated in the Southeast region (n=13,573), accounting for 44.34% of the total, with annual treatment costs averaging approximately R$ 64,356,563.46. The Southeast region also had the highest number of deaths, accounting for 47.74% (n=10,410) of the total, with a mortality rate of 25.57. The number of hospitalizations varied over the years, with 33,093 cases (36.04%) occurring in 2022 compared to 30.99% (n=28,459) in 2020. Regarding the classification of care, 94.19% (n=86,486) of cases were urgent, while 5.81% (n=5,335) were elective. In terms of sex, 51.81% (n=47,576) of the cases were male and 48.19% (n=44,245) female (test t p=0.0679). Elderly individuals aged 60 to 69 were most affected, accounting for 22.12% (n=20,313) of cases, followed by those aged 50 to 59 at 21.83% (n=20,040). Regarding race/ethnicity, 39.84% of the cases were self-declared as mixed race (n=36,586) and 32.88% as white (test t p=0.1191). **Conclusion:** Intracranial hemorrhage cases are predominantly concentrated in the Southeast region of Brazil, which accounts for the highest proportion of deaths and treatment costs, associated with the highest mortality rate among regions. The majority of cases occur among men aged 50 to 69 years, who are self-declared as white or mixed race, with urgent care being the most prevalent type of hospitalization.

Intracranial hypotension secondary to dural fistula and complicated in cerebral venous thrombosis (CVT)

Victor Cardoso de Faria[1], Andre Felipe Candêas Amorim[1], Gabriel Pinheiro Martins de Almeida e Souza[1], João Victor Cabral Correia Férrer[1], Márcio Pinheiro Lima[1], Ruan Gambardella Rosalina de Azevedo[1], Adriel Rêgo Barbosa[1], Rafael Tuzino Leite Neves Maffei[1], Lucas de Oliveira Cantaruti Guida[1], Enedina Maria Lobato de Oliveira[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Victor Cardoso de Faria; Email: victor_cardoso13@hotmail.com.

Case presentation: A 53-year-old woman, previously diabetic and with degenerative spine disease, started a new, frontal, oppressive, mild headache 5 months before admission, which partially improved with analgesics, without nausea, vomiting, photophobia or phonophobia. There was no worsening of pain with decubitus or orthostasis, as with Valsalva. Two days before admission, she developed a headache that progressed to very severe intensity within a few minutes, left sided, radiating to the occiput, associated with nausea and vomiting, which worsened markedly when assuming an upright position and improved in supine. She denied auditory or visual symptoms. On neurological examination, she showed no changes, fundus with well-defined papillae. A head CT was performed with a venous study, showing CVT of the transverse sinuses and confluence of the sinuses, as well as a small frontal subdural hematoma. Investigation progressed for intracranial hypotension, brain MRI showed diffuse pachymeningeal enhancement associated with brain sagging. Lumbar puncture was performed with opening pressure of 6 mmHg, cellularity 3, 10 red blood cells. Myelotomography revealed extrathecal contrast next to the interspinous foramina at multiple cervical and thoracic levels, which may correspond to perineural diverticula/cysts associated with CSF leakage. The diagnosis of spontaneous intracranial hypotension secondary to multiple spinal CSF leaks was confirmed. The patient underwent conservative treatment associated with full anticoagulation, given the difficulty in approaching the multiple lesions with a blood patch and/or surgery. He was discharged with complete clinical improvement. **Discussion:** Spontaneous intracranial hypotension requires for its diagnosis the presence of CSF pressure lower than 6 cm H2O and/or evidence of CSF leak on imaging examination, according to ICHD-3. Patients may present with atypical initial presentations, such as cochleovestibular manifestations, cranial nerve

palsy, personality changes, or even movement disorders. Cases may present with thunderclap headache, patients who developed complications such as subdural hematoma or cerebral venous thrombosis may present a change in the headache pattern, with loss of the typical postural component. Trauma, hypermobility and osteoarthritis of the spine are risk factors. Myelotomography is considered the gold standard in locating spinal CSF leaks. Treatment options are a conservative approach, blood patch (early or if conservative treatment fails) or surgery (refractory cases). **Final comments:** Intracranial hypotension is an important secondary cause of headache, associated with relevant morbidity and mortality and a specific therapeutic approach. This is an underdiagnosed disease and should also be a differential diagnosis for patients with headaches that are daily from onset, refractory to everything and chronic headaches that do not fit into a specific phenotype.

https://doi.org/10.5327/CBN240974

Intraoperative electrocorticography (ECOG) tailored resection in nonlesional epilepsy and focal cortical dysplasia

Fernanda Schuh Martins[1], William Alves Martins[1], Rafael Paglioli[1], Thomas Frigeri[1], Eliseu Paglioli[1], André Luis Fernandes Palmini[1], Ricardo Paganin[1]

[1]Universidade Católica do Rio Grande do Sul, Hospital São Lucas da Pontifícia, Porto Alegre RS, Brazil.

Correspondence: Fernanda Schuh Martins; Email: fschuhmartins@gmail.com.

Background: Electrocorticography (ECoG) has long been used to guide the resection of epileptic tissue. Acute ECoG offers advantages such as cost-effectiveness, the ability to tailor resections, and the assessment of residual epileptic foci. While ECoG is proven to provide crucial information for tailoring resections in focal cortical dysplasias (FCD), its role in nonlesional patients is less well established. **Objective:** This study investigates the usefulness of ECoG in patients undergoing epilepsy surgery with either nonlesional or FCD-positive MRI. **Methods:** Ninety-four patients from the Porto Alegre Epilepsy Surgery Program (PAESP) were included. All underwent ECoG-tailored surgery from 2012-2019 and had at least 12 months of follow-up. Intraoperative ECoG recordings were performed using long-range, carbon or gold-plated ball-pointed 16-electrode sets, allowing for acute probing of electrical activity from the surface, lateral banks, and depths of gyri. Recordings lasted between 15 and 30 minutes and were performed sequentially at each resection stage. Electrode positioning was customized at each stage under direct visualization of the cortical regions being explored. **Results:** Electrocorticographic epileptiform findings were classified as: 1) continuous/quasi-continuous spikes - rhythmic and frequent bursts of spikes recurring at 0.5-2Hz; 2) recurrent rhythmic polyspikes or burst-suppression - bursts of at least 3 spikes or fast activity followed by attenuation; 3) recruiting ictal rhythm (EEG seizure); 4) frequent non-rhythmic spikes - more than 10 epileptiform spikes/sharp waves per minute; 5) sporadic spikes - fewer than 10 epileptiform spikes/sharp waves per minute. ECoG patterns 1-3 were considered dysplastic and were more commonly found in extratemporal epilepsies (81% vs. 59%, p=0.024). Complete resection of the most active ECoG region significantly improved outcomes, with an OR of 9.5 (CI 95% 2.4-37) for becoming seizure-free (61% vs. 14%, p=0.001). FCD II was found in 21/26 patients (81%) with continuous/quasi-continuous patterns (ECoG 1) and in 7/15 (47%) with recurrent rhythmic polyspikes (ECoG 2), whereas FCD I was seen in 4/11 patients (30%) with frequent non-rhythmic patterns (ECoG 4) and in 5/21 (24%) of those with sporadic spikes (ECoG 5) [p=0.017]. In non-lesional patients, ECoG most often showed sporadic spikes (14 [35%]) and frequent non-rhythmic spikes (11 [27%]), whereas those with lesional MRI had higher rates of continuous/quasi-continuous spikes (23 [40%]) and bursts of polyspikes/burst-suppression (10 [18.2%]; p=0.023).**Conclusion:** ECoG added significant value in tailoring resections in both lesional and nonlesional cases. This surgical strategy provided a reasonable chance of resecting the epileptogenic zone even in patients with nonlesional MRI. However, the pattern of sporadic spikes is common in nonlesional patients, appearing in 35% of intraoperative ECoG recordings, which can complicate the delimitation of the epileptogenic zone.

https://doi.org/10.5327/CBN240975

Intrathecal pemetrexed for leptomeningeal carcinomatosis in EGFR-mutated NSCLC with severe renal impairment

Thales Pardini Fagundes[1], Amélia Gontijo Velozo de Melo[1], Ingrid Marriel Ramos Novais[1], Victoria Almeida Freire[1], Roberta Martins Queiroz Barbosa[1], Beatriz Olmo Salles[1], Gustavo Dix Junqueira Pinto[1], Carlos Eduardo Baston Silva[1], Flavio Augusto Ferreira da Silva[1]

[1]Fundação Pio XII, Hospital de Câncer de Barretos, Barretos SP, Brazil.

Correspondence: Thales Pardini Fagundes; Email: pardinithales@gmail.com.

Case presentation: A 68-year-old woman with EGFR exon 19-deleted non-small cell lung cancer (NSCLC) developed leptomeningeal disease (LD) after seven years of treatment, including gefitinib and osimertinib. With severe renal dysfunction (creatinine clearance 18 ml/min/m^2), we administered intrathecal (IT) pemetrexed 50 mg on days 1 and 21, with IT dexamethasone, alongside daily osimertinib 80 mg. Treatment was well-tolerated without increased toxicity. Cerebrospinal fluid analysis (CSF) showed an increase in malignant cells from 30% to 36%, and brain MRI revealed communicating hydrocephalus. The regimen continued every 28 days, with close monitoring of safety and efficacy. **Discussion:** This case represents the first reported use of IT pemetrexed in an NSCLC patient with severe renal impairment. LD in EGFR-mutated NSCLC poses significant treatment challenges, even with osimertinib's CNS efficacy. Previous studies have shown IT pemetrexed's efficacy in LD, with doses of 10-50 mg weekly demonstrating response rates of 43.5-80.3%. However, data on renal dysfunction is lacking. Our experience suggests that IT pemetrexed can be safely administered to patients with severe renal impairment without increased toxicity. This finding is crucial, as pemetrexed is predominantly renally cleared, with intravenous administration contraindicated for creatinine clearance under 30 ml/min. The absence of established dose adjustments for IT administration in renal impairment underscores the significance of our case. Despite combining IT pemetrexed with osimertinib, clinical benefit was modest in our heavily pretreated patient. This outcome highlights the need for earlier intervention, novel combinatorial approaches, and individual dosing based on CSF flow dynamics to improve outcomes in LD. Comments: This case expands the limited data on IT pemetrexed in LD with severe renal dysfunction. While our patient tolerated the treatment well, efficacy was limited, possibly due to late-stage disease. Prospective trials are needed to establish the safety, efficacy, and optimal dosing of IT pemetrexed in this challenging population. Our experience opens new avenues for managing LD in EGFR-mutated NSCLC patients with renal impairment, a group often excluded from standard treatments. It underscores the potential of IT chemotherapy in overcoming systemic limitations and targeting the CNS directly. **Final comments:** Future research should focus on earlier intervention, novel drug combinations, and personalized approaches to improve outcomes in this aggressive disease manifestation. This case serves as an important step forward, demonstrating that innovative approaches can expand treatment options for patients with limited choices. It emphasizes the importance of individualized medicine and the need for continuous exploration of new strategies in managing complex cancer presentations.

Background: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disorder characterized by the progressive degeneration of motor neurons, leading to debilitating muscle weakness, atrophy, and paralysis. Excitotoxicity plays a pivotal role in the neuronal death and dysfunction observed in ALS. Human dental pulp stem cells (hDPSCs) exhibit anti-inflammatory, anti-apoptotic, and neurotrophic properties, suggesting potential therapeutic benefits for ALS. **Objective:** To investigate the therapeutic potential of intravenous delivery of hDPSCs in a murine model of ALS (SOD1G93A mice). **Methods:** This was a case-control study with animals split into 3 experimental groups (hDPSC, n=7; vehicle, n=5; non-transgenic, n=5). To track the distribution of transplanted cells throughout the spinal cord, hDPSCs were labeled with Qtracker 655 (Thermo Fisher) and observed twenty-four hours after transplantation. The treatment was carried out in the asymptomatic phase of the disease (10th week) by a single systemic application of hDPSCs (1x106 cells/kg). The animals were euthanized (n=5) at the 15th week (initial stage of symptoms) of the disease and the lumbar spinal cords were dissected and processed for Nissl staining (neuronal survival) and immunofluorescence (astrocytosis and microglial reactions). Behavioral analyses considering the onset of disease and its progression, neurological score, body weight, and motor control (rotarod test) started on the 10th week and were performed every week until dissection. **Results:** Transplanted hDPSCs were detected throughout the lumbar spinal cord 24 hours after intravenous injection, primarily within the gray matter's Rexed lamina IX, indicating successful target delivery. This treatment resulted in significantly greater neuronal survival (83% vs 27%, p<0.05) compared to the vehicle-treated group, demonstrating a neuroprotective effect. In addition to promoting neuronal survival, the cell therapy also demonstrated a beneficial effect on glial responses. Astrogliosis and microglial reactivity were significantly reduced in the treated group (p<0.05). These findings are aligned with the observed behavioral data, where hDPSC-treated animals had delayed motor deficits and onset the disease, and reduced weight loss compared to the vehicle group. **Conclusion:** Overall, our data demonstrate the therapeutic potential of hDPSCs in a murine model of ALS. Intravenous delivery enhanced neuronal survival, reduced gliosis, and improved structural preservation of the ventral horn. These effects were associated with delayed disease progression, as evidenced by attenuated

motor deficits, reduced weight loss, and a later onset of disease symptoms in treated animals. Thus, our preclinical findings provide evidence that this stem cell lineage may be a promising therapeutic strategy for ALS.

Intravenous thrombolysis in a patient with embolism in the left middle cerebral artery following recent postoperative osteosynthesis of the distal radius and thoracic spine arthrodesis after severe spinal cord trauma

Maria Júlia Branco Rodrigues[1], Paulo Victor Machado[1], Marcos Seefeld[1], Frederico Otto Flores Moraes[2], João Pedro Gorski Ribas de Araujo[2], João Pedro Greca de Macedo Biasi[2], Guilherme Costa Barghouthi[2], Ana Paula Gonçalves Barankiewicz[1], Lucas Rodrigues Prim[1], Lisseth Fabiola Vallejo Reyes[1]

[1]Hospital Universitário Evangélico Mackzenie, Curitiba PR, Brazil.
[2]Faculdade Evangélica Mackenzie do Paraná, Curitiba PR, Brazil.

Correspondence: Paulo Victor Santos Machado; Email: paulovictorsmachado@gmail.com.

Case presentation: A 32-year-old male patient, without comorbidities, suffered polytrauma from a motorcycle-car collision, resulting in a spinal cord injury (SCI), classified as Frenkel A. He underwent osteosynthesis of the right distal radius and thoracic spine arthrodesis. Despite surgical correction, he maintained paraplegia with a sensory level at T9. On the 10th postoperative day, he experienced an acute focal deficit, witnessed by the medical team, and was transferred to a referral hospital. Upon admission, the patient presented with motor aphasia, in addition to deficits secondary to severe SCI, with an admission NIHSS score of 2 (aphasia). Cranial and cervical computed tomography angiography showed cortical and subcortical hypodensity in the left temporal region, suggestive of an ischemic stroke (IS) in the left middle cerebral artery (MCA), with an ASPECTS score of 10. Despite absolute contraindications to chemical thrombolysis, such as two recent surgeries (<14 days), the patient underwent the procedure. After thrombolysis, the patient showed complete resolution of aphasia, with no bleeding at any point. Two days after the IS, the patient developed deep vein thrombosis (DVT) in the right lower limb, and anticoagulation with enoxaparin was initiated. One day after this diagnosis, he developed fever spikes and tachycardia, and was diagnosed with bilateral pulmonary embolism (PE), confirmed by imaging, despite full anticoagulation. An etiological investigation of the recurrent ischemic events was conducted, including a transesophageal echocardiogram with bubble test, which revealed a patent foramen ovale (PFO) with significant flow. Additionally, thrombophilias were investigated and ruled out. To determine the etiology of the IS, ROPE and PASCAL scores were used, both scoring 9 points, suggesting a high probability that the ischemic events were secondary to the PFO. After 21 days, the patient was discharged with rivaroxaban. **Discussion:** This case involves a severely polytraumatized patient with no known risk factors for thrombotic events, prompting clinical reasoning to find the etiology of the embolic occurrences. Despite being contraindicated, thrombolysis completely reversed the deficit without hemorrhagic complications, opening a discussion about the recurrence rate of embolic events post-thrombolysis in patients with absolute contraindications for such a procedure. **Final comments:** This case highlights the complexity of managing a polytraumatized patient and its developments in a patient with a previously undiagnosed PFO, who experienced multiple embolic events. The identification of the neurological deficit and the decision for immediate thrombolysis, with the consent of the patient and family, successfully reversed the deficit. These facts underscore the necessity of following a clinical reasoning process to reach a diagnosis. The favorable recovery demonstrates the efficacy of an integrated and thoughtful approach.

[3]Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Érica Paiva Espinosa; Email: erica.espinosa@sou.ucpel.edu.br.

Case presentation: Aggressive infections such as invasive fungal rhinosinusitis have been most frequently associated with immunocompromised patients, as those with hematologic malignancies, advanced HIV disease, or diabetes mellitus. Upper respiratory tract infections (URTIs) are mostly caused by viruses and bacteria, rarely evoked by funguses. The most prevalent fungal agents responsible for colonizing the upper respiratory tract are Aspergillus, Fusarium, and Mucorales. Clinical manifestations of invasive fungal rhinosinusitis include acute fever, facial pain, nasal congestion, visual alterations, and mental confusion. This report aims to present a rare case report of a young male patient presenting invasive fungal rhinosinusitis caused by Rhizopus oryzae, with important central nervous system (CNS) impairment and surgical outcome. **Discussion:** A 10 year-old-male, from Rio Pardo-RS, developed polyuria, abdominal pain, progressive asthenia, and headache in March 2024, leading to a diagnosis of diabetic ketoacidosis and diabetes mellitus type 1. Additionally, the patient showed signs of nasal congestion, which led us to the sinusitis diagnosis. He developed fungal meningitis, aggressive behavior and agitation, in addition to eyelid edema and visual acuity loss. He was therefore referred to neurosurgical intervention due to suspicion of cerebral edema and optic neuritis. Magnetic Resonance Imaging (MRI) and Computed Tomography (CT) scans indicated signs consistent with fungal infection that had spread to the nasal cavities and CNS. Furthermore, the complication identified included fusiform pseudoaneurysm of the anterior cerebral artery and acute ischemic events. The diagnosis of invasive fungal rhinosinusitis was confirmed after debridement and positive culture for Rhizopus oryzae complex. After craniotomy for brain abscess, the patient still showed signs of complications on imaging tests, such as liquid and gas collections, signs of vasculitis and reduced caliber of the left internal carotid artery. **Final comments:** In this case report, we describe a rare manifestation of invasive fungal rhinosinusitis caused by Rhizopus oryzae involving the central nervous system (CNS) of an immunocompromised patient with type 1 diabetes mellitus. This patient exhibited extensive clinical manifestations of fungal infection, including ocular lesions, cerebral vasculature invasion, and bifrontal granulomatous fungal abscesses. All efforts were made to protect the patient's privacy and confidentiality.

Correspondence: Amanda Morato do Canto; Email: amcanto@unicamp.br.

Background: Mesial temporal lobe epilepsy (MTLE) is the most prevalent form of focal epilepsy in adults, posing significant clinical hurdles due to a high resistance rate to standard antiseizure medications. Delving into the intricacies of synaptic transmission, particularly its processes and potential abnormalities, is pivotal for comprehending the mechanisms underpinning MTLE. Synaptosomes, housing essential machinery for neurotransmitter release, reuptake, and storage, offer a unique window into synaptic function. **Objective:** This study explores the proteomic and metabolomic profiles of synaptosomes isolated from the anterior temporal lobe and hippocampus of patients with pharmacoresistant MTLE and hippocampal sclerosis. **Methods:** In this study, we employed a unique approach to investigate synaptosome proteomic and metabolomic profiles. These synaptosomes were isolated from hippocampal and anterior temporal lobe tissue obtained during epilepsy surgery, including samples from pharmacoresistant MTLE patients (N=20) and post-mortem controls (N=5). Our data acquisition was performed using cutting-edge technologies, including an Orbitrap EclipseTM TribridTM mass spectrometer for proteomic data and an LCMS-9030 quadrupole time-of-flight (Q-TOF) Shimadzu instrument for metabolomic data. The subsequent bioinformatics analysis, conducted using ProteomeDiscoverer and R software, was complemented by SynGO, STRING PPI, and ClueGO analyses to investigate biological alterations. **Results:** Our study revealed significant variations in protein and metabolite compositions among synaptosomes from different brain structures, underscoring the complexity of MTLE pathology. Notably, patient synaptosomes showed a preponderance of presynaptic proteins, with observed alterations in neurotransmitter release cycles and receptor dynamics. These findings, along with evidence of increased sensitivity to toxic substances, suggest potential implications for drug metabolism within the hippocampus of patients with pharmacoresistant MTLE. **Conclusion:** Our study has delineated distinct protein and metabolite profiles within synaptosomes from various brain structures in patients with pharmacoresistant MTLE. The predominance of presynaptic proteins and observed alterations in neurotransmitter release cycles and receptor dynamics highlight the complex molecular underpinnings of MTLE pathology. These findings advance our understanding of MTLE pathogenesis and provide valuable insights into potential therapeutic targets and avenues for further investigation. By shedding light on the molecular landscape associated with pharmacoresistant MTLE, our results may improve management strategies for these patients, potentially leading to the development of novel therapeutic approaches.

Irreversible bilateral ischemic optic neuropathy in the post-operative myocardial revascularization setting: case report

Pâmela Ritzmann de Lima[1], Laís Cristina Marques Moura[1], Brenda Jahn Henning[1], Patrícia de Morais Della Justina[1], Sabrina Cristof[1], Oscar Nelson Reimann[2], Michael Ricardo Lang[2], Felipe Negrão[2], Chelin Auswaldt Steclan[3], Diogo Pasquali Nones[2]

[1]Universidade do Contestado, Mafra SC, Brazil.
[2]Hospital São Vicente de Paulo e Grupo Neuromax, Mafra SC, Brazil.

[3]Universidade Federal de Santa Catarina, Florianópolis SC, Brazil.

Correspondence: Pâmela Ritzmann de Lima; Email: pamelaritzmann@gmail.com.

Case presentation: Male, 71 years old, white, hypertensive, overweight, with severe coronary insufficiency, heart failure (HF), sleep apnea, dyslipidemia, post-myocardial revascularization surgery (without complications) with extracorporeal circulation (ecc). In the immediate postoperative period (PO), he was sent to the intensive care unit (ICU) due to spikes in arterial hypotension, desaturation (requiring norepinephrine) and anemia. On the 4th PO, in the ward, he developed decreased visual acuity and subsequent loss of complete vision (5th PO), without reaction to light. brain tomography ruled out a stroke, while magnetic resonance imaging (MRI) revealed hypoglycemic encephalopathy, cause of cortical blindness due to amaurosis; by retinography, peridiscal micro-hemorrhages were evident, with a bilateral atrophic area. He was discharged on the 10th PO, with the diagnostic hypothesis of hypoglycemic encephalopathy. However, without showing any improvement in the condition, on the 11th day after vision loss, an eye fundus examination and fluorescein angiography revealed: edema, pallor of the papilla, signs of hypo fluorescence and candle flame hemorrhage, considering hypothesis of anterior ischemic optic neuropathy (AION). On the 17th day after amaurosis, skull MRI showed nonspecific changes in optic nerves, corroborating NAION. Inflammatory tests were conducted, with results within normal limits. Pulses with methylprednisolone (3x/day) were then performed, however, without improvement. On the 50th day after visual loss, a new fundus examination revealed: pallor and reduction in papillary edema; optic nerve atrophy; confirming bilateral non-arteritic AION (NAION). After one year of PO, the patient developed a diagnosis of total blindness, remaining in bilateral amaurosis and without perception of light. **Discussion:** Perioperative visual loss is a rare and feared complication in the postoperative period of non-ophthalmic surgeries, which can result in serious and irreversible damage. The patient, here in the PO of cardiac surgery, had preoperative risk factors (comorbidities), which in addition to postoperative risk factors (hemodynamic decompensation and use of vasoactive drugs) contributed to NAION. This condition is related to optic nerve infarction, resulting in hypoperfusion and ischemia. It has been shown that NAION is a diagnosis of exclusion, which makes its diagnosis difficult. Treatments do not have good evidence of effectiveness so far, so the prognosis tends to be darker, considering the prevention of risk factors essential. **Final comments:** Recognizing the previous clinical history, immediate anatomical and etiological diagnosis is essential to guide the diagnosis, management, and prognosis of NAION. Case reports like this tend to contribute to the recognition of rare complications, decentralizing health information, as well as its applicability.

Irreversible paraplegia following benzathine penicillin injection: a case report

Monique Melo Fortaleza[1], Felipe Melo Leal[2], Victor José Campelo Vilanova[1], Janine Midori Figueiredo Watanabe[1], Fabbricio Santos Castelo Branco[3], Tibério Silva Borges dos Santos[3], Cristina Reis de Sousa Brito Rocha[2], Jonh Heberthon de Souza Araújo[1]

[1]Universidade Estadual do Piauí, Teresina PI, Brazil.
[2]Universidade Federal do Piauí, Teresina PI, Brazil.
[3]Hospital Getúlio Vargas, Teresina PI, Brazil.

Correspondence: Monique Melo Fortaleza; Email:

Case presentation: A 30-year-old male with no comorbidities or prior allergies presented to a local hospital with fever and odynophagia, where he received a dose of benzathine penicillin in the left gluteal region. Eight minutes later, he developed paralysis and cyanosis of the lower limbs, abdominal pain, melena, and hematuria. He was promptly admitted to intensive care, exhibiting signs of tissue injury at the injection site, paresthesia, non-fixed cyanosis, and livedo on the lower limb extremities, with amputation under consideration. His condition deteriorated presenting anuria and decline in overall condition. Two weeks later, he was transferred to a referral hospital where hemodialysis was initiated, leading to the restoration of diuresis, and had no further episodes of melena. In the ward, ten days later, he continued to experience paraplegia and developed ecchymotic patches on the trunk, with improvement in paresthesia and cyanosis. In light of the suspicion of transverse myelitis, he underwent thoracolumbar spine MRI, confirming hypersignal in T11-L1, electroneuromyography showing severe plexopathy, in addition to laboratory evaluation, serological tests, venous Doppler ultrasound, and lumbar puncture, ruling out other etiologies. Given the symptoms and their temporal association with a medication injection, the diagnosis of Nicolau syndrome was established. The patient was discharged with a catheter, experiencing dual sphincter incontinence and no motor improvement, for physiotherapy follow-up. **Discussion:** Transverse myelitis is characterized by acute or subacute spinal cord injury causing motor, sensory, and autonomic alterations. It is estimated to affect approximately 1 to 4 new cases per million individuals annually, with no clear genetic or gender predisposition. Etiologically, it can be autoimmune, infectious, drug-induced, and rarely associated with medication injection, particularly non-steroidal anti-inflammatory drugs or benzathine penicillin, precipitating the complication known as Nicolau syndrome. This clinical entity involves skin, subcutaneous, and muscular tissue reactions, attributed to medication embolism or arterial vasospasm due to intra-arterial injection. Diagnosis is clinical and exclusionary, and although it is more common in women and obese individuals, the symptoms align with the patient's clinical picture, including: livedoid vasculopathy, a pathognomonic sign; renal failure from rhabdomyolysis; gastrointestinal bleeding; hypoesthesia and paraplegia caused by plexopathy and myelopathy. There is no established standard treatment for the syndrome, largely due to its low incidence. **Final comments:** Although Nicolau syndrome is rare, it is extremely harmful, emphasizing the need for healthcare professionals to exercise vigilance in its prevention. This includes selecting injection sites in the gluteal region that have smaller-caliber vessels, given the frequent administration of medications in this area.

Is artificial intelligence ready to teach epilepsy through images?

Felipe Guimarães Kanda[1], Luma Hussein Salem[1], Raquel Guimarães Kanda[2], Rafael Guimarães Kanda[3], Paulo Afonso Medeiros Kanda[4]

[1]Universidade de Taubaté, Taubaté SP, Brazil.
[2]Universidade Federal do Cariri, Barbalha CE, Brazil.
[3]Universidade Estadual de Campinas, Campinas SP, Brazil.
[4]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Felipe Guimarães Kanda; Email: felipekanda99@gmail.com.

Background: Artificial intelligence (AI) has shown significant potential in various areas of medicine, including neurology. With the increasing availability of data and advances in machine learning algorithms, the question arises: is AI ready to contribute to the teaching and understanding of epilepsy? Epilepsy is a complex neurological condition characterized by recurrent episodes of seizures, the understanding of which is essential for healthcare professionals, patients, and their families. This study investigates the feasibility of using AI to generate illustrative images of epileptic seizures from descriptions provided in command prompts. **Objective:** To explore the ability of artificial intelligence, specifically language models like GPT-3.5, in conjunction with AI-assisted design tools to generate illustrative images of epileptic seizures from textual descriptions and base images. We aim to assess the quality and usefulness of these generated images in facilitating the understanding of epilepsy by healthcare professionals, patients, and families. **Methods:** We used the GPT-3.5 language model to generate command prompts based on descriptions of different types of epileptic seizures, including physical, behavioral, and temporal characteristics. Image Generation: We tested AI image generators (Copilot, Getimg.ai, bing.com, shakker, aigenerator) apps to translate the command prompts into illustrative images of epileptic seizures. **Results:** The generated images were evaluated by a neurophysiologist, PhD MD titular member of the Sociedade Brasileira de Neurofisiologia Clínica (SBNC) to determine images accuracy, clarity, and utility in an educational context. Results Preliminary results indicate that the combination of GPT-3.5 and AI image generators were able to generate illustrative images of epileptic seizures visually informative and similar to reality. Nevertheless, some images were bizarre, inaccurate and deceptive. Besides, in all cases, the research team modified and adjusted GPT-3.5 prompt, while testing image generation, until images were minimally useful. **Conclusion:** This study demonstrates the potential of artificial intelligence to assist in the teaching and understanding of epilepsy. The generation of illustrative images from textual descriptions offers an innovative and accessible approach to the study of epilepsy. However, further research is needed to validate the accuracy and effectiveness of these images in clinical and educational contexts. The ongoing advancement of AI promises to further improve our ability to teach and manage complex neurological conditions such as epilepsy.

Is Lhermitte's sign in the first acute episode associated with earlier diagnosis of multiple sclerosis?

Felipe Asaf Borges Millard[1], Thaís Barbosa de Oliveira[1], Antonio Lázaro Santos Soares Junior[1], Julia Xavier Oliveira[1], Vinícius Bessa Mendez[1], Gabriel Souza Suzart[1], Pedro Antonio Pereira de Jesus[1,2], Bruno Bacellar Pedreira[2], Thiago Gonçalves Fukuda[2]

[1]Universidade Federal da Bahia, Salvador BA, Brazil
[2]Hospital Universitário Professor Edgard Santos, Salvador BA, Brazil.

Correspondence: Felipe Asaf Borges Millard; Email: felipemillard@ufba.br.

Background: Multiple sclerosis (MS) is among the most common causes of neurological disability in young adults worldwide. Among its variety of symptoms, Lhermitte sign (LS) is a sudden electric shock sensation in the cervical region, usually when flexing the neck. Despite being described in other myelopathies, LS is more commonly described in MS, a fact that raises questions about its clinical and diagnostic significance for MS. The influence of LS in time-to-diagnosis of MS is unknown. **Objective:** To evaluate the association between the manifestation of LS in the first acute episode of the disease and the time between the first visit to the doctor and the definitive diagnosis of MS. **Methods:** Cross-sectional study with patients diagnosed with MS (according to the McDonald 2017 criteria), who were followed up at a neuroimmunology reference center in Bahia, from January 2019 to June 2024. The presence of LS in the first acute episode and the period between the search for the first doctor until the definitive diagnosis of MS were reported by clinical interview. The inclusion criteria were patients with definitive diagnosis of MS and without report of flare-up in the last three months until admission. The Mann-Whitney test was used to compare the period from the first medical consultation to the definitive diagnosis between individuals with LS+

and LS-. **Results:** A total of 203 patients were included in the study, of whom 141 (69.5%) were female, the mean age of the sample was 41.6 years (SD±14) and the most frequent ethnicity was brown (47.3%), followed by white (26.1%) and black (25.1%). The most frequent level of education was complete higher education (33.3%), followed by complete secondary education (30.5%) and incomplete higher education (14.3%). The most commonly described clinical form of MS was relapsing-remitting, with 176 individuals (86.5%). LS was present in 60 (29.6%) patients in their first acute illness. The median time between seeking the first doctor and the definitive diagnosis of MS was not different between LS+ and LS- groups [7 (2-25) vs 4 (0-20) months; p=0.078]. **Conclusion:** The diagnosis of MS and its timing is an important challenge for this population. Although a considerable number of patients presented with LS in the first acute episode, it was not associated with an earlier diagnosis or a shorter time to diagnose MS.

Is there a relationship between atopic dermatitis and stroke? A systematic review and meta-analysis is there a relationship between atopic dermatitis and stroke?

Luiz Carlos Figueiredo Filho[1], Walter Oliveira Verissimo[2], Maria Fernanda de Almeida Cavalcante Aranha[1], Ricardo Ormanes Massoud[1], Isadora Rocha Rosa[1], Lucas Silva Cabeça[2], Rafael Augusto Silva Cabeça[1], Ingrid Jade Muniz Wanderley[1], Alexandre Marques da Rocha[1], Andrew Moraes Monteiro[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil. [2]Universidade Federal do Pará, Belém PA, Brazil.

Correspondence: Walter Oliveira Verissimo; Email: walterverissimo17@gmail.com.

Background: Atopic dermatitis (AD) has a chronic inflammatory character and intense pruritus that affects the skin tissue, afflicting 13% of children and 7% of adults. Recently, atopic dermatitis has been associated with other immunological and cardiovascular morbidities, with stroke being one of the most prevalent globally, with a 25% risk of occurrence after the age of 25, making it the second leading cause of mortality. **Objective:** To analyze the association between atopic dermatitis and stroke. **Methods:** This is a systematic review and meta-analysis of observational studies focused on the prevalence of stroke and atopic dermatitis in the same population. Articles were selected from the PubMed, VHL, Embase, Cochrane Database, Web of Science and Clinical Trial.gov databases. The PRISMA flowchart was used for data collection, with Covidence software for screening and selection. The risk of bias analysis was conducted using the ROBINS-I tool. Data meta-analysis was carried out using Review Manager 5.4 software. For continuous variables, the inverse variance method was used to group mean differences (MDs) with 95% confidence intervals (CIs). Heterogeneity was assessed using the chi-squared test. **Results:** Of the 365 articles found, 12 were included for qualitative and quantitative analysis. The primary endpoint of stroke was performed globally followed by a subgroup analysis according to the type of stroke. This outcome had a higher risk for ischemic stroke (HR = 1.19, 95%CI 1.13 - 1.26) compared to the risk of hemorrhagic stroke (HR = 1.13, 95%CI 1 - 1.29), with no statistical significance in the increased risk in patients with AD with hemorrhagic stroke. Furthermore, for the second analysis, patients with moderate AD had a lower risk of stroke (OR = 1.06, 95%CI 0.88 - 1.27) compared to severe AD (OR = 1.06, 95%CI 0.88 - 1.27). For the Risk Ratio analysis, only one study had data that were used for grouping, showing a correlation in the overall risk of stroke (RR = 1.04, 95%CI 1 - 1.07). The funnel plot showed significant heterogeneity in the HR results, which was lower in the OR results. **Conclusion:** In summary, there is a relationship between Atopic Dermatitis and Ischemic Stroke. However, there is a need for studies in different populations, to better describe the disease and other risk factors for stroke associated with the participants. Limitations of the study include the limited number of studies for analysis, risk of bias and heterogeneity. Thus, more studies on the subject are needed, including the relationship between AD treatment and stroke risk reduction, as well as the prevalence of other associated factors.

Ischemic myelopathy, a rare vascular syndrome: case report and literature review

Monique Evelyn Mendonça do Nascimento[1], Marcelo Ataíde de Lima[1], Mariana Holanda Gameleira[1], Ricardo Martins Silva[1], Maria Eduarda Moreira Cardoso[1], Gregory Ramon Bandeira da Silva[1], Rosevaldo Alves Junior[1], Stefan Welkovic Junior[1], Ana Dolores Firmino Santos do Nascimento[1], Noelle Ventura Jordão[1]

[1]Hospital da Restauração, Recife PE, Brazil.

Correspondence: Monique Evelyn Mendonça do Nascimento; Email: moniqueemnascimento@gmail.com.

Case presentation: A 64-year-old female patient with cardiovascular comorbidities (hypertension and dyslipidemia) presented with sudden low back pain followed by weakness and reduced sensation in her lower limbs. A neurosurgeon ruled out any compressive injury or surgical pathology. A CSF analysis was normal. Treatment with methylprednisolone pulse therapy for 5 days did not improve her symptoms. Tests for schistosomiasis were negative. MRI of the thoracic and lumbar spine showed hyperintensity in the dorsal medulla and the medullary cone, indicating anterior involvement of the medulla, leading to a diagnosis of ischemic myelopathy. There was a slight tumefactive effect in the medullary cone, but no significant enhancement after venous contrast. The MRI also revealed extensive atheromatosis in the aorta. Overall, the findings suggest that the patient has ischemic myelopathy, potentially caused by atherosclerosis in the aorta. **Discussion:** The spinal cord, especially the thoracic portion, is particularly dependent on radicular vascular contributions and may be the most vulnerable to infarction. The most prominent thoracic radicular artery is the artery of Adamkiewicz. Spinal cord ischaemia is a rare occurrence caused by the occlusion of part of the complex vascularization network of the spinal cord. Ischaemic myelopathy accounts for less than 1.0% of all strokes. It has a higher prevalence in elderly patients and those with comorbidities: atherosclerosis, hypertension and diabetes mellitus. The ischaemic myelopathy is associated with diffuse atheromatous disease of the aorta. Also, most cases are caused by aortic disease and repair (after an aortic surgery). MRI plays a crucial role in the diagnostic investigation and can help differentiate it from other myopathies. T2-weighted and diffusion-weighted MRI have proved to be the most useful diagnostic tools for establishing a definitive diagnosis. The clinical course after spinal cord infarction is variable. **Final comments:** Ischaemic myelopathy is a rare neurological emergency that lacks specific management guidelines. We highlight the importance of rehabilitation, reducing vascular risk factors and maintaining a healthy lifestyle. Despite severe deficits, approximately 50% of patients end up walking unaided. The patient returned to the neurology clinic after 60 days, still with significant gait impairment (Rankin 4).

Correspondence: Juliana Alencar Isacksson Vieira; Email: julianaisacksson17@gmail.com.

Background: Unspecified Cerebrovascular Accident (UCA) is a condition where it is not possible to determine the classification between the types of strokes, which may have been caused by an anoxic-ischemic condition - encephalic vasogenic failure leading to lack of supplies to the brain - or hemorrhagic. Furthermore, this condition is included in the list of "garbage "codes (GC), which refer to causes of death not considered primary or those that are intermediate, terminal, or undefined. Epidemiological evidence indicates that the northern region of Brazil has a high incidence of UCA cases. Therefore, it is important to analyze the epidemiological profile of these cases to contribute to the prevention of prevalent risk factors. **Objective:** To analyze the profile of deaths and the mortality rate in the last five years of the population in the northern region affected by unspecified ischemic or hemorrhagic cerebrovascular accidents. **Methods:** This is a descriptive and quantitative study, in which secondary data were selected from the Hospital Information System of the Ministry of Health (SIH/SUS) through the Department of Informatics of the Unified Health System (DATASUS). The following resources were analyzed: mortality rate and number of deaths, according to age group, color/race, sex, and unit of the Federation. **Results:** During the period from 2019 to 2023, 7,536 deaths from UCA were reported in the northern region. Among these, the most affected age group was 80 years or older (29.15%), as expected, with a prevalence of males (52.87%) and brown people (70.60%). Notifications increased during this period, with a slight decrease in 2020, probably due to underreporting because of the Covid-19 pandemic, and peaked in 2023 (22.87%). The state with the highest occurrence was Pará (PA) with 4,076 deaths (56.96%), followed by Amazonas (AM) with 1,020 (13.53%). Another relevant data point is the mortality rate, with 2019 having the highest coefficient of 17.64, with a prevalence in females (16.56), the age group of 80 years or older (22.48), and race/color with close data between whites and blacks (19.54 and 19.53 respectively), in the 2019-2023 interval. Additionally, the states with the highest mortality rates during this period were Amapá (AP) (21.62) and Acre (AC) (19.76). **Conclusion:** Therefore, between 2019 and 2023, unspecified ischemic or hemorrhagic cerebrovascular accidents had the highest number of deaths among elderly people over 80 years old, males, and brown people,with the highest notification in the state of Pará and a peak in 2023. Furthermore, concerning the mortality rate, the most prevalent profile was also among the elderly over 80 years old, however, females and with a slight discrepancy between whites and blacks, having the highest coefficient in the state of Amapá. Thus, it is extremely relevant for public health to recognize this epidemiological profile to contribute to effective prophylactic measures for this disease.

Ischemic stroke as a diagnostic key for takayasu's arteritis: case report

João Pedro Matos de Santana[1], Allefy Beltrão Albano[1], Bruno Henrique Carneiro Costa Filho[1], Evelliny Gomes da Silva[1], Fabrício Martins Veras[1], Letícia Klabinske Marques Monteiro[1], Luísa Couceiro de Albuquerque Macêdo[1], Víctor de Moraes Chagas[1], José Luiz de Miranda Coelho Inojosa[1]

[1]Universidade Federal de Pernambuco, Hospital das Clínicas, Recife PE, Brazil.

Correspondence: Allefy Beltrão Albano; Email: allefymed@gmail.com.

Case presentation: A 27-year-old woman with recurrent episodes of fever, holocranial headache and high blood pressure since childhood, which presents with a sudden event characterized by speech changes associated with reduced strength and sensitivity in the right side that occurred in 2023. Admitted to a health care service emergency after 4 days from the onset of symptoms. She denied a similar condition and relevant family history. There are reports of four cardiorespiratory arrests during surgical procedures. On physical examination, presents asymmetry of brachial pulses, dysarthric speech, right central facial paralysis, proportional hemiparesis on the right associated with tactile hemihypoaesthesia, hemihypopalesthesia and ipsilateral heightened reflexes. Magnetic Ressonance imaging of the brain showed ischemic nucleocapsular area on the left and pons on the right, besides to angiography showing dissection of the left carotid bulb and occlusion of the right subclavian artery. In addition, there is a CT angiographic study with fusiform ectasia of the abdominal aorta and stenosis of the renal arteries with sequelae retraction of the bilateral renal parenchyma. Laboratory tests showed changes in renal function (GFR 45ml/min), negative rheumatological tests, without other findings. In this context, she was diagnosed with Takayasu's Arteritis (TA) and started treatment with Methotrexate weekly. In the onset of 2024, there were transient episodes of worsening strength in the right side of the body and rotational vertigo, with improvements occurring after a few minutes. She was admitted again for investigation and the occurrence of a transient ischemic attack represented the main occurrence suggested, considering the general clinical context and stability of the changes in neuroimaging. **Discussion:** TA is an inflammatory vasculopathy of large vessels that usually has an insidious course, with a higher prevalence in young women and asiatic population. The distribution of vascular involvement differs between sexes, with greater involvement of the abdominal aorta in men and the aortic arch in women. It is estimated that neurological manifestations such as headache and dizziness affect up to half of patients, with stroke/TIA occurring in a minority of cases (10-20%). In the present report, the patient already had long-standing symptoms, however the onset of the ischemic event corresponded to the starting point for investigation and adequate treatment of the underlying disease. **Final comments:** Takayasu's arteritis is a challenging condition considering that the presence of initial non-specific symptoms causes a delay in diagnosis and a worse clinical outcome. Therefore, it is necessary to raise such a differential diagnosis, especially in the case of stroke in young patients without established cardiovascular risk factors.

Ischemic stroke due to free-floating internal carotid thrombus in a patient with COVID-19: case report

Daniel Lacerda da Costa[1], Gisela Tinone

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Daniel Lacerda da Costa; Email: dlacerdadacosta@gmail.com.

Case presentation: A.C.S, 53 years old, female, has a history of type 2 diabetes mellitus and was taking metformin. On June 21, 2022, the patient developed a sudden onset of weakness in the right side associated with dysarthria. Upon arriving at our institution, the patient was already outside of the window for reperfusion therapies (intravenous and mechanical thrombectomy), and investigation and clinical management were chosen. On physical examination, the patient had a drop in the deficit maneuvers of the right side. The patient underwent a head CT upon admission, and the angiotomography showed a free-floating thrombus of the left internal carotid artery. Per institutional protocol, a PCR for COVID-19 was requested during hospitalization, with a positive test result. Cardiac investigation, serology, rheumatological examinations and investigations for thrombophilia were all negative. Anticoagulation was performed with enoxaparin 1mg/kg every 12 hours for 15 days, and control Doppler ultrasound showed no changes. She was discharged asymptomatic with 100mg aspirin and 40mg atorvastatin. **Discussion:** Free-floating thrombi (FFT) are defined as clots attached to the arterial wall with blood surrounding the thrombus. They are considered infrequent causes of stroke (1.6% of ischemic stroke and TIA cases combined), and the majority of cases are symptomatic (92%). Regarding the natural history of FFT, potential outcomes include progression to occlusion, distal embolization, stabilization, or disappearance. Underlying atherosclerosis is the most common cause. During the COVID-19 pandemic, reports of an increase in cases emerged, especially in mild cases, in patients with relatively healthy vessels. Thrombophilia related to COVID-19 could be one of the reasons to justify the events. Various antithrombotic approaches (anticoagulants, antiplatelet agents and fibrinolytics) and early or late carotid interventions (endarterectomy, bypass, thrombectomy and stent) have been performed. However, neither medical nor surgical treatment was clearly superior to the other. In the patient's imaging control on the 15th day, the Doppler ultrasound revealed no changes, in line with what has been reported in the literature of cases of patients who had a stroke with relatively healthy vessels. **Final comments:** Stroke related to FFT is an uncommon etiology. Before the pandemic, the reported cases had atherosclerosis as the main underlying cause, and during the pandemic there was an emergence of cases with relatively healthy vessels. Thrombophilia related to COVID-19 is one of the justifications. The treatment of this condition is very diverse in different services, with many preferring anticoagulation. In the case described here, the patient had mild symptoms and underwent anticoagulation with enoxaparin for 15 days, with the thrombus disappearing on imaging control. The patient was discharged asymptomatic, as is the case in most cases of FFT-related strokes.

Ischemic stroke in young adult and left ventricular non-compaction cardiomyopathy: a case report

Bárbara Borges de Oliveira[1], Brenda Letícia Lopes Batista[1], Victor Souza Torres de Vasconcelos[1], Yanne Almeida Aguiar[1], Ana Carolina Paiva Farias[1], Mariana Holanda Gameleira[1], Rosevaldo Alves Júnior[1], Monique Evelyn Mendonça do Nascimento[1], Renato de Amorim Guedes[2], Ana Rosa Melo Correa Lima[1]

[1]Hospital da Restauração, Recife PE, Brazil. [2]Procape, Recife PE, Brazil.

Correspondence: Bárbara Borges de Oliveira; Email: barbaraborgesneurologia@gmail.com.

Case presentation: A 23-year-old male patient presented with right-sided weakness and inability to speak for 2 days. He had no known previous comorbidities (cardiovascular, thrombophilia or immunocompromised). A brain CT scan revealed a decrease in density in the left middle cerebral artery area, as well as the nucleocapsular and periventricular regions. Doppler ultrasound of the carotid and vertebrate arteries showed no significant abnormalities, and viral sorologies were negative. However, a transesophageal echocardiogram revealed left ventricle dilatation and a region of non-compacted myocardium in the apical lateral and apical inferior segments, meeting the criteria for non-compacted myocardium. As a result, the patient was started on warfarin for anticoagulation. **Discussion:** Left ventricular non-compaction is a rare cardiomyopathy affecting the left ventricle, in which the two-layered myocardium has a non-compacted, abnormally thick, sponge-like trabecular layer and a thinner, compacted myocardial layer. This disease may not be considered an independent risk factor for stroke, but it should be remembered as a condition that may be associated with the risk of cardiac embolism and other additional cardiovascular abnormalities. Therefore, the risk versus benefit of starting oral anticoagulation in the absence of atrial fibrillation should be weighed up, bearing in mind that the incidence of stroke in non-compacted cardiomyopathy is around 10-15%. **Final comments:** His deficits gradually improved after he was monitored by motor physiotherapy and speech therapy. He was discharged from hospital with advice to maintain regular INR control, as well as outpatient follow-up with neurology and cardiology.

Ischemic stroke secondary to dissection of the right common carotid artery resulting from clamping during pre-hospital care for a stab wound in cervical zone II

Caroline Dresch Sabadin[1], Marcos Henrique Lima Galles[1], Jordana Martins Américo de Souza[1], Leonardo Kenzo Cury Nogata[1], Isabella Maria de Almeida Goulart[1], Laura Bergenthal[1], Gabriella Colodel Bazzi[1] , Júlia Bortolozzo Cazari[1], Marcius Benigno Marques dos Santos[1]

[1]Universidade Estadual do Oeste do Paraná, Cascavel PR, Brazil

Correspondence: Caroline Dresch Sabadin; Email:

Carotid artery dissection (CAD), a rare complication of penetrating cervical vascular trauma, results from the laceration of the tunica intima or the rupture of the vasa vasorum, leading to bleeding within the tunica media and the creation of a false lumen, with one of its main consequences being ischemic stroke (IS). We describe a case of IS secondary to CAD resulting from clamping of the right common carotid artery (CCA) in a young, healthy patient with no history of cerebrovascular disease. **Case presentation:** The patient is a 26-year-old female, a victim of a 10-centimeter transverse stab wound in the right anterior cervical region (zone 2), managed via clamping of the right CCA during pre-hospital care. On initial examination, she presented with a Glasgow Coma Scale score of 15, no deficits, patent airways, and no other abnormalities. She underwent surgical treatment consisting of ligation of the internal jugular vein and suture of the CCA's adventitia layer. The postoperative period was managed in a hospital setting with antiplatelet therapy using acetylsalicylic acid and prophylactic anticoagulation with full heparinization. Follow-up cranial CT images showed a hypodense area in parts of the right middle cerebral artery territory, consistent with IS. Eco Doppler highlighted a 1.0-centimeter discontinuation in the intima layer of the CCA. After sixteen days of hospitalization, the patient developed left hemiparesis and grade III muscle strength in the left upper limb, with other neurological examinations remaining unchanged. **Discussion:** Penetrating cervical injuries account for 5 to 10% of traumas, with the most common mechanism being stab wounds. Arterial involvement occurs in 25% of cases, primarily affecting the carotid artery (80%). **Final comments:** Given the above, appropriate pre-hospital care is crucial for a favorable clinical outcome, as the mortality rate for penetrating cervical injuries can reach 10%. Bibliographic data suggest simple external compression or tamponade with a Foley catheter as an initial approach for cervical hemorrhages. Clamping of the CCA should be avoided as it may increase the risk of dissection, which accounts for 2% of all IS cases.

Ischemic stroke with bilateral internal carotid artery dissection in a 30-year-old woman: a case report

Giovanna Nina Ueda[1], Maria Eduarda Cosme Bongiovani[1], Juliana Alcântara Brugnoli[1], Laura Bianchini Fogulin[1], Alice Jardim Zaccariotti[1], Matheus Spilari[1], Raíssa Cariello[1], Mayko Nascimento Merscher[1], Wagner Mauad Avelar[1], Danilo dos Santos Silva[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Giovanna Nina Ueda; Email:

Case presentation: A 30-year-old woman, with no prior medical history, undergoing uterine preparation therapy for her second attempt at in vitro fertilization, and previous episodes of paresthesia in the right upper limb, presented with acute onset headache, that progressed to reduced verbal fluency and decreased grasp force in her right upper limb. She had partial recovery and a week later had another event, this time associated with aphasia, right facial palsy and right upper limb paresis. Computed tomography and Magnetic resonance imaging indicated acute ischemic injury in the territory of the left middle cerebral artery. There was also reduced flow-void of the intracranial left internal carotid artery on MRI. Angiotomography suggests a bilateral internal carotid artery dissection (ICAD), which was then confirmed with arteriography. Double antiplatelet therapy was started and, after two months, mild right facial palsy and expression aphasia were noted. **Discussion:** Carotid artery dissection, a tear in the intimal layer of the artery with intramural thrombus, is the leading cause of ischemic stroke in individuals under the age of 50. Most ischemic strokes from dissections actually occur in the extracranial carotid and vertebral arteries, potentially blocking the artery or causing distal embolism due to cervical traumas or even relatively minor actions such as coughing or sneezing. When no major traumatic event is evident, ischemic stroke is typically attributed to spontaneous carotid artery dissection (SCAD). Most SCAD cases are unilateral, while bilateral dissections are rare, accounting for about 10% of all patients and the exact causes remain unknown. Nevertheless, certain factors, such as migraines, hypertension, smoking, and the use of oral contraceptives, are associated with an increased risk of dissection. Additionally, connective tissue and collagen diseases like fibromuscular dysplasia, Ehlers-Danlos syndrome and Marfan's syndrome can predispose to SCAD, even when minor trauma is present, indicating that these conditions may render the blood vessels more susceptible to injury. However, these disorders are rarely identifiable with current tests, as screening for underlying connective tissue disorders is not routinely conducted. **Final comments:** We encountered a bilateral ICAD case in a 30-year-old woman. Simultaneous spontaneous dissections of both carotid arteries are rarely reported but represent a noteworthy cause of ischemic stroke, especially in young patients, even with minor trauma.

Isolated conus medullaris infarction: a case report

Gabriel Abrahão Stoliar[1], César Minoru Toita Koga[1], Valmir Vicente Filho[1], Francisco Manoel Branco Germiniani[1], Valéria Cristina Scavasine[1], Caio César Diniz Disserol[1,2,3]

[1]Universidade Federal do Paraná, Hospital de Clínicas, Curitiba PR, Brazil.
[2]Instituto de Neurologia de Curitiba, Curitiba PR, Brazil.
[3]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Gabriel Abrahão Stoliar; Email: gabrielstoliar@gmail.com.

Case presentation: Female patient, 62 years old, hospitalized for treatment of acute chronic kidney disease, awakens in the morning with weakness of the lower limbs associated with reduced sensitivity, with an acute evolution. She had an episode of hypotension prior to the event. He presented with symmetrical paraparesis (strength grade 1/5 bilaterally), tactile, painful and vibratory hypoesthesia with a sensory level at L1-L2. She progressed with urinary and fecal retention in the following days. She had undergone cardiac catheterization via the femoral artery 3 months before the current situation. On magnetic resonance imaging of the thoracic and lumbosacral spine, hypersignal was observed on T2/FLAIR at the level of the conus medullaris, with restricted diffusion on DWI. Angiotomography of the chest and abdomen demonstrated the presence of significant atherosclerotic disease throughout its extension, with the presence of ulcerated plaques at the level of the affected topography. **Discussion:** Spinal cord infarction represents approximately 1% of strokes and 6 to 8% of acute myelopathies. Conus medullaris infarction is particularly rare, but potentially disabling, and may cause impairment in ambulation and sphincter control. Isolated infarcts of the conus medullaris are rare events, being described in the literature only in case reports and small case series. Due to the adequate blood supply to the conus medullaris through this artery and anastomosis of the anterior and posterior spinal arteries, injuries of this nature to the conus medullaris are uncommon. Clinically, it presents with acute or sudden back pain associated with bilateral sensory deficits, motor and sphincter deficits, the latter of which can develop within 12 hours. Its main etiology is atherosclerosis, as well as fibrocartilaginous embolism, vasculitis and surgical procedures in the aorta. Arterial hypertension was demonstrated as the main risk factor. Magnetic resonance imaging is useful for diagnosing spinal cord infarction. It can reveal abnormalities within approximately 3 hours of the onset of symptoms, and is recommended as it assists in appropriate treatment, reducing neuronal death and subsequent neurological deficits. **Final comments:** Isolated conus medullaris infarction is a rare entity that can be extremely disabling. Its etiology is mainly related to atherosclerosis and aorta procedures. Early clinical identification and diagnostic confirmation through neuroimaging examination are essential to prevent impairment to the patient.

Isolated oculomotor nerve palsy, stroke and syphilis: a reported case

Renan Macionil Cotrim[1], João Márcio Borgue de Oliveira[1], Itamar Meireles Andrade Santos[1], Rebeca Aranha Barbosa Sousa[1], Ana Beatriz Marangoni Baston[1], José Eduardo Trentim Longo[1], Pedro Machry Pozzobon[1], Natália Cristina Ferreira[1], Rodrigo Bazan[1], Laura Cardia Gomes Lopes[1]

[1]Universidade Estadual Paulista, Botucatu SP, Brazil.

Correspondence: Renan Macionil Cotrim; Email: renan.cotrim@unesp.br.

Case presentation: A 68-year-old man experienced sudden onset of bilateral ptosis, more pronounced on the left, along with horizontal and painless binocular diplopia. Neurological examination revealed left-sided paresis of the medial rectus, superior rectus, and inferior rectus muscles, as well as bilateral ptosis, worse on the left. There were no pupillary abnormalities, cranial nerve deficits, or involuntary movements noted. Arterial CT angiography showed redundancy in the left posterior cerebral artery and stenosis in the right, with a soft plaque detected in the middle third of the basilar artery. Brain MRI identified an ischemic lesion with restricted diffusion in the left paramedian mesencephalic region. During the investigation into the stroke's cause, serological testing confirmed syphilis, accompanied by hyperproteinorrachia in the cerebrospinal fluid analysis. The patient was treated for neurosyphilis with crystalline penicillin 4 million IU every 4 hours for 14 days. Consequently, the patient's condition was classified as TOAST undetermined due to two potential causes: intracranial stenosis from the basilar artery plaque and meningovascular syphilis. Upon discharge, the patient received dual antiplatelet therapy and a high-potency statin. **Discussion:** Isolated oculomotor nerve palsy is rare, with limited national studies available. A population-based study conducted in Olmsted County, United States, from 1978 to 2014 reported an overall incidence of acquired third nerve palsy of 4.0 per 100,000 (95% CI, 3.3-4.7), with higher rates in those over 60 years old. Ischemic neuropathy is the primary cause in adults, but investigations should consider other etiologies causing acute clinical manifestations such as stroke. Although involvement in this neuroanatomical region typically results in additional neurological deficits, such as choreoathetotic movements and contralateral upper limb tremors with red nucleus involvement, the patient presented an atypical course without additional deficits on admission. **Final comments:** Isolated third cranial nerve palsy, though uncommon, warrants consideration of various etiologies. A comprehensive clinical history and neurological examination are crucial for accurate diagnosis. Despite the prevalence and comorbidities suggesting ischemic neuropathies in adult patients, thorough investigation into less common causes is essential for precise diagnosis and treatment planning.

Isolated oculomotor nerve paralysis after mild traumatic brain injury

Emanuelly Victória Andrade Fonseca[1], Gustav Barbosa Falcão[1], Luma Santos de Oliveira[1], Kézia de Souza Pinheiro[1], Melissa dos Santos Matos[1], Igor Flavio Gonçalves do Vale[1], Daniel Mariani Favalessa[1], Bruno Vasconcelos Sobreira Guedes[2], Marina de Angeli[2], Bruno Batitucci Castrillo[2]

[1]Universidade Federal do Espírito Santo, Vitória ES, Brazil.
[2]Hospital Universitário Cassiano Antonio Moraes, Vitória ES, Brazil.

Correspondence: Emanuelly Victoria Andrade Fonseca; Email: mn.andradeduarte@hotmail.com.

Case presentation: A 37-year-old woman was involved in a motorcycle accident with head trauma while wearing a helmet in July 2023. She reported post-traumatic amnesia for 3 hours without loss of consciousness. She related difficulty to open her left eye and diplopia. She denied ethylism, smoking and other comorbidities. Physical examination revealed complete left ptosis, divergent strabismus, absence of ocular elevation, depression and adduction in the left eye, anisocoria with fixed mydriasis in the left eye. Cranial resonance imaging showed pathological enhancement of the left 3rd cranial nerve (CN III), from the interpeduncular fossa to the lateral wall of the left cavernous sinus, along the entire cisternal pathway, configuring isolated neuropathy of the left NC III after trauma. The serology was negative for infectious causes. The diagnosis of left oculomotor nerve traumatic neuritis was confirmed with clinical data, physical examination and neuroimaging. Prednisone was prescribed for 1 month with partial improvement and slight opening of the palpebral rima. **Discussion:** The CN III is divided into 4 segments: fascicular, cisternal, cavernous and orbital. Its general somatic efferent fibers arise from the oculomotor nerve nucleus and general visceral efferent fibers from the Edinger-Westphal nucleus, located at the level of the superior colliculus in the brainstem. It has an apparent origin in the interpeduncular fossa, penetrates the cavernous sinuses and enters the orbit through the superior orbital fissure. Isolated palsy of the CN III can be complete, when all voluntary movements are absent, resulting in exotropia, diplopia, ptosis, or incomplete, when it affects part of the muscles innervated by the CN III. The pupil can be involved with an enlarged and nonreactive pupil (mydriasis). The main causes in adults are ischemia,

aneurysm, neoplasm and trauma, with only 10% being traumatic etiology. Isolated involvement of the CN III by traumatic brain injury (TBI) that is not caused by mass effect lesions, such as subdural or extradural hematomas, is rare, especially in mild TBIs. Pathogenic mechanisms leading to this outcome can be direct (abnormal nerve stretching from high kinetic energy trauma, compression by adjacent structures altered by injury, such as a pseudoaneurysm) or indirect (mainly ischemia from immediate vascular changes or metabolic alterations post-trauma). Our case shows a woman with isolated CN III palsy after mild TBI. The etiological hypothesis is distension and contusion of the left CN III at the posterior petroclinoid ligament, due to movement of the brainstem and consequent axonal stretching during the impact. **Final comments:** In conclusion, the case highlights a rare but significant neurological complication following mild traumatic brain injury, emphasizing the importance of detailed clinical evaluation, imaging, understanding of anatomical and pathophysiological aspects in managing such cases effectively.

Isolated ophthalmoplegia in a patient with Miller-Fisher syndrome

Luísa Stradioto Sartor[1], Maysa Rebelo Crestani[2], Pietro Turella[3], Tanisi Rebelo Crestani[1], Fabrício Diniz Kleber[1]

[1]Universidade de Caxias do Sul, Caxias do Sul RS, Brazil.
[2]Universidade do Sul de Santa Catarina, Tubarão SC, Brazil.
[3]Universidade do Oeste de Santa Catarina, Joaçaba SC, Brazil.

Correspondence: Luísa Stradioto Sartor; Email: lssartor@ucs.br.

Case presentation: A 34-year-old male patient was admitted to the hospital due to sudden onset diplopia. The initial neurological examination shown bilateral ophthalmoplegia suggestive of III nerve palsy, associated with mydriasis, dysarthria, and paresthesia on the left side of the face. The first impression of the attending neurologist was a brain stem syndrome with internuclear ophthalmoplegia due to the sudden onset of symptoms. Gradually, during the first 10 days of hospitalization the patient developed complete paralysis of the extrinsic ocular muscles and started with bilateral facial palsy and worsening of the dysartria, the reflexes were also widespread decreased. There was no significant ataxia on examination. The investigation progressed with a lumbar puncture and electroneuromyography that shown elevated protein with normal cellular counts on the cerebrospinal fluid and alterations suggestive of Miller Fisher syndrome on the electroneuromyography. Treatment with Intravenous Immunoglobulin was administered with some improvement of the facial palsy at discharge from hospital. Physical examination at discharge showed mild left facial paresis, mild dysarthria, and he continued with the bilateral ophthalmoplegia, worst on his left side. At follow-up revision by phone the patient stated that he has improved considerably, but remaining with the ophthalmoparesis. **Discussion:** The Miller-Fisher syndrome (MFS) is usually a rare syndrome characterized by the classical triad: ophthalmoplegia, ataxia and areflexia. It is considered a variant of the Guillain-Barré syndrome, with incidence worldwide around 1-2 cases each 100.000 people. Typically it presents with the acute or subacute onset of the triad, starting with the ophthalmoplegia, diplopia, following with ataxia and generalized areflexia. The diagnoses is usually made by the presence of elevated proteins in the cerebrospinal fluid and electroneuromyography typical findings, and we can also identify the presence of anti-GQ1b IgG antibodies on the cerebrospinal fluid. At the present case we do not have this test available what the public system. The GQ1b antibody is thought to have a direct effect on the neuromuscular junctions of the ocular muscles. The GQ1b ganglioside is also an important component of oculomotor nerve myelin. In the afore mentioned case it is remarkable the unusual presentation of hyper acute symptoms with the association with marked mydriasis at the onset. There was no significant ataxia or gait abnormalities at the onset. Furthermore, it is uncommon for the patient with MFS to present with an hyperacute onset associated with mydriasis and paresthesias. **Final comments:** The case report related here, shows a rare presentation of the MFS. It elucidates a rare presentation of a variant of GBS, that is an important cause of diplopia and ophthalmoplegia caused by a demyelinating peripheral nerve autoimmune desease that could affect the young population.

https://doi.org/10.5327/CBN241003

Isolated optic neuritis: an atypical manifestation of bartonellosis

Amanda Carvalho de Oliveira[1,2], Lucas Leroux de Ricchezza[2], Marcela de Moraes Serpa[2], Marco Antonio Sales Dantas de Lima[1], Carolina Rouanet[1,2], Nayane Gentil[2], Rosa Batistella[2], Vinicius Soares[2], Luciane S. Oliveira[2]

[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro RJ, Brazil.
[2]Hospital Copa D'or, Rio de Janeiro RJ, Brazil.

Correspondence: Amanda Carvalho de Oliveira; Email: amanda-c16@hotmail.com.

Case presentation: A 49-year-old female experienced an acute onset reduction of visual acuity in her right eye, with a predominantly central scotoma, which progressively worsened over seven days, accompanied by pain on eye movement. She also reported daily chills and headaches over the past month. She had a relevant history of being scratched by a rescue kitten two months before her first evaluation. The kitten passed away a few days later without a known cause. Neurologic examination was notable for perception of movement only in her right eye. Fundoscopic examination showed right optic disc (OD) edema without retinal changes. During her hospital stay, she consistently had elevated serum inflammatory markers (ESR and CRP) and daily low-grade fever of unknown origin. MRI showed mild optic nerve (ON) sheath distension, right ON tortuosity, bulginig of the right nerve optic disk, contrast enhancement of the ON-globe junction, and restricted diffusion of the right OD. CSF workup showed 42 white blood cells with lymphomononuclear predominance. She was started on doxycycline, rifampin, and prednisone for suspected bartonellosis with CNS involvement, with gradual improvement of symptoms, ESR, and CRP. On day 15 of her hospital stay, serum IgG and IgM for bartonellosis came back positive, and the patient was discharged for outpatient follow-up. A repeat MRI two weeks after discharge showed significant improvement. **Discussion:** Cat scratch disease is a systemic disease caused by Bartonella henselae, acquired through scratches, bites, or exposure to fleas from infected cats, and mostly causes mild systemic symptoms in immunocompetent individuals. Neuroretinitis is a rare manifestation of the disease (1-2%) and causes acute unilateral visual loss due to OD edema and macular exudates, which are often star shaped, but it can take weeks to appear. Other possible neurologic manifestations include encephalopathy, transverse myelitis, radiculitis, and cerebellar ataxia. We report a case of isolated optic neuritis initially seen in an ophthalmologic emergency unit, which identified OD edema and transferred the patient for suspected autoimmune disease. However, a history of fevers and chills and persistently elevated serum ESR and CRP led us to withhold immunosuppressive treatment and focus on a potential infectious etiology. The patient's history of being scratched by a kitten two month before and characteristic optic disk bulging seen at MRI led us to start empiric treatment for neurobartonellosis while awaiting serologic confirmation. **Final comments:** This case highlights the importance of considering infectious etiologies of isolated optic neuritis, especially in the presence of warning signs such as fever and elevated inflammatory markers, as high-dose corticosteroids may worsen such cases. Additionally, it underscores the need to consider cat scratch disease even without the characteristic stellate macular exudate and retinal changes.

Isquemic stroke concomitant with pulmonary thromboembolism: when to anticoagulate ?

Lucas Rodrigues Prim[1], Ana Paula Gonçalves Barankiewicz[1], Maria Julia Branco Rodrigues[1], Marcos Seefled[1], Lisseth Fabiola Vallejo Reyes[1], Frederico Otto Flores Moraes[1], Eduardo Takahashi Sunaga[1], Joao Pedro Greca de Macedo Biasi[1], Gustavo Schneck de Jesus[1], Vitor Bonk Rizzo[1]

[1]Hospital Universitário Evangélico Mackenzie, Curitiba PR, Brazil.

Correspondence: Ana Paula Gonçalves Barankiewicz; Email: anapaulaapgs@gmail.com.

Case presentation: A 69-year-old woman with no comorbidities presented to the Emergency Department (ED) on April 29th for a suspected stroke. Family members who witnessed the episode reported that she had a same-level fall at home in the morning, followed by right-sided hemiparesis, leftward gaze deviation, and global aphasia. On admission, her NIH Stroke Scale (NIHSS) score was 18, with a time of evolution of 1 hour and 19 minutes. She received thrombolysis due to the absence of contraindications. Her general condition was poor, with a blood pressure of 140/81 mmHg, heart rate of 78 bpm, respiratory rate of 18 breaths per minute, and oxygen saturation of 87% on room air, requiring supplemental oxygen via a nasal cannula. Neurological examination revealed global aphasia, right hemineglect, right lower limb plegia, and grade 1 weakness in the right upper limb with global hyporeflexia. An admission CT angiogram showed a left M1 occlusion. The cranial computed tomography (CT) scan had an ASPECTS score of 10 and also revealed bilateral pulmonary embolism (PE) in the peripheral pulmonary arteries. A follow-up CT scan 24 hours after thrombolysis showed evidence of bleeding without NIHSS change, consistent with ECASS-PH 1. Anticoagulation with enoxaparin was initiated on May 1st due to the risk of cardiogenic shock from PE. A subsequent cranial CT revealed intraparenchymal hemorrhage in the left basal ganglia with surrounding hypodense edema, compression of the left lateral ventricle, and hyperattenuating material suggestive of hematoma. There was a midline shift to the right (5 mm). On May 10th, the cranial CT showed reduced areas of hemorrhagic transformation and decreased intraventricular hematoma. The patient's consciousness level improved (Glasgow Coma Scale score of 10), but she continued to have right hemiplegia and global aphasia. She was not using supplemental oxygen and had no desaturation, and she was referred for rehabilitation and outpatient follow-up. **Discussion:** Stroke is highly prevalent and a leading cause of mortality in Brazil, ranking second in women and third in men. Similarly, PE is common, with a prevalence of up to 16.6% and mortality rates of up to 30%. The occurrence of concurrent PE and ischemic stroke (IS) is rare, lacks clear therapeutic guidelines, and poses treatment challenges. Anticoagulation for PE is typically contraindicated in IS patients receiving thrombolysis due to an increased risk of bleeding. Clinically, the simultaneous presence of neurological deficits and respiratory symptoms should raise concern. **Final comments:** Simultaneous PE and IS is extremely rare but has a significant impact on patient health. Although guidelines do not recommend early resumption of anticoagulation after thrombolysis in IS patients, the risks and benefits should be evaluated in cases of concurrent PE. Interdisciplinary assessment and treatment decisions are essential in this clinical context.

James Parkinson's legacy on child abuse two centuries after his passing.

Emanuelle Campos Amaral[1], Fernanda Almeida Carvalho[1], David Franca Ferreira Cruz[1], Maria Esther Lima Rios Evangelista[2], Danilo Lemes Reis[1], Manuela Brandao Ferreira Teles[1], Victor Hugo Soares dos Santos[1], Samuel Natal Rodrigues[1], Diogo Rabelo de Lima[1], Marcus Vinicius Della Coletta[1]

[1]Universidade do Estado do Amazonas, Manaus AM, Brazil.
[2]Universidade Federal do Amazonas, Manaus AM, Brazil.

Correspondence: Emanuelle Campos Amaral; Email: eca.med22@uea.edu.br.

Background: Well-known English doctor James Parkinson is credited with providing the initial explanation of Parkinson's disease. He was influential in the development of the present specialty of pediatrics because, despite his extensive study in the field of neurology, he was interested in the healthcare, safety, and protection of children. He was a significant figure in many fields, studying fossils, geology, medicine, politics, and raising awareness of child abuse and its harmful effects on children's health. **Objective:** The primary goal is to draw attention to James Parkinson's importance in the battle against child abuse, because he was among the first medical professionals to speak out about the problem. **Methods:** The methodology was a systematic review based on 3 articles found on Scopus, Scielo and PubMed, to highlight his significance outside of the medical field. The inclusion criteria were articles that included the terms "James Parkinson", "child" and "abuse" in the title or in the abstract. The exclusion criteria were inappropriate methods and articles that emphasized his accomplishments in different fields. **Results:** James Parkinson noticed the abusive behavior when he began to connect head injuries, primarily from falls, with the development of hydrocephalus or "watery head". After seeing a case of child abuse, that he detailed in his 1804 pamphlet "The Villager's Friend and Physician", he noticed that another major contributing factor to hydrocephaly was improper child discipline, in which parents would strike their children severely in the head. Consequently, following the aggressive conduct, the youngster would complain of typical hydrocephaly symptoms, like cephalalgia, restless sleep, nausea and fever. He wrote the book "Medical Admonitions to Families" in 1807 to warn the public, in which he candidly said that the parents' inappropriate educational methods were the root of many health problems. He labeled those actions as child abuse and emphasized that, to properly correct someone, there must be mercy and open communication, not suffering and terror. He openly spoke about different and improved ways to educate children, defying the habits of the nineteenth century. Furthermore, he explained that the fear experienced during these violent acts would result in mental illnesses. **Conclusion:** In summary, it is evident that Parkinson acted outside of the Neurology field, with accomplishments beyond the description of Parkinson's disease, which had positive impacts, even 200 years after his death. He was ahead of his time in recognizing the negative effects of this kind of maltreatment on a child's development and health. It was a tremendous move for him to openly address the matter and share his opinions, starting a conversation that would result in future rights enforcement and protection for this vulnerable group as well as avoid any psychological and physical harm.

Journey of value of raras (JAV RARAS): cost analysis of the treatment of amyotrophic lateral sclerosis (ALS) using the time-driven activity-based costing (TDABC) methodology in a specialized service in Salvador-Bahia

Laís Brandão Mota[1], Luna Souza Silva Vilanova[1], Maria Rodrigues Lima de Souza Pessoa[1], Stefania Zingone Andrade Carvalho[1], Temis Maria Felix[2], Marcela Câmara Machado Costa[1], Marilaine de Matos Menezes Ferreira[1], Camila Azevedo[3], Marcelo Nita[3], Thiago Belina[3]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.
[2]Hospital de Clínicas de Porto Alegre, Porto Alegre RS, Brazil.
[3]MAPES Solutions, São Paulo SP, Brazil.

Correspondence: Laís Brandão Mota; Email: bmota.lais@gmail.com.

Background: Amyotrophic lateral sclerosis (ALS) has many ongoing research efforts and multidisciplinary care initiatives aimed at improving the management of this disease. In this context, the Time-Driven Activity-Based Costing (TDABC) methodology has proven to be an effective approach for healthcare organizations to obtain an accurate view of the care process and the costs associated with the services provided. The use of TDABC allows for the identification of costly activities, enabling the optimization of processes and the reduction of costs without compromising the quality of patient care. This approach is crucial for supporting decisions and efficiently allocating resources in the treatment of rare diseases such as ALS. **Objective:** To quantify the costs related to the treatment of ALS in a specialized service in Salvador, Bahia, using the TDABC method and to contribute to a more detailed understanding of the annual cost of care for patients with ALS. **Methods:** This study describes the implementation of the TDABC methodology in the rare disease care journey (JAV RARAS). Cost data were collected through interviews and surveys with administrative, nursing, and healthcare professionals from the institution. Direct costs were analyzed by identifying activities in disease management, allocating consumed resources, estimating the cost per unit, and measuring activity time. Additionally, the study allowed for the validation of protocols that cover the care journey of patients with rare diseases, contributing to a more accurate understanding of the annual cost of care. **Results:** The average annual cost per patient with ALS is $7.506.20. Most of this value, $7.238.15, is dedicated to the treatment itself. The main cost components are human resources ($1.227.46), materials ($16.43), medications ($2.252,51), tests ($138.20), procedures ($348.63), and equipment ($3.251.97). Regarding the source of financial resources, approximately 98.5% comes from the Unified Health System (SUS), while about 1.5% is funded by the institution itself. **Conclusion:** This study investigated the annual costs of ALS treatment in a specialized service. The results indicate that the average annual cost per patient is $7.506.20, with most of this value dedicated to the treatment itself. These findings highlight the importance of understanding and optimizing the use of these public resources to ensure the sustainability of the health system and equitable access to ALS treatment.

Juvenile Huntington's disease: the influence of CAG repeat number on clinical manifestations - 2 case reports

Víctor de Oliveira Costa[1], Iasmim Portela Maifrede[1], Márcio Alves da Cruz Júnior[1], Daniel Sabino de Oliveira[1], Thiago Cardoso Vale[1]

[1]Universidade Federal de Juiz de Fora, Hospital Universitário, EBSERH, Juiz de Fora MG, Brazil.

Correspondence: Victor de Oliveira Costa; Email: victordeoliveiracosta82@gmail.com.

Case presentation: Case 1: A 21-year-old woman began exhibiting heteroaggressiveness, inattention, difficulty with social interaction, and information processing at the age of 10. By 19, she developed mild appendicular bradykinesia and rigidity. At 21, she presented with upper limb bradykinesia, cogwheel rigidity in all four limbs, gait with dystonic posture of the right upper limb and lower limbs, choreiform movements of the upper limbs, and myoclonus, along with abnormal cognitive test results for her age and educational level. Behavioral evaluation revealed severe depression with previous suicidal ideation. Concurrently, her father developed aggressiveness and choreic movements. A brain MRI showed bilateral atrophy of the caudate nuclei. Both the patient and her father underwent genetic testing for Huntington's disease (HD), revealing 61 and 47 CAG repeats, respectively. Case 2: A 10-year-old male experienced difficulty sitting without support, with backward falls and right-sided imbalance while running since 7 years of age. He progressed to frequent falls associated with rhythmic involuntary movements of the right upper limb. He exhibited mild dystonic posture, bradykinesia, and backward falls in tandem. His school performance was delayed, particularly in reading. A brain MRI showed hyperintensity of the striatum and putamen, along with atrophy of the caudate nuclei and putamen. His father was diagnosed with HD at the age of 38. Genetic testing for HD revealed 79 CAG repeats. **Discussion:** Huntington's disease is characterized by motor and cognitive dysfunction, along with psychiatric and behavioral changes. Individuals with age of onset ≤20 years are considered to have juvenile Huntington's disease (JHD), accounting for 4-10% of HD patients. Juvenile forms are associated with alleles containing more than 50 CAG repeats. There is an inverse relationship between CAG repeat length and age of onset for JHD, with higher repeats indicating earlier onset and faster disease progression. Moreover, JHD is divided into those with highly expanded repeats (≥80 CAG repeats) and those with fewer repeats. Those with higher repeat counts exhibit earlier and faster symptom progression, as seen in these cases. The most common pathological change is diffuse and marked atrophy of the neostriatum, often worse in the caudate than in the putamen. There is no cure or disease-modifying treatment for HD, focusing instead on symptom management and supportive care. **Final comments:** JHD is a rare disease requiring further studies to better define its parameters and compare it with adult-onset HD for improved diagnostic approaches and therapeutic interventions.

Juvenile myasthenia gravis positive acetylcholine anti-receptor in a male child: a case report

Maria Luiza Vasconcelos Montenegro[1], Mariana Lucena Loureiro[1], Déborah Emmily de Carvalho[1], Maria Clara Arcoverde Santana[2], João Eudes Magalhães[2], Fabíola Lys de Medeiros[2]

[1]Universidade de Pernambuco, Recife PE, Brazil.
[2]Hospital Universitário Oswaldo Cruz, Recife PE, Brazil

Correspondence: Maria Luiza Vasconcelos Montenegro; Email: marialuizavasc534@gmail.com.

Case presentation: Male, 11 years old, started experiencing muscle weakness, frequent falls, and fatigue in the lower limbs (LL), associated with difficulty walking and eating, at the age of 6. He denied other complaints and had no similar family history. On neurological examination: bilateral semiptosis, ophthalmoplegia, reduced facial expression, nasal speech, normal static and dynamic balance. Grade 4 strength in the upper and lower limbs, normoactive reflexes, trophism, and muscle tone without changes. Computed tomography of the chest, to evaluate the thymus, was normal. Total creatine phosphokinase (CK) dosage was 81u/L. Electroneuromyography showed a maximum decrease of 30.1%, compatible with myasthenic syndrome. Measurement of antibodies against

acetylcholine receptors (anti-AChR), in 2019, was negative. But in the face of post-synaptic myasthenic syndrome, Mestinon (120mg/day) was prescribed. Due to the persistence of symptoms, Prednisone was added at 5mg/day, resulting in an improvement in lower limb weakness and nasal speech. In 2020, a new measurement of antibodies against the muscle-specific tyrosine kinase receptor was carried out, which was normal. In 2021, due to the persistence of bilateral eyelid semiptosis, Mestinon was increased to 180 mg/day. In 2024, a new measurement of anti-AChr antibodies was positive, with Azathioprine 50 mg/day being associated with therapy. Currently, the patient denies muscle weakness or new complaints, however, due to the persistence of bilateral eyelid ptosis and ophthalmoplegia, the doses of Mestinon and Azathioprine were increased to 210 mg/day and 75 mg/day, respectively. **Discussion:** Myasthenia gravis (MG) is a chronic autoimmune disease that affects neuromuscular transmission, leading to progressive muscle weakness and excessive fatigue. The most common form of MG is that associated with anti-AChR antibodies, which attack acetylcholine receptors at the neuromuscular junction, resulting in the characteristic muscle weakness. This symptom usually occurs mainly in the eye muscles, leading to ptosis and diplopia. The incidence of MG with positive anti-AChR antibodies is higher in adults, especially young women and older men. However, it can also occur in children and adolescents, although it is less common. The usual treatment involves the administration of anticholinesterase medications to increase the concentration of acetylcholine at the neuromuscular junction, thus improving the transmission of nerve stimuli to the muscles. Immunosuppressants may be necessary to control the underlying autoimmune response, as seen in the reported case. **Final comments:** Juvenile MG, although uncommon, is a complex condition that requires multidisciplinary and personalized management. With early diagnosis, appropriate treatment, and ongoing support, many children can achieve a good quality of life, allowing them to fully participate in everyday activities.

Kennedy disease: a case report

Antonio Marco Duarte de Albuquerque[1], Sarah Câmara Ferreira[1], Sophia Alves de França[1], Jonatas Pinto Pinheiro de Sousa[1]

[1]Faculdade de Medicina de Olinda, Olinda PE, Brazil.

Correspondence: Sarah Câmara Ferreira; Email: sarahcamaraf99@hotmail.com.

Kennedy's disease (KD), or bulbospinal muscular atrophy, is a hereditary recessive condition linked to the X chromosome. It is characterized by the degeneration of lower motor neurons, resulting in atrophy, muscle weakness, and tremors. A mutation in the androgen receptor gene is associated with the disease, leading to the expansion of CAG trinucleotide repeats. Additionally, endocrinological manifestations such as gynecomastia, testicular atrophy, and oligospermia are common. **Case presentation:** A 68-year-old male patient with difficulty walking, initially in his right foot and later affecting both feet. He presents with decreased sexual capacity and testicular atrophy. Physical examinations reveal a paraparesis gait and gynecomastia. Laboratory tests show an increase in CPK. Breast ultrasound and electromyography of the lower limbs confirm the gynecomastia and strongly suggest KD, respectively. **Discussion:** Discussion highlights that, even without access to genetic testing, it is possible to diagnose rare pathologies through clinical exams and low-cost tests. The increase in CPK may indicate myopathic changes secondary to denervation. **Final comments:** The conclusion emphasizes the importance of genetic counseling and monitoring the disease's progression in the absence of molecular diagnostic evidence.

Kennedy's disease (X-linked spinal and bulbar muscular atrophy): follow-up of 18 patients in a neuromuscular outpatient clinic

João Paulo Barile[1], Kaliny Oliveira Peixoto[1], Patrícia Marques Mendes[1], Renan Brandão Rambaldi Cavalheiro[1], Daniel Delgado Seneor[1], Igor Braga Farias[1], Paulo de Lima Serrano[1], Wladimir Bocca Vieira de Rezende Pinto[1], Paulo Victor Sgobbi de Souza[1], Acary Souza Bulle Oliveira[1]

[1]Universidade Federal de São Paulo, Setor de Doenças Neuromusculares, São Paulo SP, Brazil.

Correspondence: João Paulo Barile; Email: barile.jpaulo@gmail.com.

Background: Kennedy's disease (KD), or X-linked spinal and bulbar muscular atrophy, is a rare lower motor neuron disease associated with abnormal CAG trinucleotide repeat expansion (≥38 CAG repeats) in the AR gene. The onset of symptoms is earlier in cases with a greater number of CAG repeats. Symptoms generally begin between 30-50 years of age with slowly progressive lower motor neuron syndrome, weakness of the proximal and distal muscle groups of the upper and lower limbs, bulbar compromise with dysarthria and dysphagia, fasciculations, myokymia and postural tremor. Sensory symptoms, such as paresthesia, may be also observed. Androgen insensitivity frequently occurs leading to gynecomastia, infertility, erectile dysfunction, and metabolic disturbances (glucose intolerance, dyslipidemia). **Objective:** Present the clinical, genetic and neurophysiological aspects of an original case series of 18 patients with KD. **Results:** The average age at onset of symptoms was 44 years (25-60) and the average age at diagnosis was 50 years (38-62). The average duration of symptoms until diagnosis was 4.8 years. The main clinical complaints included: limb weakness (n=14); dysphagia (n=7); muscle fatigue (n=6); and neck weakness, hand tremors, fasciculations, and cramps (n=1, each one). Clinical course was progressive in 72.22% of cases. A positive family history was identified in 77.7% of cases. Regarding clinical involvement, the following profile was seen: proximal muscle weakness of the lower limbs with reduced tendon reflexes (n=18; 100%); tongue atrophy (n=17; 94.4%); proximal quadriparesis (n=15; 83.3%); fasciculations in the tongue n=14 (77.7%); dysphagia (n=12; 66.6%); distal tremor (n=11; 61.1%); facial diparesis (n=9; 50%); dysphonia (n=8; 44.4%); neck fasciculations (n=4; 22.2%). Ankle clonus, extensor plantar responses, spasticity and dementia were not observed in any patients. Non-invasive ventilation dependency was seen in only 11.1% of cases. Other findings observed included: gynecomastia (n=15; 83.3%), sexual dysfunction (n=4; 22.2%), hyperkyphosis or scoliosis (n=4; 22.2%), and pes cavus (n=2; 11.1%). Diabetes or pre-diabetes and dyslipidemia were seen in 44.4% of cases. Needle electromyography disclosed chronic denervation involving the bulbar, cervical and lumbosacral myotomes (n=18) as well as reduced amplitude of sensory nerve action potential (n=17). Mean serum creatine kinase levels were 772 (450-1300). Genetic testing disclosed an average value of 48 CAG repeats (44-55) in the AR gene. No significant brain and spine abnormalities were seen on Magnetic Resonance Imaging (MRI) studies. All patients used leuprorelin acetate (n=18) in their treatment. **Conclusion:** KD is a rare X-linked inherited disease with complex neurological and systemic features. Future studies are needed to develop modified disease therapies.

Ketogenic diet applied to myoclonic status epilepticus in progressive myoclonic epilepsy

Atilio Gomes Romani[1], Miriam Eva Koch[1], Ruda Alessi[1], Eduardo Macedo de Souza Tieppo[1], Rayanne Pereira Mendes[1], Renato Morais Bueno[1], Thainá Louise Rodrigues[1], Vitor Luiz Selva Pinto[1], Bruno Graziosi[1]

[1]Faculdade de Medicina do ABC, Santo André SP, Brazil.

Correspondence: Atilio Gomes Romani; Email: atilio_romani@hotmail.com.

Case presentation: Man, 26 years old, son of consanguineous parents with no family history of genetic or epileptic diseases. Asymptomatic until the age of 14, when his school performance declined. At the age of 18, he presented startle with myoclonic jerks, falls from his own height, difficulty walking and his first generalized seizure. Subsequently, despite the use of anticonvulsants, he progressed with generalized myoclonic tremors, dysarthria and decreased strength in the upper and lower limbs. Within a few years he was bedridden due to severe ataxia. The neurological examination showed: paratonia, sialorrhea, sardonic smile, presence of dystonic tremor of the four limbs, facial dystonia, moderate cognitive dysfunction (difficulty understanding), grade II general muscle strength. Computed tomography and magnetic resonance imaging were normal. The EEG: revealed bitemporal irritative activity independent of Sherriton. The genetic test was not available to define hypotheses, but neurological signs and clinical history corroborate the diagnosis of progressive myoclonic epilepsy. During hospitalization for pneumonia, the patient developed myoclonic status epilepticus and maintained the condition even after optimization of topiramate, valproic acid, levetiracetam, clobazam, cannabidiol and an infusion pump with ketamine and midazolam. Therefore, it was decided to introduce a ketogenic diet via a nasoenteral tube, showing an express response in the following days with the possibility of gradual withdrawal of sedatives and continuation of anticonvulsant drugs. **Discussion:** Progressive myoclonic epilepsy (PME) is a rare and heterogeneous group of epileptic syndromes characterized by myoclonus, instability, muscular instability, intellectual disability and epileptic seizures. PMEs are often caused by genetic changes, including genes such as PME1 and PME2. Clinically, PME is characterized by onset in childhood or adolescence with myoclonus and seizures, followed by progressive cognitive and motor decline. The diagnosis of PME requires a multidisciplinary approach, integrating clinical history, genetic and histological tests. Its treatment is based on symptoms control, but does not change the progression of the disease. The ketogenic diet (KD) is a diet rich in fat and low in carbohydrates, which induces a state of metabolic ketosis. Studies suggest that ketosis can stabilize neuronal excitability, reduce seizure frequency and, specifically for PME, decrease the severity of myoclonus. The relevance of KD in PME is particularly notable given the limitations of traditional anticonvulsants in controlling seizures in this population. Furthermore, KD may offer neuroprotective benefits by slowing the progression of neurological extension associated with PME. **Final comments:** In this report, we describe a case that was sucessful in controlling seizures using a ketogenic diet, which can be used as a basis for other studies and as a therapeutic tool for similar cases

https://doi.org/10.5327/CBN241012

Kleine-Levin syndrome after COVID-19: a clinical report of the use of clarithromycin during the crisis of hypersomnia

Aline Vieira Scarlatelli Lima Bardini[1], Silvia Rosa Neu[1], Maria Luiza Ataide Cardoso[1], Julia Pinter Del Castanhel[1], Victoria Pietsch[1], Gabriele Tartari de Souza[1]

[1]Universidade do Sul de Santa Catarina, Tubarão SC, Brazil.

Correspondence: Aline Vieira Scarlatelli Lima Bardini; Email: alinevieiralima@hotmail.com.

Case presentation: A 15-year-old male, with no personal or family history of neuropsychiatric disease or perinatal/developmental complications, has developed symptoms of hypersomnia, with episodes of severe daytime sleepiness, associated with hyperphagia and altered social behavior different from his typical pattern of sleep or humor. During the same period, he was diagnosed with hemolytic anemia, requiring hospitalization and frequent transfusions with human immunoglobulin. All these symptoms have been developed few days after a mild COVID-19 infection. Two months later, there were changes in the pattern of hypersomnia, characterized by long hours of sleep over a 7-day period, with episodes of partial awakening characterized by automatic behavior, along with hyperphagia and an altered mood. These episodes have occurred at least once a month, and a total of 3 episodes occurred before the neurological evaluation. Neurological examinations, blood exams and polysomnography were normal. The diagnose of Kleine Levin was done and treatment with lithium 300mg was prescribed. During the dose adjustment, the patient has showed a new episode of hypersomnia, and during the crisis the lithium was increased to 450mg and associated Clarithromycin 500mg, twice a daily, reducing the duration of episodes to 3 days with mild symptoms. After the symptoms improved, only lithium 450mg was maintained. There have been no new events since then. **Discussion:** Kleine-Levin syndrome is a rare condition of unknown origin. The clinical scenario is defined by intermittent and repetitive cycles of sleepiness associated with behavioral disturbances such as aggressiveness, mental confusion, and hypersexuality. Regarding its management, there are divergences in the literature, as its pathophysiological and etiological mechanisms are not yet clarified. Previous research has mentioned the use of lithium and carbamazepine due to the similarity of Kleine-Levin Syndrome with affective disorders related to Gabaergic receptors and monoaminergic neurotransmitters. Clarithromycin could be used during the crisis to reduce the episodes. Besides being an antimicrobial, there are reports of its action as a GABAa receptor antagonist, decreasing its inhibitory action on GABA. However, it crosses the blood-brain barrier only in situations of meningeal inflammation, which explains why the action in remitting the condition is temporary. **Final comments:** The pathophysiology, etiology, and treatment of Kleine-Levin Syndrome remain unknown. In the present case, the syndrome developed after the COVID-19 infection. The use of clarithromycin associated with lithium reduced the severity of symptoms and reduced hypersomnia episodes. This suggests that, in addition to Gabaergic and antimicrobial action, there may be a third mechanism that has not yet been clarified in the literature.

https://doi.org/10.5327/CBN241013

Knowledge of patients about the risk factors of ischemic stroke

Natalli Studnicka[1], Tatiana Pizzolotto Bruch[1], Amanda Honorato Matos[1], Nathalia Copetti Guzmán[1], Camila Pezente Dal Toe[1]

[1]Universidade do Extremo Sul Catarinense, Criciúma SC, Brazil.

Correspondence: Natalli Studnicka; Email: natalli.stu@gmail.com.

The study investigated the knowledge of attendees at a university outpatient clinic regarding the risk factors for ischemic stroke (IS). A total of 385 participants were interviewed, predominantly female (77.1%), aged between 18 and 84 years. Most had a monthly income between 2 and 4 minimum wages (49.4%) and had completed high school (20.8%). Approximately 69.4% reported previous contact with ischemic stroke victims. The risk factors most recognized by participants were systemic arterial hypertension, smoking, sedentary lifestyle, obesity, and chronic alcohol consumption, all identified by over 90% of respondents. Overall knowledge level was deemed moderate, especially among those with prior contact with IS victims. It was concluded that there is a significant gap in the understanding of ischemic stroke and there is a need to enhance public education on prevention and management of these risk factors., suggesting the need for measures to promote chronic disease control and adoption of healthy habits.

Laminopathy diagnosis: the importance of clinical correlation when considering a VUS mutation

Jéssica Cristina Silveira Damasceno[1], Laura Altomare Fonseca Campos[1], Júlia Lima Vilela[1], Marcelo Sobrinho Mendonça[1], Thiago Cardoso Vale[1]

[1]Hospital e Maternidade Therezinha de Jesus, Juiz de Fora MG, Brazil.

Correspondence: Jéssica Cristina Silveira Damasceno; Email: drajessicadamasceno@gmail.com.

Case presentation: A 13-year-old boy reported proximal weakness in the lower limbs with a pelvic tilt gait that began at 4 years old, followed by proximal weakness in the upper limbs at 6 years old. His father died at the age of 45 due to complications of a suspected muscular dystrophy, but without a molecular test. Physical exam showed hypotrophy of the biceps and triceps brachii bilaterally and muscle tone preservation. Electroneuromyography of the 4 limbs showed normal motor and sensory nerve conductions. Lower limb myography was also normal and the patient did not tolerated the exam in the upper limbs due to pain. Duchenne muscular dystrophy (DMD) testing ruled out the presence of deletions/duplications in the dystrophin gene, DMD locus XP, associated with Duchenne/Becker muscular dystrophy. A broad DNA panel of neuromuscular diseases was then carried out, which revealed a mutation with 1 heterozygous copy of the lamin A/C (LMNA) gene, variant of uncertain significance (VUS), raising the diagnostic hypothesis of laminopathy. At the last consultation, he presented preserved global strength, bilateral humeral atrophy, shortening of the bilateral Achilles tendon with walking on tiptoe, and noted initial peroneal hypotrophy. **Discussion:** The patient had a negative genetic test for DMD, the main diagnostic hypothesis in boys with proximal weakness. Electrophysiological study came out within normal limits, excluding the diagnosis of motor neuron disease. It was necessary to expand the diagnostic work-up with a broad genetic panel that detected a VUS mutation in the LMNA gene, establishing the diagnostic hypothesis of laminopathy, due to the clinical presentation shown by the patient combined with the exclusion of other diagnoses. Laminopathies can present with an extensive phenotypic spectrum, the main ones being: Emery-Dreifuss muscular dystrophy (EDMD), limb-girdle muscular dystrophy (LGMD) with cardiac conduction disorders, dilated cardiomyopathy and lipodystrophies. In EDMD, weakness occurs with a humeroperoneal pattern with early tendon contractures, which may occur even before the weakness, in addition to cardiac conduction disorders in adulthood. The patient, despite not presenting any classic phenotype of laminopathies, presents significant and unequivocal humeral atrophy and incipient peroneal hypotrophy, characteristic of EDMD. **Final comments:** This case illustrates the importance of the correlation between clinical picture and molecular test. After extensive investigation of myopathies, including dystrophies, it became important to value the VUS mutation, since a clinical phenotypic correlation could be established with the evidenced genetic alteration.

https://doi.org/10.5327/CBN241015

Langerhans cell histiocytosis involving the corpus callosum and spinal cord in an elderly patient

Mateus Pinto Marchetti[1], Isabela Louise Weber[1], Lucas Shigueo Hiromoto[1], Pedro Arthur Possan[1], Leandra Schneider[1], Karina Carvalho Higa[1], Karen Luiza Ramos Socher[1], José Eduardo Thomaz[1], Johny Bard de Carvalho[1]

[1]Hospital Nossa Senhora das Graças, Curitiba PR, Brazil.

Correspondence: Mateus Pinto Marchetti; Email: mateus.marchetti@live.com.

Case presentation: APF, 74-year-old female, admitted for an investigation of a 3 month onset ataxic gait, progressing to abasia in 1 week, associated with mood changes. Initial assessment showed left upper limb ataxia, grade 3 lower limbs paraparesis, abasia, upper limbs hyperreflexia, lower limbs hyporreflexia, hypopalesthesia, tactile, termal and pain hypoesthesia up to L1 level in lower limbs, dysarthric, dysprosodic, with liquid dysphagia and neurogenic bladder. Neuroaxis magnetic resonance imaging (MRI) revealed altered signal in corpus callosum's splenium (15x11mm) and left posterior fornix branch (10x6mm), characterized by T1 hypointensity, FLAIR/T2 hypersignal, DWI and ADC hypersignal, and gadolinium contrast enhancement; nodular foci with contrast enhancement were seen in cervical spinal cord, dorsal spinal cord, and conus medullaris, associated with diffuse spinal cord enhancement and thickening of cauda equina roots. Cerebrospinal fluid analysis showed 144mg/dL proteins, 29/mm^3 leukocytes (90% lymphocytes, 10% macrophages), 7mg/dL glucose, 10.4mmol/L lactate, and normal immunophenotypic analysis. Solid and hematologic neoplasm investigations (bone marrow biopsy and immunophenotyping) were negative. During hospitalization, the patient showed increased lesions on magnetic resonance Imaging, progressing to lower limb plegia. Central nervous system pathological diagnosis was consistent with Langerhans cell histiocytosis (positive for Vimentin, S100, CD68, and CD99 markers). There was no response to pulse therapy, starting then, treatment with Trametinib and Dabrafenib. **Discussion:** Langerhans Cell Histiocytosis is an inflammatory myeloid neoplasm. It commonly affects children aged 1 to 3 years, more frequently males. Its incidence in adults is not well defined. The disease predominantly involves bones (80%), and central nervous system involvement (LCH-CNS) is rare, with the hypothalamic-pituitary-adrenal axis being the most commonly infiltrated site. Clinical presentation of tumorous LCH-CNS depends on the location and type of central nervous system involvement. MRI is the imaging modality of choice for central nervous system evaluation, typically showing expansive lesions that are hypointense on T1, hyperintense on T2, and enhance post-contrast. Biopsy is necessary for diagnosis confirmation, revealing clonal neoplastic proliferation with CD1a, CD207, and S100 expression. Another important diagnostic marker is the BRAFV600E mutation, seen in 25 to 60% of patients. Prognosis depends on the extent of involvement and is worse if located in the central nervous system. **Final comments:** Faced with an extremely rare case of Langerhans Cell Histiocytosis, both due to the location of lesions and the patient's age and sex, this prompts us to consider this disease in the differential diagnosis of expansive central nervous system lesions, aiming for better prognosis through early diagnosis and treatment.

Case presentation: A 57-year-old patient with a history of recurrent pruritic vulvar lesions spanning 14 years presented initially with physical examination findings of friable erythematous-papular lesions in the vulvar and perineal regions. Infectious screening was negative. A biopsy of the lesion revealed Langerhans cell histiocytosis, confirmed by immunohistochemistry with the following markers: positive for S100 and CD1A, and negative for CD68. Treatment commenced with topical therapy, coupled with regular monitoring for systemic involvement. Neurological evaluation was prompted by the patient's recent onset of episodes involving brief behavioral arrests over the past year. Despite a comprehensive neurological examination yielding no abnormalities, an EEG demonstrated discharges in the left temporal region. Subsequent MRI of the brain identified expansive nodular formations with multilobular enhancement along the tentorium. Additionally, a nodular subcortical expansive lesion with paramagnetic contrast enhancement was noted in the right parietal lobe, indicating potential central nervous system involvement from the underlying disease. Furthermore, radiographic findings revealed ground-glass changes in the bony walls of the paranasal sinuses, suggesting concurrent bone involvement. Given the extensive systemic manifestations, the hematology team opted to initiate chemotherapy with cytarabine and dexamethasone. Initial treatment for focal epilepsy with carbamazepine proved ineffective, leading to a switch to levetiracetam. Upon reaching a daily dosage of 1500 mg, the patient experienced no further episodes of focal dyscognitive seizures. **Discussion:** Histiocytic neoplasms are uncommon, affecting approximately 5 individuals per million population.Central nervous system (CNS) involvement in Langerhans Cell Histiocytosis poses a significant challenge in clinical management. Pituitary lesions are prevalent, affecting up to half of LCH patients, often resulting in endocrinopathies, whereas dural lesions are less frequent (5% of cases). The presence of parenchymal lesions, as observed in our case with a subcortical lesion in the right parietal lobe, is even rarer but may indicate a more severe prognosis. The diagnosis of CNS involvement, indicated by pachymeningitis and parenchymal lesion, along with the visualization of skull bone lesions, prompted chemotherapy initiation, reflecting disease progression to a multisystemic form. This case highlights the critical importance of early recognition and treatment of neurological manifestations in LCH to enhance clinical outcomes and mitigate associated mortality. **Final comments:** Central nervous system involvement in LCH is rare; however, it can present with various clinical manifestations, many of which impact patients' quality of life and lead to a worse prognosis for the disease. Therefore, early recognition is crucial so that treatment can be effective in improving patient outcomes.

Late onset ataxia: Gerstmann-Straussler-Scheinker disease a diagnosis to consider

Verena Miranda de Souza[1], Alberto Rolim Muro Martinez[1], Tania Aparecida Marchiori de Oliveira Cardoso[1], Marcondes Cavalcante França Junior[1], Mayko Nascimento Merscher[1], Rafael Saliba Helmer[1], Maria Paula Oiticica de Jesus[1], Kaio Cezar Ferreira[1]

Correspondence: Verena Miranda de Souza; Email: vemirandasouza@gmail.com.

Case presentation: A 46-year-old previously healthy woman presented with a 4-year history of a subacute onset, but progressive, loss of balance and gait instability with frequent falls. Two years after the symptoms onset, she experienced, also in a progressive manner, dysphagia and dysarthria, along with a hearing loss. Neurological examination disclose scanning speech, dysarthria, square-wave-jerks, bidirectional nystagmus, in addition to vestibular hyporeflexia. There was also limb uncordination, more pronounced in the left segments and unstable gait requiring unilateral support. Motor strength and sensory perception were preserved. The Scale for the Assessment and Rating of Ataxia (SARA) score was 21.5. Complementary investigation was unremarkable and included cerebrospinal fluid annalisis, infectious, paraneoplastic, autoimmune and metabolic screening. Brain and spinal cord MRI revealed signs of mild cerebellar atrophy. A genetic test revealed a heterozygous mutation in the PRNP gene (p.Pro102Leu), associated with Gerstmann-Straussler-Scheinker disease (GSS), consistent with the late-onset progressive cerebellar ataxic syndrome. A follow-up cranial MRI conducted four years after disease onset showed evidence of decreased T2 signal in the dentate nucleus, striatum and midbrain. **Discussion:** GSS is a slowly progressive hereditary autosomal dominant neurodegenerative disease, caused by several different point mutations on chromosome 20. The most common mutation is at condon 102 of the prion protein gene (PRNP) leading to a substitution of proline by leucine. The prevalence between 1-10/100.000.000 and the clinical onset typically occurs in the fifth and sixth decades of life. Neurological signs and symptoms resulting from this mutation can be highly heterogeneous even between different family members. The clinical hallmark is a progressive cerebellar ataxia and/or parkinsonism accompanied by cognitive impairment. Dysarthria, abnormal eye movement, movement disorders (myoclonus and athetosis) pyramidal signs and symptoms can also be found in the disease course. The average illness duration is 40-50 months, which is longer than other prion diseases but relatively shorter than other genetic ataxias. Definite diagnosis requires genetic testing, however, brain MRI, RT-Quick and EEG findings can be helpful. Low signal intensity in the basal ganglia on T2-weighted MRI sequencies, similar to our case, is reported as a characteristic finding in GSS and is attributed to abnormally increased amounts of iron deposition. The loss in signal intensity on T2-w images due to iron deposition may mask the increase in signal intensity from spongiform degeneration, common in Creutzfeldt-Jakob disease, a different prion disease. **Final comments:** Late-onset ataxia is a challenging phenotype regarding its specific diagnosis. GSS, despite its rarity is a etiology to be considered specialy in those cases with familiar history and characteristic MRI findings

Late onset multiple acyl-coenzyme a dehydrogenase deficiency mimicking inflammatory myopathy: a case report

Catarina Dantas Corrêa[1], Delcio Caran Bertucci Filho[2], Claudia Kamoi Kay[1], Paulo Jose Lorenzoni[1], Renata Dal Prá Ducci[1], Paula Raquel Do Vale Pascoal Rodrigues[1], Otto Jesus Hernadez Fustes[1], Lineu Cesar Werneck[1], Rosana Herminia Scola[1]

[1]Universidade Federal do Paraná, Curitiba PR, Brazil. [2]Universidade Estadual de Ponta Grossa, Ponta Grossa, PR, Brazil.

Correspondence: Catarina Dantas Correa; Email: catarinadcorrea@gmail.com.

Case presentation: Male, 23 years old. Six-month onset of spontaneous myalgia, progressive strength loss and difficulty climbing stairs. Non-intentional weight loss of 17kg/5 months. Denied using anti-obesity medications (topiramate, metformin or triiodothyronine). No consanguinity. Used to practice football and had a history of obesity in childhood'. Maternal grandfather and four great uncles with Wilson's disease. Exam showed bilateral symmetric thigh atrophy, cervical muscles, upper and lower limbs hypotrophy associated with motor impairment: cervical 3+/5, upper limbs 4-/5 proximal and lower limbs 3+/5 proximal (MRC). Global arreflexia, except from bilateral bicipital hyporeflexia. No sensory abnormalities. Bilateral resting tremor. Myopathic gait. Blood test revealed elevated creatine phosphokinase (CK), aspartate amino transferase (SGOT), glutamic-pyruvic transaminase (SGPT) and serum B12 vitamin. Hemogram, erythrocyte sedimentation rate, C-reactive protein, renal and thyroid function, lactic acid, aldolase, ceruloplasmin and serum copper were normal. Abdominal ultrasound showed moderate hepatic steatosis. Normal thig MRI with gadolinium. Electroneuromyography with positive fibrillation and waves including paraspinal muscles, suggesting inflammatory myopathy. Multiple acyl-coenzyme A dehydrogenase deficiency (MADD) diagnosis was made after acylcarnitine dosage showed increased levels of C12, C14, C14-1 and Ca4-1/C4 and genetic b-fatty acid oxidation panel revealed a pathogenic mutation for ETFDH gene. The patient was treated with riboflavin, Q10 coenzyme, B12 vitamin, increased carbohydrate intake and reduced fat and protein intake with complete improvement of symptoms. **Discussion:** MADD is a rare, autosomal-recessive disorder caused by the lack or deficiency of the electron transport flavoprotein (ETF) or its dehydrogenase (ETFDH) in the mitochondrial flavoprotein chain. A mitochondrial flavoprotein deficiency leads to the accumulation of acylcarnitine of all chain lengths. The most common involved genes are ETFDH, ETFA or ETFB. There are three categories of MADD phenotypes: a neonatal onset form with congenital anomalies (type I) or without congenital anomalies (type II) and a mild and/or late-onset form (type III). Late-onset cases are common, with age presentation raging from adolescence to old age. Mainly manifestation is myalgia, symmetrical limb weakness with or without neck weakness and respiratory muscle weakness associated with increased CK. Our patient presented type II phenotype also affecting the liver. Due to its broad phenotypes, MADD can mimic inflammatory myopathy, Guillain Barré syndrome or myasthenia gravis. Electromyography typically reveals a myogenic pattern whereas a muscle biopsy usually shows lipidosis within type I muscle fibers. **Final comments:** MADD must be considered whenever there is acute or chronic muscle involvement associated with metabolic disorders.

Pompe's disease (PD) is a type of glycogen storage disease (GSD) that culminates in the accumulation of glycogen in the lysosome of various tissues, especially muscles.

Its transmission is autosomal recessive and located on chromosome 17. PD is classified into two forms: Infantile-Onset Pompe Disease (IOPD), considered the classic form, and a late-onset or non-classic form (Late-Onset Pompe Disease). , LOPD), which can occur in young or adult age with manifestations of skeletal myopathy and progressive respiratory and peripheral muscle weakness. This case reports a 32-year-old male patient who arrived at the neurology outpatient clinic in 2021 complaining of difficulty performing any activity that required physical strength. The condition began at the age of 26, with paresis in the upper limbs, which progressed over a period of 1 year with difficulty climbing stairs, getting out of bed and chairs and combing one's hair. He did not present dysphagia, choking or respiratory symptoms. The patient also reported the occurrence of an episode of low back pain diagnosed with a herniated disc in 2016, having undergone physiotherapy without improvement, which led to his initial referral to neurology outpatient clinics. On this occasion, ENMG and laboratory tests were requested, which diagnosed him as having muscular dystrophy of etiology to be clarified. It showed laboratory tests from September 2020, showing dosages of 2.8nmol/h/mL of acid alpha-glucosidase (GAA), alpha-galactosidase (GLA) of 4.66nmol/h/mL and CPK of 1,000U/L . At that time, corticosteroids were prescribed, in a decision motivated by the CPK dosage, and research for Pompe disease was indicated using a molecular panel examination to investigate muscular dystrophy. The panel was carried out in August 2021 and indicated a heterozygous pathogenic variant in the GAA gene. The following month, their enzymes were measured again, resulting in GAA of 1.40nmol/h/mL and GLA of 2.76nmol/h/mL, showing a reduction in GAA levels. With the diagnosis, the patient's clinical follow-up was based on the prescription of Enzyme Replacement Therapy (ERT) with the use of GAA (Myozyme). After starting to use the medication, a new dosage of GAA and GLA activities was carried out, which presented results, respectively, of 2.58mcmol/L/h and 4.07mcmol/L/h, showing an increase in their levels with appropriate replacement. enzymatic and, consequently, therapeutic efficacy. In many cases there is a delay between the first symptoms and diagnosis, which can last up to 10 years in the adult form. Unlike what occurs with muscular dystrophies of genetic origin, PD has a well-targeted treatment, which is ERT, which degrades accumulated glycogen, stopping the progression of the disease. Therefore, early diagnosis and therapy are crucial for a significant improvement in the quality of life of patients with PD.

Late onset Tay-Sachs disease in bBahia's countryside: a case report

Lukas Santos Freire[1], Emmanuel Santos Trindade[1], Érica Otoni Pereira Miranda[1], Giovana Andrade de Oliveira[1], Guilherme Rocha Cardoso[1], Priscila Santos Oliveira[1], Davi Tanajura Costa[1], Philip George Glass Andrade[1]

[1]Universidade Estadual do Sudoeste da Bahia, Vitória da Conquista BA, Brazil.

Correspondence: Érica Otoni Pereira Miranda; Email: ericaotoni15@gmail.com.

Case presentation: A male patient, 34 years old, son of consanguineous parents, reports that 5 years ago he began to suffer from progressive stiffness in the left lower limb and left upper limb, presenting difficulties with mobility and apprehension. The patient currently reports improvement in the symptoms of stiffness and weakness in the left hemibody with antiparkinsonian drugs (levodopa + benserazide 400/100mg/day and amantadine 300mg/day), but began to present similar symptoms on the right hemibody. He reports a sister and paternal uncle with similar symptoms, who are now deceased. On physical examination, there is evidence of Parkinsonian gait, resting tremor in the upper limbs, bradykinesia and significant asymmetric rigidity, more evident on the left, with preserved strength, sensitivity and coordination. Radiological examinations of the brain and spine did not provide any diagnostic information. In December 2022, mutation research was carried out on a gene panel for parkinsonism syndromes. This panel identified the missense variant c.533G>A (p.Arg178His) in heterozygosity in exon 5 of the HEXA gene, classified as pathogenic. A second pathogenic variant was not identified. Multiplex Ligation-dependent Probe Amplification (MLPA) and complete EXOMA sequencing also identified only the pathogenic variant described above. **Discussion:** Tay-Sachs disease is an autosomal recessive disorder caused by a deficiency of hexosaminidase A (HEXA), a lysosomal enzyme that normally degrades GM2 ganglioside. As a result, GM2 ganglioside accumulates in the lysosomes of nerve cells. Around 78 mutations in the HEXA gene have been described, which impair the activity of beta-hexosaminidase to varying degrees. Although the infantile form of the disease is the classic one, there are juvenile and adult presentations, due to residual HEXA activity, grouped together as Late Onset Tay Sachs Disease (LOTS). With regard to LOTS, its clinical presentation can be composed of cerebellar and neuromuscular symptoms, such as tremors, rigidity and spasticity, and psychiatric symptoms. Currently, LOTS management aims at relieving symptoms, which is why the case has shown a good response to antiparkinsonian drugs. **Final comments:** Family history, clinical presentation and identification of a pathogenic variant in the HEXA gene allow raising high suspicion of LOTS. However, as Tay-Sachs disease is autosomal recessive, requiring homozygosity or compound heterozygosity of pathogenic variants, we cannot be certain about this diagnosis at the moment, although it is very suggestive. It should be emphasized that LOTS should be considered in unusual cases of parkinsonism, although this adult form of the disease is even rarer than the others. Even without specific therapy, early diagnosis favors correct management, with antiparkinsonian drugs and psychiatric and genetic monitoring, with measurement of HEXA activity, which had not been performed, until this report, due to cost.

Background: Dementia is a progressive neurodegenerative disorder characterized by cognitive decline and its incidence in Brazil is 5 times higher in illiterates. Early life education is a well-established modifiable risk factor for dementia prevention. However, whether learning to read and write in adulthood contributes to brain health is still unknown. **Objective:** To elucidate the effects of a late-life literacy intervention on cognitive reserve and brain connectivity in illiterate adults. We conducted a longitudinal clinical trial within an adult-literacy program targeting low-educated adults which is called PROAME ("Programa de Alfabetização e Memória") **Methods:** First, 130 illiterate adults were screened at the basic education program for adults called EJA ("Educação de Jovens e Adultos"). After applying the exclusion criteria, 108 were recruited. Participants were divided into two groups: the control group (50 participants) attended the regular classes (literature, math, geography, history and sciences) and the intervention group (58 participants) attended part of the regular classes plus a specific training focused on learning how to read and write. Both groups attended their activities 4 days a week for 6 months. At the 6 month follow up visit, 77 participants successfully completed all required clinical assessments and interviews. Interviews were conducted to gather basic socio-demographic information, past and current medical history, use of tobacco, alcohol and illicit substances, physical activity levels and the presence of anxiety and depression. Participants also underwent a comprehensive cognitive assessment, which included executive functions assessment (digit span backwards, rapid number naming and phonemic verbal fluency), a functional brain MRI was performed to assess brain connectivity, especially the frontoparietal network, and a blood sample collection to measure plasma neurofilament levels. **Results:** We observed a significant increase in the episodic memory and executive functions in all participants, without a significant difference between the groups (control x intervention). When we adjusted the model for age, sex, reason for illiteracy and executive functions at baseline, we saw a significant improvement of executive functions in the intervention group. Factors that influenced in this result were attendance to classes combined with intensive literacy training, previous illiteracy related to rural areas residency, low executive performance at the baseline and lower levels of serum neurofilaments at baseline. In terms of brain connectivity, we saw that the intervention group had an increase in the frontal parietal and in the left hippocampal-temporal connectivity. **Conclusion:** Late life literacy training seems to improve executive functions, with and underlying rearrangement of the hippocampal and frontal connectivity.

Late-onset biotinidase deficiency mimicking adult leigh syndrome: case report

Kaliny Oliveira Peixoto[1], João Paulo Barile[1], Renan Brandão Rambaldi Cavalheiro[1], Patrícia Marques Mendes[1], Igor Braga Farias[1], Paulo de Lima Serrano[1], Wladimir Bocca Vieira de Rezende Pinto[1], Paulo Victor Sgobbi de Souza[1], Acary Souza Bulle Oliveira[1], Marco Antônio Trocolli Chieia[1]

[1]Universidade Federal de São Paulo, Escola Paulista de Medicina, São Paulo SP, Brazil.

Correspondence: Kaliny Oliveira Peixoto; Email: kalinyop355@gmail.com.

Case presentation: 20-year-old woman, she was born cesarean section, with prolonged expulsive period and circular of cord, birth weight 2500 grams, apgar 1/3/3, she presented with neonatal hypoglycemia, transient neonatal jaundice, probable perinatal sepsis, and infant hypotonia. She had delayed neuropsychomotor development. Since childhood, she had difficulty walking, dystonia in the lower limbs and later in the upper limbs, dysphagia and dysarthria. On examination, she presented with mild spastic hypertonia in the lower limbs superimposed on a dystonic component when walking; global hyperreflexia; cerebellar tests with dysmetria and dysdiadochokinesia in the upper limbs, with the presence of a dystonic component, predominantly on the left; and ataxic gait. The brain resonance showed global cortical atrophy, hypersignal in the pyramidal tracts bilaterally, focal signal changes in the bilateral thalamus, symmetrical, and in the posterior putamen bilaterally, spectroscopy without lactate peak, but with a small inversion of the creatinine/choline peaks in the basal ganglia. Muscle biopsy demonstrated selective atrophy of type II fibers and

subsarcolemmal mitochondrial proliferation. Organic acid profiles, electroencephalogram and optical fundoscopy disclosed no abnormalities. Laboratory screening showed pre-prandial lactate at the upper limit of normality; elevated post-prandial lactate; mild hyperammonemia; mild metabolic acidosis with a slight increase in anion gap; normal uric acid, creatine phosphokinase and aldolase. Gene panel disclosed the presence of the pathogenic variant c.1330G>C (p.Asp444His) in homozygosity in the BTD gene, confirming the diagnosis of biotinidase deficiency. The use of biotin 10 milligrams/day was started, with important improvement in fine motor coordination, in gait and reduction in the frequency of falls. **Discussion:** Late-onset biotinidase deficiency is an underdiagnosed inherited neurometabolic disorder, which can present with several neurological phenotypes, such as optic neuropathy, isolated optic atrophy, recurrent myelopathy, axonal polyneuropathy, cerebellar ataxia, sensorineural hearing loss and rarely mimicking neuroimaging features seen in Leigh syndrome. As biotinidase deficiency represents a metabolic disorder currently included in newborn screening programs, late-onset phenotypes may become probably rarely described in the following decades. Leigh syndrome is a complex neurogenetic group of metabolic disorders which can be caused by several distinct genetic variants, among which BTD pathogenic variants stand out. **Final comments:** The present report raises the diagnostic suspicion index for biotinidase deficiency, a potentially treatable condition, faced with Leigh Syndrome in adults. The timely treatment institution, consequently, provides an improvement in the patient's functionality.

Late-onset GM2 gangliosidosis due to mutations in GM2A gene mimicking spinal muscular atrophy type 3

Rodrigo de Holanda Mendonça[1], Juliana Gurgel Giannetti[2], Ronnyson Gativvol[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Departamento de Neurologia, São Paulo SP, Brazil. [2]Universidade Federal de Minas Gerais, Belo Horizonte MG, Brazil.

Correspondence: Rodrigo de Holanda Mendonça; Email: rodrigo.holanda@hc.fm.usp.br.

Non-5q spinal muscular atrophy (SMA) presents a diversity of genes described in the literature. Previously, GM2 gangliosidosis mimicking spinal muscular atrophy (related to mutations in the HEXA gene) was described. However, motor neuron disease related to mutations in the GM2A gene, which encodes a ganglioside activator protein, has not yet been described. Here, we describe a late-onset motor neuron disease phenotype mimicking SMA type 3 or 4, whose genetic investigation resulted in the finding of GM2A gene mutations. Case 1 is a male, 36 years old, history of parental consanguinity. He started progressive proximal muscular weakness in lower limbs at ten years old – weakness presented with slow progression over the years to the scapular girdle. Clinical evaluation at that time with 15 years old showed a motor neuron disease, being diagnosed as Kugelberg Welander disease (SMA type 3). At that time, neurological evaluation was remarkable for the presence of preserved tendon reflexes in 4 limbs. Weakness progressed slowly, and the patient lost his gait around the third decade of life. At the age of 35, he presented proximal and distal muscle atrophy, and tendon reflexes are now abolished, with exuberant polyminimyoclonus on examination. Cognitive is normal. Molecular investigation for deletions in the SMN1 gene ruled out that it was 5q SMA - it had 02 SMN1 copies and 00 SMN2 copies. Exome sequencing revealed a homozygous missense mutation at position c.428G> A (p.Gly143Glu) in the GM2A gene. Case 2 is a female, 43 years old, started muscle weakness of proximal predominance, exclusively affecting the lower limbs, around ten years ago and with electroneuromyography indicating a neurogenic process restricted to the quadriceps femoris and gastrocnemius muscles bilaterally. MRI of the thighs and legs showed exclusive involvement of the quadriceps femoris and gastrocnemius muscles, with a neurogenic pattern. Exome NGS showed two variants in compound heterozygosity (p.Gly143Glu and p.Gly166Arg) in the GM2A gene. Case 3 is a male, 40 years old, adult-onset muscle weakness of the lower limbs, mimicking SMA type 3, and investigation with NGS also showed two variants in the GM2A gene (p.Gly166Arg and p.Asp116His). The three cases presented here have in common a late-onset motor neuron disease mimicking SMA 3, with preferential involvement of the quadriceps and recessive mutations in the GM2A gene.

Late-onset Pompe's disease in children: case report and genetic particularities

Maria Luiza Vasconcelos Montenegro[1], Patrícia Trindade de Lucena[2], João Eudes Magalhães[2], Fabíola Lys de Medeiros[2]

[1]Universidade de Pernambuco, Recife PE, Brazil. [2]Hospital Universitário Oswaldo Cruz, Recife PE, Brazil.

Correspondence: Maria Luiza Vasconcelos Montenegro; Email: marialuizavasc534@gmail.com.

Case presentation: Male, 9 years old, started walking after 2 years of age, at the age of six, he progressively presented global muscle weakness and difficulty walking. Similar family history was denied. Neurological examination: mild facial biparesis, hypophonia, weak cough, global hypotonia, grade 4- proximal strength in the upper limbs and grade 3 in the lower limbs, grade 4+ distal strength in all limbs, strength deficit when standing up in the supine position, reflexes hypoactive and anserine gait. He also presented thoracic kyphosis, hypotrophy of the abdominal muscles, winged scapula, and slight atrophy of the shoulder and pelvic girdles. Electroneuromyography revealed myopathy. CPK dosage was 692 U/L. Complete sequencing of the GAA gene found the presence, in heterozygosity, of the variants described as chr17:80.118.209 CCA>C (2501_2502del];p.[?(;)Thr834Argfs*49]) and Chr17:80.104.542 T>G (NM_000152.5(GAA):c.[-32-13T>G]), both classified as pathogenic, in the GAA gene, associated with alpha-glucosidase deficiency (OMIM: 232300), autosomal recessive inheritance. The acid alpha-glucosidase dosage was 0.52 mcmol/L/h, with normal being greater than or equal to 2.10 mcmol/L/h. Transthoracic echocardiogram and spirometry were normal. Pompe Disease was diagnosed and he has been receiving an infusion of 12 vials containing 50mg of alpha-glucosidase, every 15 days for a year, undergoing motor physiotherapy. He has improved trunk strength, can stand up without supine support, strength grade of 4+ overall. Currently, he rides a bicycle. **Discussion:** The infantile form affects children in the first months of life, with cardiomyopathy, hypotonia, and rapidly progressive muscle weakness, and progresses to death within the first year of life. Late-onset disease can manifest between the first year and the sixth decade of life. Typically the late form does not present severe cardiomyopathy and disease progression is slower. Muscle weakness predominates in the proximal muscles with significant impairment of the lower limbs, resulting in impairment in carrying out daily activities, as seen in the reported case. The c.-32-13T>G variant is the most common GAA mutation associated with the childhood/adult phenotype. Almost 90% of patients affected by this phenotype carry this mutation on at least one allele. The chr17:80,118,209 CCA>C variant is quite rare, being present in heterozygosity in 2 of approximately 125 thousand individuals in the world population. Both pathogenic. **Final comments:** Pompe disease described is possibly caused by these two heterozygous variants in the GAA gene. The relevance of this case demonstrates that the disease started early, at least after 18 months, with a very slow progression and affecting the trunk muscles and that one year of enzyme replacement brought a lot of independence to this child. We also emphasize the Compound Heterozygous Mutations and rarity of the chr17:80.118.209 CCA>C variant, found in this patient.

Lateralized periodic discharges (LPDS) with identical periods

Taissa Ferrari Marinho[1], Luciana Rodrigues de Marchi[1], Luis Otavio Caboclo[1]

[1]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Taissa Ferrari Marinho; Email: taissaferrari@yahoo.com.br.

Case presentation: A 77-year old woman with high grade glioma on splenium of the corpus callosum was admitted in the hospital with cough, dyspnea, mental confusion and fever. After investigation, she started treatment for pneumocystosis. Five days after antibiotic theraphy initiation, she developed apathy, inattention, and presented an epileptic focal seizure characterized by behavioral arrest and right hand automatisms. She received 5mg IV diazepam and was taken to the intensive care unit. After two more clinical seizures, she received phenytoin. Patient evolved to consciousness impairment and started continuous electroencephalogram monitoring that showed diffuse disorganization of background activity and asymmetry, slower in the left hemisphere, infrequent triphasic waves, frequent epileptiform abnormality in the left temporal region, with a periodic pattern lateralized periodic discharges (LPDs) with identical periods of 0.5-0.6Hz, and eletrographic seizures on the left temporal region. Cerebral fluid showed herpes simples virus type 2. Patient had status epilepticus, received two more antiseizure medications and was sedated with propofol with seizure control. Although patient had seizure control, she persisted with severe sequelae of consciousness impairment. **Discussion:** LPDs are a frequent EEG pattern that have been described as an interictal, ictal and post ictal pattern, therefore the real significance of this pattern may be challenging in clinical practice. Recent studies showed that LPDs occur with a variety of etiologies and have the highest association with seizure risk, regardless of frequency, mainly when the Plus modifier is present. Our patient showed LPDs with identical periods; to the best of our knowledge, this pattern was not found in the literature before. LPDs with identical periods may have specific pathophysiology. Our patient had a high grade glioma that compressed the thalamus, a structure called the brain "pacemaker" by some authors, due to its relation to sleep spindles and periodic discharges. In addition, she had herpes encephalitis, which is a severe brain infection frequently associated with periodic pattern on EEG. Both diseases are of poor prognosis. Comatose patients after cardiac arrest can show malignant EEG patterns, that predict a poor outcome; burst-suppression with identical bursts, is one of these patterns. Would the identical periods seen in this case of LPDs be an indicative of poor prognosis, as seen with burst suppression with identical bursts in post anoxic patients? Would the identical repetition of morphology and time be of predictive value in patients with severe diffuse brain lesions? **Final comments:** LPDs is an EEG pattern frequently seen in critically ill patients, and show a high risk of seizure occurrence. LPDs with identical periods is a new specific pattern that could be associated with poor prognosis. Further studies will be needed to prove this hypothesis.

Left arm palsy and cerebellar ataxia revealing mycobacterium avium infection in a patient with HIV and systemic lupus erythematosus: a case report

Alex Araújo Fernandes[1], Matheus Alves da Silva[1], Matheus Luís Braga Munareto[1], Eduardo Mesquita de Souza[1], Rafael Bragança Rodrigues Matias[1], Ana Luísa Faria Donadon[1], Amanda Miranda de Mendonça[1], Christiane Monteiro de Siqueira Campos[1], João Antônio Gonçalves Garreta Prats[1], Alex Machado Baeta[1]

[1]Beneficência Portuguesa, São Paulo SP, Brazil.

Correspondence: Matheus Luís Braga Munareto; Email: matheusbragamunareto@gmail.com.

Case presentation: A 38-year-old woman presents with headache, myalgia, diarrhea and non-specific malaise for 3 days. She is diagnosed with systemic lupus erythematosus, using hydroxychloroquine, and 3 months ago she was diagnosed with HIV infection, undergoing treatment with dolutegravir, lamivudine and darunavir/ritonavir and currently with a viral load of 593 copies and CD4 of 248. Initially, the hypothesis of dengue was made, but the NS1 antigen test was negative 2 times. Stool culture and investigation of opportunistic agents in feces were requested, with negative results. Due persistence of headache and appearance of paresis of the left upper limb associated with appendicular and axial cerebellar ataxia, a head CT was made with a finding of focal hypoattenuation in the subcortical white matter of the right precentral gyrus. A MRI performed showed a cortico-subcortical nodular lesion in the right precentral gyrus with peripheral gadolinium enhancement and a central area with diffusion restriction associated with a double halo sign on T2. Also, there was nodular thickening of the pachymeningeal plane in the left temporo-occipital convexity, associated with infiltration of the adjacent bone plate with gadolinium impregnation and signs of diffusion restriction and leptomeningeal enhancement of the pial surface of the cerebellar vermis and in grooves between cortical gyri in the superior aspect of the cerebellum, associated with T2/FLAIR hyperintensity in the adjacent parenchyma. The cerebrospinal fluid analysis showed 6 cells, 69 proteins and 35 glucose, tests for microorganisms, including GeneXpert for tuberculosis, and antibodies were negative. Due to the characteristics of the precentral lesion on the MRI being suggestive of neurotoxoplasmosis, treatment with Sulfamethoxazole and Trimethoprim was chosen empirically, however, in radiological control after 15 days, a worsening of the lesions was observed with an increase in size and she had no clinical improvement. It was decided to perform a brain biopsy that showed a chronic granulomatous inflammatory process with central necrosis, and a positive culture for Mycobacterium avium. **Discussion:** Non tuberculous mycobacteria are rare human pathogens and usually infects immunocompromised hosts. These bacteria are divided in two main groups: Low-growing mycobacteria (Mycobacterium avium complex (MAC) and rapidly growing mycobacteria (Mycobacterium abscessus). The neurological manifestation of these diseases includes meningitis and/or parenchymal lesions. The diagnosis is usually made by tissue sampling. **Final comments:** With this case it was possible to observe a clinical and radiographic presentation of Mycobacteria avium infection, a rare central nervous system infection. This disease is usually difficult to diagnose and early diagnosis is essential for successful treatment.

Left oculomotor nerve paralysis after dengue infection: a rare neuroinfectious journey

Melissa dos Santos Matos[1], Daniel Mariani Favalessa[1], Guilherme Valiate Picoli[1], Emanuelly Victoria Andrade Fonseca[1], Ivo Gabriel Ribeiro Carvalho[1], Jovana Gobbi Marchesi Ciriaco[1]

[1]Universidade Federal do Espírito Santo, Vitória ES, Brazil.

Correspondence: Melissa dos Santos Matos; Email: melissa.matos@edu.ufes.br.

Case presentation: An 82-year-old female patient presented with vertical diplopia in the left eye and frontal headache at night. She came to the emergency room in February 2024. Initial examinations, including magnetic resonance imaging (MRI), ruled out stroke or aneurysm, and she was released. However, four days later, she was readmitted due to continuing symptoms. A new MRI revealed asymmetry of the left cavernous sinus with homogeneous contrast uptake. After further investigation, Tolosa-Hunt Syndrome was ruled out, based on the 2004 International Headache Society diagnostic criteria, and corticosteroid therapy was prescribed with methylprednisolone, 1 g/day, for three days. However, her condition progressed to complete left eyelid ptosis. Previous pathological history revealed an episode of dengue fever in January of the same year, confirmed by IgM. After careful analysis, she was diagnosed with left cranial III nerve palsy as a result of the dengue infection. **Discussion:** The dengue epidemic in Brazil is one of the main public health challenges today. Although the range of clinical signs of the disease is widely known, rare complications can occur, especially related to the DENV2 and DENV3 serotypes. In the case reported, the left oculomotor nerve palsy was manifested by vertical monocular diplopia, eyelid ptosis and frontal headache. The MRI findings, together with the exclusion of compressive lesions of the nerve and the absence of other infectious or inflammatory causes, establish the link between III nerve palsy and dengue infection. The most common causes of third cranial nerve palsy are ischemic, but they can also be secondary to viral infections. The pathophysiology of dengue-related neuritis is not yet clearly defined, although there are indications of immune-mediated mechanisms. The diagnosis should be made by excluding other etiologies, taking into account the history of viral infection. Treatment is controversial, generally opting for support, with the use of corticosteroids in refractory cases. Complete remission of symptoms can occur in up to 6 months. **Final comments:** Due to its long intracranial course, the oculomotor nerve is susceptible to injury at various anatomical points. Although it shows obvious clinical signs, III nerve palsy can have multiple causes, including neoplasia, demyelination, trauma and infections such as dengue fever, which often makes defining the etiological diagnosis a challenge. The growing incidence of neurological manifestations related to the immune-mediated reaction following dengue infection highlights the need to consider this etiology in cases of cranial nerve palsy - although they are still poorly described in the literature. Therefore, this case report highlights the importance of investigating infectious causes, especially in endemic areas such as Brazil, where dengue is prevalent, alerting us to the relevance of a broad and timely approach in similar cases.

https://doi.org/10.5327/CBN241028

Left temporal arteritis associated with ipsilateral amaurosis

Fábio Gonçalves[1], Felipe Leonardo Semensati[1], Letícia de Barros Dias[1], Marcelo Simplicio Carvalho[1], Nathalye Fernanda Pedroso Dircksen[1], Lorena Fernandes Kronbauer[1], Mônica Meneguette Silveira[1], Bárbara Okabaiasse Luizetti[1], Lucas de Oliveira Pinto Bertoldi[1], Damacio Ramon Kaimen Maciel[1]

[1]Irmandade da Santa Casa de Londrina, Londrina PR, Brazil.

Correspondence: Felipe Leonardo Semensati; Email: felipesemensati@hotmail.com.

Case presentation: T.A.B.S., 57, female, started with sudden pain in the left eye, ipsilateral amaurosis and hemicranial headache. Presented, as a previous comorbidity was hypertension, diabetes, dyslipidemia and glaucoma, using Losartan, Anlodipine, Metformin, Simvastatin and insulin. Attended at the Eye Hospital the following day with evaluation: Normal eye movement; Bilateral visual acuity 20/20; Bilateral intraocular pressure without changes. Fundus of eye: right eye without alterations and left with alteration of the foveal coloration. Referred for neurological evaluation, with hospitalization. At the entrance, at the neurological examination, an alteration was found in the ocular examination: visual turbidity in the left eye with predominance in the temporal field. Without changes on head CT and with changes in the cerebrospinal fluid in: Glucose 155; Proteínas 56; Lactate 3.3. 20 CmH20 manometry. In laboratory tests, increased VHS (56) and normal PCR (0.1). Following etiological investigation, skull resonance - which showed microangiopathy, and orbits resonance - was performed with hypersignal in the intra-orbital portion of the optic nerve on the left. Proposed diagnostic hypothesis of optic neuritis, instituted treatment with methylprednisolone 1 gram/day for 5 days. He maintained left amaurosis and ipsilateral hemicranial headache, being discharged with prednisone and outpatient follow-up. Following in etiological investigation, oligoclonal bands and anti-aquaporin 4 were performed, both without alterations. Left temporal artery biopsy was performed confirming temporal arteritis of giant cells. Maintained outpatient follow-up, evolved with improvement of headache. **Discussion:** Giant Cell Arteritis (ACG) is a granulomatous vasculitis that affects medium- and large-caliber arteries, particularly temporal arteries. Pathogenesis involves infiltration of the arterial wall by inflammatory cells, including T lymphocytes and macrophages, leading to inflammation and vascular damage. It manifests itself with systemic and specific symptoms. Systemic: fever, fatigue and weight loss and specific: headache, sensitivity in the scalp and lameness of the jaw. The most serious complication is sudden monocular amaurosis due to ischemia of the optic nerve. The diagnosis is clinical, supported by laboratory tests (VHS and PCR) that will often be elevated. Diagnostic confirmation can be obtained by biopsy of the temporal artery, which shows granulomatous inflammation. The recommended treatment is corticosteroid therapy to reduce inflammation and prevent ischemic complications. **Final comments:** Sudden monocular amaurosis, resulting from GCA, is an emergency that requires immediate diagnosis and treatment to preserve vision. Therefore, early recognition and aggressive treatment is essential to avoid complications and improve the prognosis of patients.

Leptomeningeal disease in genitourinary tract cancer manifesting as intracranial hypertension: case reports

Pedro Henrique de Oliveira Silveira[1], Verônica Guerra Matuella[1], Thales Pardini Fagundes[1]

[1]Fundação Pio XII, Hospital de Câncer de Barretos, Barretos SP, Brazil.

Correspondence: Thales Pardini Fagundes; Email: pardinithales@gmail.com.

Case presentation: We described two patients with genitourinary tract cancer complicated by leptomeningeal disease (LD). The first case involves a 61-year-old male with metastatic, castration-resistant prostate adenocarcinoma. After completing chemotherapy with docetaxel in December 2023, he presented in February 2024 with acute bifrontal headache, cognitive-behavioral fluctuation, and nausea. Examination revealed sixth cranial nerve paresis, psychomotor slowing, and disorientation. Brain MRI demonstrated post-gadolinium enhancement in the sulci of the right frontal and parietal regions, loss of signal suppression in post-contrast FLAIR sequence, and leptomeningeal enhancement in post-contrast T1 sequence, confirming LD. The second case is a thirty-four-year-old female with mixed squamous and adenocarcinoma cell cervical cancer. Post platinum-based chemotherapy in September and November 2023, she presented with right-sided hearing and visual loss, vertigo, and headache. Examination revealed a lateralized

Weber's test, papilledema, and optic nerve pallor. Brain MRI was inconclusive for LD, but cytology of three CSF samples showed neoplastic cells and elevated opening pressure of 60 cmH2O. Her lumbar puncture also revealed an elevated white cell count, suggestive of an inflammatory process secondary to the neoplastic involvement. The patient's management included corticosteroids to reduce intracranial pressure and alleviate symptoms, in addition to whole-brain radiotherapy. **Discussion:** LD diagnosis significantly impacts overall survival, which ranges from four to eight weeks. In genitourinary tract malignancies, LD is extremely rare. A retrospective review at MD Anderson Oncology Center revealed that among 41,830 prostate cancer patients from 1979 to 2011, only seven (0.016%) had LD. Similarly, in cervical cancer, only 0.03% of metastatic cases are associated with LD. Early recognition of neurological symptoms is vital for prompt diagnosis. Cytological CSF analysis and MRI with post-contrast enhancement are the most reliable diagnostic tools, with post-contrast FLAIR sequence being more sensitive than T1-weighted sequence. Effective supportive measures are essential due to the poor penetration of systemic therapy in the central nervous system and the rapid decline in performance status in these patients. **Final comments:** The diagnosis of LD is critical for prognostic and therapeutic decision-making, given the rapid deterioration in these patients. Current systemic antineoplastic therapies have limited central nervous system penetration. Clinical, diagnostic, and therapeutic discussions of LD in genitourinary cancers can provide valuable references for similar future cases, highlighting the need for more robust scientific evidence and effective treatments.

Levamisole-induced leukoencephalopathy

João Victor Cabral Correia Férrer[1], Lara Santos Machado[1], Luiz José Malta Gaia Ferreira Júnior[1], Luccas Almeida Andrade[1], Marianna Pinheiro Moraes de Moraes[1], Pedro Henrique Almeida Fraiman[1], Gabriel Pinheiro Martins de Almeida e Souza[1], Marcio Pinheiro Lima[1], José Luiz Pedroso[1], Orlando Graziani Povoas Barsottini[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: João Victor Cabral Correia Férrer; Email: jvccferrer@gmail.com.

Case presentation: A 62-year-old woman presented a 15-year-old history of progressive gait abnormality, with imbalance and frequent falls. After 5 years of disease progression, she required bilateral support to walk and, after 10 years, the patient was restricted to a wheelchair and exhibited cognitive dysfunction. Cocaine consumption was associated with de first clinical symptoms, and clinical stability was obtained since drug abstinence, which was approximately 2 years ago. It was noted that the patient's husband exhibited similar symptoms and also had a history of cocaine addiction. Physical examination evidenced axial and appendicular ataxia, spastic paraplegia and cognitive impairment primarily affecting executive functions. Brain magnetic resonance imaging (MRI) showed symmetrical leukoencephalopathy, including U-shaped fibers, with white matter cavitations, especially in periventricular regions, and thinning of the corpus callosum (FIGURE 1). Cerebrospinal fluid (CSF) evaluation was normal. Serum infectious, metabolic and autoimmune investigation was negative. LILE was diagnosed considering the clinical findings e its stability linked to drug abstinence, the presence of related person with similar exposure and symptoms, and the MRI typical abnormalities. **Discussion:** LILE predominantly affects females, between the 4th and 5th decades of life. Its progression is generally subacute and there are reports of recurrence of associated syndromes with re-exposure to levamisole, possibly due to a genetic predisposition. The three main clinical manifestations are muscle weakness, with or without hypertonia or hyperreflexia, language impairment and cognitive dysfunction, but cerebellar ataxia, altered level of consciousness and sphincter symptoms are also described. Brain MRI most commonly shows T1-hypointensity and T2/FLAIR-hyperintensity abnormalities in cerebral white matter characterized by asymmetric involvement in periventricular area, predominantly in the frontal region, with or without contrast enhancement related to blood-brain barrier disruption. CSF evaluation shows inflammatory pattern in 41% of cases, and elevated IgG index is the most frequent finding, followed by lymphomononuclear pleocytosis and hyperproteinorrachia, but oligoclonal bands were present in a minority of cases. Treatment consists in drug abstinence and pulse therapy with methylprednisolone and/or intravenous immunoglobulin and/or plasmapheresis. The prognosis is favorable in 96.7% of patients. **Final comments:** Thus, it is evident that both cases present clinical history and neuroimaging findings described in cases of LILE. However, the chronic course due to frequent re-exposure to this substance poses a diagnostic challenge. This atypical form of progression should be recognized and considered as a differential diagnosis in cases of chronic leukoencephalopathies when pertinent.

Light chain neurofilament in biofluids and its application as a potential biomarker in amyloidosis: preliminary findings

Larissa Bittencourt de Carvalho Chaffin[1], Ligia Rocha Andrade[1], Renan Amphilophio Fernandes[2], Soniza Vieira Alves-leon[2], Andreza Salvio Lemos[2], Izabela Jardim Rodrigues Pitta[3], Clarissa Neves Spitz[1], Robson Teixeira Vital[1], Salim Lázaro Balassiano[1], Marcia Maria Jardim Rodrigues[1]

Background: Peripheral neuropathies are a very common clinical condition and are associated with numerous cases of functional disability. There is a wide range of differential diagnoses associated with polyneuropathies, which can make it difficult to identify their etiology. The increasing emergence of treatments for these conditions demands the need to monitor the ideal therapeutic response. This monitoring often does not end with clinical and neurophysiological assessments and requires the use of biomarkers for neuronal damage, such as the measurement of neurofilament levels. **Objective:** To evaluate neurofilament light chain levels in biofluids as a biomarker of disease activity in patients with familial amyloid polyneuropathy associated with transthyretin. Investigate whether there is an increase in the dosage of neurofilaments in carriers of the transthyretin gene mutation, even if asymptomatic and after the first symptoms of the disease. **Methods:** Patients with a mutation in the transthyretin gene, whether symptomatic or asymptomatic, were selected. Patients who had comorbidities potentially causing peripheral neuropathies were excluded. All of them underwent electroneuromyography. Physical examination and clinical history data were used to classify patients on functional scales. Blood was collected in 4 milliliter samples and deposited in 2 to 3 tubes with ethylenediaminetetraacetic acid anticoagulant. The material is then centrifuged to separate plasma and serum. After centrifugation, the plasma was separated from the buffy coat and added to suitable tubes. Plasma, serum and buffy coat samples must be stored in a -80 °C freezer for later use. Plasma neurofilament concentration was measured by ultra-sensitive single molecule array technique. Preliminary **Results:** Of the 19 patients evaluated, only 2 had neurofilament levels comparable to healthy controls. Both were asymptomatic. All Coutinho stage 2 patients had plasma neurofilament levels about 4-fold higher at baseline relative to healthy controls. One of the patients showed a reduction of approximately 70% in plasma neurofilament levels 6 months after starting tafamidis, although he experienced clinical worsening. The use of biomarkers has been suggested as a means of stratifying patients and monitoring treatment. This is important because neurofilament is an integral component of the axonal structure of neurons, and the neuropathy observed with transthyretin amyloidosis is often characteristic of axonal injury. A 2021 publication showed that serum neurofilament dosages were four times lower in healthy patients than in patients diagnosed with transthyretin amyloidosis. **Conclusion:** The recent emergence of disease-modifying therapies demands the development of biomarkers so that treatment can be initiated earlier. This might prevent the development of disability by these individuals and greater success of therapy.

Limb girdle muscular dystrophy: autosomal recessive calpainopathy, case report

Laura Altomare Fonseca Campos[1], Jéssica Cristina Silveira Damasceno[1], Marcelo Sobrinho Mendonça[1], Thiago Cardoso Vale[1]

[1]Hospital e Maternidade Therezinha de Jesus, Juiz de Fora MG, Brazil.

Correspondence: Laura Altomare Fonseca Campos; Email: lauraaltomare8@gmail.com.

Case presentation: A 45-year-old previously healthy male patient, was evaluated with a history of mainly proximal weakness in the lower limbs with onset around the age of twelve with progressive worsening until the age of twenty-five, when he became dependent on the use of a wheelchair. He later developed proximal weakness in his upper limbs. There was no report of a similar family history or consanguinity. Physical examination showed proximal flaccid tetraparesis, predominant in the lower limbs, accompanied by global hypotonia with proximal atrophy in all four limbs. Electroneuromyography (ENMG) was compatible with myopathy in axial muscles, proximal upper and lower limbs, corroborating the diagnostic hypothesis of limb-girdle muscular dystrophy. A broad DNA panel was carried out and revealed a pathogenic mutation in homozygosity in the gene calpain 3 (CAPN3). This gene is responsible for the autosomal recessive limb girdle muscular dystrophy type 1 (LGMDR1). Magnetic resonance imaging (MRI) of the left hip, showed marked fatty degeneration of the muscle bellies of the pelvic girdle, proximal thigh and lower abdominal wall. Laboratory tests showed an increase in muscle enzymes. **Discussion:** Autosomal recessive calpainopathies are caused by pathogenic mutations in the CAPN3 gene, a protease involved in the cytoskeleton of muscles, and are the most prevalent subtype of limb girdle muscular dystrophy. It usually manifests in childhood, with variable phenotypes, from asymptomatic to those with proximal muscle weakness in the pelvic and scapular girdles, contractures and gait disorders. Patients are cognitively normal in most cases and progress from childhood with weakness, muscle atrophy, slow and progressive changes in gait, to loss of ambulation. Although the facial, cardiac and pulmonary muscles are generally spared in autosomal recessive calpainopathy, cardiac and pulmonary involvement can occur in girdle dystrophies, so it is necessary to carry out cardiological tests to screen for cardiomyopathies, abnormalities in the cardiac conduction system and ventilatory disorders. **Final comments:** It is important to make a differential diagnosis with other causes of proximal muscle weakness, in order to carry out the correct approach, screening tests for possible complications in the natural history of the disease, laboratory alterations, as well as appropriate rehabilitation and genetic counseling.

https://doi.org/10.5327/CBN241033

Limb levitation and alien limb as a rare initial manifestation of high grade glioma (glioblastoma multiforme)

Julyana Leoni do Prado[1], Mariana de Oliveira Trintinalha[1], Felipe Cardoso Garcia[1], Carlos Alberto Mattozo[1], Marina Farah[1]

[1]Pontifícia Universidade Católica do Paraná, Hospital Universitário Cajuru, Curitiba PR, Brazil.

Correspondence: Julyana Leoni Prado; Email: julyana.leoni@gmail.com.

Case presentation: Female patient, 61 years old, right-handed, treated on an outpatient basis complaining of weakness in the left hand and episodes of involuntary movements and a sensation of lack of control over the left upper limb. The patient describes that those movements interfere with daily activities, such as eating and in her job as a cook, especially performing unintentional activities, such as handling food while eating. There is still a feeling of weakness dropping objects. The patient had history of breast cancer treated with left breast quadrantopsy, radiotherapy and tamoxifen and had family history of neoplasia, 2 cousins of maternal origin diagnosed with neoplasia of the central nervous system. Neurological examination: grade IV left upper limb strength with distal predominance, ideomotor apraxia and slow elevation of the left upper limb triggered by tendon percussion and tactile stimulation, interrupted with interference from the examiner. Investigation with Skull Magnetic Resonance Imaging showed a lesion with mass effect on the right parietal lobe and signs of intracranial hypertension. She underwent resection and biopsy, confirming grade IV Glioblastoma multiforme (high-grade). After surgery, she obtained complete resolution of involuntary movements and, at that moment, grade IV left hemiparesis. Radiotherapy and adjuvant chemotherapy was performed. Patient remains under follow-up. **Discussion:** High-grade gliomas correspond, on average, to 2% of all gliomas. Peak incidence: 65 to 74 years. There is a slight predilection for males, with a ratio of 1.5 men to 1 woman. They may have different clinical presentations depending on topography and volume. Larger ones can develop intracranial hypertension. Seizures and focal neurological deficits are common presentations at diagnosis. One reported patient presented with atypical limb levitation and hand syndrome, which are more frequent in neurodegenerative diseases such as Corticobasal Degeneration (CBD). Alien hand syndrome can be divided into anterior, present in lesions of the frontal lobe, manifested by difficulty in holding objects, or in callous lesions, in which the affected limb makes conflicting movements in relation to the unaffected one. And into posterior syndrome, generally located in the parietal lobe, that presents with less complex movements of the affected limb (levitation, for example); this last variant was manifested by the patient described. Standard treatment for glioblastoma includes resection of the largest tumor margin, followed by radiotherapy and chemotherapy with Temozolomide (TMZ), a 5-year survival rate of 7.2%. In the case described, the patient relapsed after 4 months. **Final comments:** We describe a case of Glioblastoma Multiforme with an atypical manifestation of limb levitation, an unusual finding as a manifestation of significant neoplasms, highlighting the importance of investigating other non-degenerative causes in such presentations.

Limb-girdle muscular dystrophy TRAPPC11 related (LGMDR18) and central nervous system involvement

Diego Silva Figueiredo[1], Nadson Bruno Serra Santos[1], Alexandre Motta Mece[1], Aldrin Pedroza Martins[1], Izadora Vieira Bolzani Lopes Lima[1], Marcondes Cavalcante França Junior[1], Alberto Rolim Muro Martinez[1], Anamarli Nucci[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Diego Silva Figueiredo; Email: ddiegofigueiredo@gmail.com.

Case presentation: A 22-year-old man was attend to our outpatient clinic at age of 14 due to myopathy without an etiological diagnosis. His parents are consanguineous (first cousins). The patient presented normal development, except for speech delay, which he improved with the help of speech therapy. Since age 3 when he began experiencing motor incoordination, with difficulty walking in a straight line and postural instability. Furthermore, he had some difficulty learning and memorizing at school. At 14-years -old, the patient denied weakness, but reported myalgia, especially in the lower limbs after long walks and sports. On physical examination, he presented MRC grade IV+ in proximal upper and lower limbs, mild global hypotonia, normoactive deep tendon reflexes, dysmetria on the index-nasal-index maneuver without worsening with eyes closed, bidirectional horizontal nystagmus, ataxic gait and choreoathetoid movements in the distal region of the upper limbs. Complementary exams: all basic biochemical exams were within normal limits, except for elevated CK, up to 1096, LDH 532, aldolase 24.2. Negative acanthocyte test. ENMG showed a myopathic pattern in proximal and distal muscles in the four limbs, without detection of fibrillations or positive waves. Muscle biopsy and brain MRI were normal. He remained with stable symptoms over the years, with a diagnosis of myopathy plus central nervous system involvement without a specific diagnosis. In 2021, na exome detected a biallelic pathogenic variant in the TRAPPC11 gene, c.1287+5G>A, colocar a proteína também, compatible with the diagnosis of LGMDR18 (p.Ala372_Ser429del) **Discussion:** This case report presents a patient with myopathy, cerebellar ataxia, hyperkinetic disorder and speech delay. Myopathic pattern is compatible with LGMD. An exome revealed a homozygous pathogenic TRAPPC11 gene mutation (c.1287+5G>A) similar the description by Bogershausen N et al, 2013, in Hutterites families. These authors emphasized the disease spectrum of LGMD (latter named LGMDR18) and myopathy with movement disorder and intellectual disability. Muscle biopsy and brain MRI may not show changes. There is no specific treatment for this condition. **Final comments:** To date, we are unaware of any Brazilian case report of LGMDR18. Increasing knowledge of the pathogenic variants in LGMD and myopathy "plus" enable the diagnosis of many patients previously under follow-up and without a defined etiology, as occurred in our patient.

Linfoproliferative malignancy recidive as a stroke mimics

Maria Luiza Levindo Coelho Martinis[1], Bárbara Luisa Coraspe Gonçalves[1], Luiz Guilherme Gerhardt Fernandes[1], Marina Brasileiro Cesar Leitão[1], Bárbara França Amorim[1], Osvaldo Pantoja de Oliveira[1], Ana Carolina Andorinho de Freitas Ferreira[1], Cristiane Borges Patroclo[1], Marcelo Cagy[1], Jamison Menezes de Souza[1]

[1]Hospital Federal dos Servidores do Estado, Rio de Janeiro RJ, Brazil.

Correspondence: Maria Luiza Levindo Coelho Martinis; Email: mlevindocoelho@gmail.com.

Case presentation: Male patient, 19 years old, woke up with paresthesia in the right upper limb. He went to the emergency room and a brain CT disclosed an extensive hypodense area in the left hemisphere. He received the diagnosis of ischemic stroke and was discharged. Then, he sought hospital for better comprehension about his condition. On neurological examination, the patient presented subjective paresthesia without objective sensory impairment, and there was only a slight pronator deviation on his right. His anamnesis included a prior history of T-type lymphoblastic leukemia supposedly cured when he was 15 years old. Therefore, the clinical radiological dissociation observed elicited the suspicion of leukemic recurrence, this time in the central nervous system (CNS). Lumbar puncture was performed, and the cerebrospinal fluid was analyzed by the hematologist who identified 12 cells (atypical lymphocytes and blasts), suggestive of hematological disease recurrence, in the CNS this time. Intratechal chemotherapy was started. **Discussion:** Stroke mimics (SM) are defined as acute onset of focal neurological symptoms, which later is diagnosed with a non-vascular origin. Based on review articles, up to one-third of stroke admissions can be labelled as mimics. They are likely a misdiagnosis for: peripheral vestibular dysfunction, toxic/metabolic disturbance, seizures, functional disorder and migraine. SM is associated with lower NIHSS and affect prevailingly younger female individuals. In a large database review, 15,595 patients were analyzed, and space-occupying lesion represented <5%. In parallel, only up to 5% of patients with intracranial tumors seem to develop sudden onset of neurological features. Gliomas, meningiomas, and metastases are the main tumors masquerading as acute stroke. The mechanisms underlying acute "tumor attacks" include acute intracranial pressure changes leading to reduction in cerebral blood flow, vascular steal phenomena and vascular compression with resultant infarction. Thrombolysis may be prescribed in more than 1/4 of the cases. Although this procedure has very few complications in most of the SM, in case of brain tumor, it an absolute contraindication. Moreover, ignoring the actual etiology delays the proper treatment of a severe condition. **Final comments:** The case is an example of stroke mimics caused by an infiltrative tumor lesion. In the present case, the low NIHSS and the striking clinical radiological dissociation was another red flag to interrogate another etiology for the acute deficit. The reported case highlights the importance of emergency doctors being aware of stroke mimics and their possible critical etiology.

https://doi.org/10.5327/CBN241036

Livedo reticularis as a dysautonomic manifestation in bulbar ischemia

Aline Paredes Cardoso Fukuda[1], Bernardo Leite Ponde da Luz[1], Jacy Bezerra Parmera[1], Luiz Roberto Comerlattu[1], Fernando Freua[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Aline Paredes Cardoso Fukuda; Email: alineparedesc@gmail.com.

Case presentation: A 46-year-old female patient presented with acute and non-limiting onset of headache, vertigo, and tetraparesthesia. On the following day, she awakened with altered speech and right side weakness. She was admitted to the emergency unit and soon after progressed into hypoxia leading to cardiac arrest that was assisted until return to sinus rhythm. Upon evaluation, the patient presented with high blood pressure (206x114mmHg). She was alert, responsive to orders and able to reply non-verbally to simple questions. She had right-side hemiplegia and hypoesthesia, bilateral upper limb ataxia with prominent dysmetria, left-side Horner syndrome, nystagmus with a rapid phase to the left and worsening in right side gaze, and, skew deviation with hypotropic left eye. Facial sensitivity unimpaired and evaluation of bulbar nerves was hindered due to intubation. Notably, the patient presented with left-side livedo reticularis, strictly respecting the midline and sparring the right side. Initially, extubation was possible, however, hours later, she progressed with rapid respiratory failure and returned to ventilatory support. She persisted with

fluctuating vital controls and dysautonomia throughout the following days culminating in refractory shock and death. In investigation, cervical angiography revealed a left vertebral artery occlusion, and, MRI was compatible with ischemia in the left medulla, concordant with a Dejerine- Roussey syndrome. These findings were later confirmed in necropsy results. **Discussion:** Bulbar infarcts are associated with autonomic dysfunction due to lesions in the vagus nucleus and solitary tract. These structures are pivotal in the relay between hypothalamic outputs affecting cardiovascular, respiratory and gastrointestinal reflexes. The ventrolateral and ventromedial medulla contain sympathoexcitatory neurons that intermediate blood pressure reflex control in response to internal stressors. Acute vascular lesions in such topography can culminate in increased sympathetic activity promoting neurogenic hypertension and loss of baroreceptor regulation. Livedo reticularis is a skin manifestation of impaired perfusion, and in this case, its distribution was congruent with the topography of the ischemic lesion. Dysautonomic manifestations in midbrain infarcts are typically perceived as altered vital signs, however, this case shows how such manifestations can also affect other systems. **Final comments:** Autonomic dysfunction is an important manifestation of midbrain ischemic lesions and may lead to catastrophic outcomes. Patients with such pathology benefit from intensive monitoring and immediate interventions to stabilize vital controls. It is important to recognize that autonomic dysfunction may have an atypical clinical presentation in other organ systems, including the skin.

Background: Johannes Evangelist Purkinje was a remarkable Czech scientist who made discoveries concerning the structure and function of the eye, brain and heart which gave him countless eponyms. Beside biological science, Purkinje translated poetry from German, Russian and Polish to Czech and was an active Czech patriot. **Objective:** Brief review of Purkinje life and accomplishments in honor of his 150 th death anniversary. **Methods:** Based on literature research performed at PubMed. **Results:** On December 17, 1787, Purkinje was born in Libochovice Castle, then Bohemia – Empire Austro-Hungarian (now Czech Republic). Since a young child, Purkinje highlighted himself by his wit and intelligence. Attended the Piarist order at the Stará Voda monastery (Moravia), not to became a priest but to acquire advancer education. He then moved to Prague where attended physical science courses at the Philosophical Institute of Universitas Carolo-Ferdinandea and after enrolled as a student at Medical Faculty of the University of Prague which culminated with his dissertation, Contributions to the Knowledge of Vision from the Subjective Point of View in 1818 Acted as an anatomy instructor at Prague Medical Faculty between 1819 and 1822 and, in 1823, was accepted as Professor of Physiology and Pathology at the Medical Faculty of the Royal Prussian University of Breslau. In November 1839, Purkinje founded the Wroclaw's Institute of Physiology, which was not solely dedicated to research but also to Czech and Polish culture. In 1850, back in Prague, accepted the nomination of Professor of Physiology at the Medical Faculty of Prague, where he graduated. Honored with the Imperial Austrian Order of Leopold in 1868, conferred for merit and moral integrity, Purkinje died a year later, on July 28, 1869, in Prague. Despite his primary focus not being on cardiology, one of Purkinje's discoveries was the identification of a specialized conduction pathway in the heart known as Purkinje fibers. These fibers are now recognized as cardiomyocytes specialized in conducting electrical signals from the His bundle to the contractile ventricular myocytes. Among the many eponyms attributed to the Czech physiologist, perhaps one of the most celebrated are the Purkinje cells: the largest neurons of the cerebellum. Purkinje and his group examined slices of sheep cerebellum fixed with alcohol in a series of experiments that would accurately describe each of the three layers of the cerebellar cortex. Through these experiments, attributed to the cerebellum the role of precision of motor movements. Beyond histological descriptions, Purkinje also dedicated himself to investigating the mechanisms of balance and vertigo, giving rise to Purkinje's law of vertigo. **Conclusion:** Throughout his brief 52 years of life, Purkinje left a legacy which goes beyond the medical field. The year of 2024 marks 155 years of his death, however his contributions remain relevant and alive.

Logopenic variant of primary progressive aphasia: case report

Francisco de Assis Pinto Cabral Júnior Rabello[1], Giovana Sena Veloso Stefani Moreira[2], Adriana Ruphael de Freitas[2]

[1]Universidade Federal de Juiz de Fora, Juiz de Fora MG, Brazil.
[2]Faculdade de Medicina de Barbacena, Barbacena MG, Brazil.

Correspondence: Francisco de Assis Pinto Cabral Júnior Rabello; Email: francisco.cabral.neuro@gmail.com.

Case presentation: A.C.F.S, male, 58 years old, already diagnosed with unspecified dementia and using memantine 10mg/day for the last 3 years. His wife reports that 7 years ago he began to have progressive difficulties for communication, with hesitancy in the middle of sentences, which caused social isolation. He started to writ wrong, which was an issue since he works as a hospital receptionist and filled out forms. At time, he also had difficulty recalling recent events. Falls, signs of parkinsonism, behavioral problems, hallucinations and delusions weren´t present in the symptoms. In the first evaluation patient was completely dependent for daily activities, global cognition was moderately affected (CDR 2.0), despite the somatic neurological exam was normal. Neuropsychological evaluation exhibited marked difficulties in repeating verbal sentences, comprehension of long phrases and errors in writing and reading irregular words. Cerebrospinal analysis was normal, except for mild protein elevation (65mg/dl). Search for presenilin mutation (PSEN 1 and 2) was negative and the brain PET FDG-18F showed glycolytic hypometabolism in the posterior aspect of the cingulate gyrus as well as in the cortical topography of the bilateral temporal region, extending to the parahippocampal gyrus, inferior, middle and superior temporal gyri. Glycolytic hypometabolism was also present in the frontoparietal region, extending to the precuneus, more prominent on the left. **Discussion:** Logopenic variant of primary progressive aphasia (LV-PPA) is generally associated with atrophy of the posterosuperior temporal (perisylvian) and inferior parietal regions, which are areas involved in the auditory processing of speech and in the activation of phonological representations for language expression (phonological loop). The patient in this case presented hypometabolism in this region in the dominant hemisphere, which reinforces the diagnosis. Difficulty in lexical access during spontaneous speech results in hesitations and pauses in patients with LV-PPA. A more comprehensive assessment of language with specific tasks (comprehension of words and phrases; naming by visual confrontation; repetition of words and phrases with variable length; reading of regular and irregular words) may be necessary, as performance differs between the variants. Additionally, research into structural and molecular neuroimaging biomarkers may help, especially when demonstrating focal patterns of atrophy or hypometabolism. **Final comments:** The most common underlying neurodegenerative pathology in LV-PPA is Alzheimer's disease, with the language alteration attributed primarily to a deficit in the phonological component of working memory, which explains the difficulty in repeating sentences, the preservation of understanding of isolated words (which helps to differentiate from the semantic variant of PPA) and the relative preservation of fluency when compared to the non-fluent variant.

Background: Although neuropsychiatric symptoms are commonly reported in LONG-COVID syndrome, fewer studies evaluated their impact on work capacity. Here, we analyzed the persistence of symptoms of anxiety, depression, fatigue and sleepiness and the reduction in work capacity in a homogeneous group of workers with validated questionnaires. **Objective:** To investigate the longitudinal course of persistent neuropsychiatric symptoms and occupational vulnerability of post-survivors of COVID-19. **Methods:** We analyzed 173 individuals with confirmed COVID-19 (hospitalized (17.9%) and non-hospitalized (82.1%)) at two different times after acute infection (interval of 227 vs 614 days). The information was extracted from the database of a longitudinal study. Patients answered the "Chalder Fatigue Scale (CFQ)", "Epworth Sleepiness Scale (ESS)", "Hospital Anxiety and Depression Scale (HADS)" Patient Health Questionnaire-9 (PHQ9), and "Work Ability Index (WAI)". We used SPSS22 for statistical analysis with Chi-Square tests for analyses of proportions. **Results:** Our patients presented average age of 45 years (25 to 66 years), sex (59% female), education (43.9% complete undergraduate, 43.4% post-graduation, and 10.4% complete high school), function at work (68.2% contact with the public and 31.8% administrative work), reinfection (13.3%), vaccination (86.1%). With an average interval of 614 days between diagnosis and the second online interview, subjects SELF-reported several symptoms, including related fatigue (38.7% VS 45.1%; P=0.128), anxiety (41% VS 38.7%; P=0.594), depression (20.8% VS 18.5%; P=0.467), cognitive dysfunction (37% VS 42.2%; P=0.001); some reported to be asymptomatic, without post-COVID symptoms (3.5% VS 17.3%; P=0.614). However, the quantification of symptoms with validated questionnaires revealed unexpected changes. The comparison of symptoms between the two applications revealed an increase of excessive daytime somnolence (ESS) (58.4% to 75.1%; P=0.001), fatigue (CFQ) (55.5% to 79.9%; P<0.001), symptoms of anxiety (HADS) (6.4% to 35.5%; P<0.00) and symptoms of depression (PHQ9) (42.2% to 77.5%; P<0.00). The results reveal a reduction of WAI (23.4% to 63%; P<0.00). **Conclusion:** The results of this longitudinal study suggest that some subjects persist with neuropsychiatric symptoms almost two years after the acute infection, even those with mild disease. Surprisingly, this group of individuals presented worsening symptoms and working ability, which should raise the concern of potential long-term dysfunction in

post-COVID-19 individuals. As the responders volunteered for the study, we speculate that responders for the second interview were motivated by their persistent symptoms. However, despite this limitation, these results are valuable as we do not understand entirely the natural course of SARS-COV-2 infection. The study reveals a reduction in work capacity several months post-infection, suggesting economic impacts

Longitudinal analysis reveals the persistence of reduced work capacity and neuropsychiatric symptoms 25 months after infection in post-survivors

Gabriel Monteiro Salvador[1], Ana Paula Beppler Lazaro Lino[1], Fernando Cendes[1], Márcia Bandini[1], Clarissa Lin Yasuda[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Gabriel Monteiro Salvador; Email: gabrielsalvador1906@gmail.com.

Background: While numerous studies confirm that neuropsychiatric symptoms are prevalent in LONG-COVID syndrome, fewer have analyzed them longitudinally or investigated changes in work capacity after COVID-19. Here, we interviewed a group of survivors longitudinally to quantify neuropsychiatric symptoms and the reduction in work capacity in post-covid individuals with validated questionnaires. **Objective:** Our primary aim was to shed light on the course of persistent neuropsychiatric symptoms and the longitudinal variation in work capacity after COVID-19 disease. This research is crucial in understanding the long-term effects of the virus and its impact on individuals' ability to work. **Methods:** We analyzed longitudinal data from one study's database of 602 individuals with a confirmed diagnosis of SARS-COV-2 infection ((hospitalized (16.8%) and non-hospitalized (83.2%)) with an average of 216 days after acute infection (T1), followed by 173 individuals (hospitalized (17.9%) and non-hospitalized (82.1%)) with 614 days after the acute infection (T2). Finally, 46 subjects (hospitalized (21.7 %) and non-hospitalized (78.3%)) underwent the third application 774 days after the acute infection (T3). Participants completed the "Chalder Fatigue Scale (CFQ)", "Epworth Sleepiness Scale (ESS)", "Hospital Anxiety and Depression Scale (HADS)", Patient Health Questionnaire-9 (PHQ9), and "Work Ability Index (WAI)". Statistical analysis was conducted using SPSS22, employing Chi-Square tests to analyze proportions. **Results:** Our patients presented average age of 44 years (25 to 66 years), sex (53.5% female T1 vs 59% in T2 vs 58.7% in T3), education (43.9% complete undergraduate, 43.4% graduate, and 10.4% complete high school), reinfection (9.3% in T1 vs 13.3% in T2 vs 13% in T3), vaccination (83.4 % in T1 vs 86.1% in T2 vs 87% in T3). The comparison of symptoms between the three applications revealed persistent levels of excessive sleepiness (ESS) (70.4 % VS 75.1% VS 58.7%), fatigue (CFQ) (79.8% VS 79.9% VS 80.4%), symptoms of anxiety (HADS) (39.4% VS 35.5% VS 41.3%) and symptoms of depression (PHQ9) (30.9% VS 42.2% VS 28.3%). In addition, the results reveal the persistence of reduced WAI (64.8% VS 63% VS 63%). **Conclusion:** As expected in longitudinal studies, the number of responders reduced over time. Interestingly, the smaller groups of participants in T2 and T3 revealed long-term persistence of neuropsychiatric symptoms, which may impair daily life functioning. The elevated proportion of individuals with reduced work capacity raises the concern of a significant economic impact at both individual and collective levels. Given the uncertainties related to the natural course of SARS-COV-2 disease and LONG-COVID syndrome, these results raise the concern of potential long-term sequela associated with the new virus. More extensive studies are necessary to understand this course and provide data for prevention and specific treatments.

Spinal muscular atrophy (SMA) is an autosomal recessive disorder of lower motor neurons caused by biallelic loss-of-function SMN1 variants. SMA type 3 is a milder phenotype of the disease (patients are able to walk) and divided into types 3a (disease onset before 3 years old) and 3b (disease onset after 3 years old). The natural history of the more severe phenotypes (ie, SMA types 1 and 2) is well known, but much remains to be investigated regarding the clinical course of late-onset patients. Such knowledge gap represents a major limitation in the clinical management of these patients. This is particularly troublesome in the novel therapeutic landscape of SMA, where effective disease-modifying treatments are available. In this study, 17 healthy controls and 17 adult patients with SMA type 3 confirmed by genetic testing and clinical evaluation underwent spinal cord (SC) MRI. All subjects were scanned on a 3T Phillips Achieva Scanner using a 16-channel neurovascular coil for all SC images in two visits separated by one year. These were acquired in the axial-oblique plane with the center of the imaging volume positioned at the level of C2-3 intervertebral disc. To measure the cross-sectional (CSA) and the gray matter (GM) areas, we automatically segmented the cervical SC using a deep-learning algorithm. All MRI data were processed using the open-source software Spinal Cord Toolbox v4.0.1. The MFM scale was used to quantify disease severity. In the patient group, there were 12 men and 5 women with an average age of 32.1 years. A comparative analysis was conducted across-groups on the cross-sectional area of the spinal cord at the C3 level in patients during visits 1 and 2. No significant differences were observed neither in the comparison between patient groups across visits (p=0.89) nor in the comparison between patients and controls (p=0.20). Similarly, an evaluation of the GM area of the SC was performed in patients during visits 1 and 2, as well as in the controls. Once again, there was no significant change between visits both in motor scales and area, but there was a significant difference in the comparison between patients and controls (p<0.0001) In the combined evaluation with other variables, a strong correlation was found between the GM area and the values of the MFM scale (r=0.79, p=0.0002) Quantitative SC MRI emerges as promising neuroimaging biomarker in late-onset SMA. SC GM atrophy is the most promising candidate as it was found not only to distinguish patients and controls, but also to correlate with motor function in this disease.

Longitudinal evaluation of fatigue in adult patients with spinal muscular atrophy and the impact of treatment with disease-modifying drugs

Felipe Franco da Graça[1], Cristina Iwabe[1], Marcondes Cavalcante França Jr[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Felipe Franco da Graça; Email: felipefgraca@hotmail.com.

Fatigue is a prevalent symptom in Spinal Muscular Atrophy (SMA) and significantly affects the quality of life of individuals, particularly in performing repetitive daily activities. In adult patients, fatigue is a frequent complaint and a key factor that diminishes quality of life. This study aimed to evaluate fatigue in adult patients with SMA and correlate it with the use of disease-modifying drugs. We conducted a longitudinal study involving 25 adult patients (17 men and 8 women) diagnosed with 5q Spinal Muscular Atrophy confirmed by genetic testing. Each patient underwent an initial assessment using the Fatigue Severity Scale (FSS) to quantify fatigue levels, considering a score above 4 as indicative of fatigue. Additionally, the Hammersmith Functional Motor Scale Expanded (HFMSE) was used to assess motor function. Patients were reevaluated using the same scales after one year, with their treatment status documented at both visits. At the first visit, the mean FSS was 4.6, and at the second visit it was 4.9. As for HFMSE, the means were 20.8 and 20.3 at the first and second visits, respectively. We did not observe significant differences between the groups when all patients were evaluated together. Regarding treatment status, at the first visit, only 4 patients were using disease-modifying medications (all with nusinersen), while at the second visit, 9 patients were being treated (8 with nusinersen and 1 with risdiplam). Of the 5 patients who started medication between visits, 1 did not have significant fatigue previously. After treatment, 4 out of these 5 patients did not experience significant fatigue. The higher number of patients using disease-modifying medications at the second visit allowed comparisons between treated and untreated groups, showing that the proportion of patients with fatigue was significantly higher in the untreated group (81.2%) compared to the group that received specific therapy (33.3%) (p=0.03). No significant differences were observed in HFMSE among the same individuals. Our study population has a lower frequency of fatigue among treated patients compared to the untreated, although we did not observe significant differences in motor scales between the groups. Despite limitations due to the small number of patients, these findings support the clinical impression that treated adult patients experience a reduction in fatigue compared to untreated patients, providing an improvement in quality of life, regardless of changes in functional scales. Given that motor progression may be slow in adult patients, evaluating other factors such as fatigue may be relevant for clinical follow-up and assessment of therapeutic response.

Longitudinal T2-weighted MRI relaxometry in patients with temporal lobe epilepsy

Fernando Bruno de Aquino Cassol[1], Marina Koutsodontis Machado Alvim[1], Brunno Machado de Campos[1], Clarissa Lin Yasuda[1], Fernando Cendes[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Fernando Bruno de Aquino Cassol; Email: f242155@dac.unicamp.br.

Background: Temporal lobe epilepsy with hippocampal sclerosis (TLE-HS) is associated to higher rates of resistance to anti seizure medication (ASM). It is already known that these patients exhibit widespread white and gray matter structural abnormalities, such as volume reduction, extending beyond the temporal lobe and hippocampus. MRI T2-relaxometry can add information in the analysis of structural abnormalities in these patients, mainly in the hippocampus. **Objective:** Evaluate whether T2 relaxometry changes progress over time in patients with unilateral (L-HS and R-HS) and bilateral (Bil-HS) TLE-HS. **Methods:** Were included 131 TLE-HS patients from a tertiary center epilepsy outpatient clinics, divided into 3 groups, according to clinical data and HS visual analysis: 71 L-HS (42 women), 49 R-HS (31 women) and 11 Bil-HS (9 women). All patients had 2 MRIs with at least 1 year interval, including a high resolution 3D T1-weighted image

and a T2 multi-echo image (voxel= 0.45x0.45-0.45x0.9 mm³, gap= 3 mm, TE= 30, 60, 90, 120,150,180 ms, TR= 3300 ms and 36 coronal slices aligned to the hippocampi). The T2 maps were quantified using single exponential fit. The quantified maps were coregistered to the T1 WI, normalized to the MNI space and labeled using Desikan atlas. We chose the thalami, amygdalae and hippocampi and tested for longitudinal differences using paired t-test. **Results:** The groups had similar age at first MRI, the mean age of the patients was 46.21 (17.30 - 72.75). The mean interval between MRIs was 6.4 years (1.17 - 12.18) in L-HS group, 6.17 years (1.09 - 11.84) in R-HS and 7.88 years (6.34 -11.67) in Bil-HS group. In R-HS patients, we identified significant increase in their contralateral and ipsilateral thalamus (p=0.0001; p<0.0001) and hippocampus (p=0.0004; p<0.0001), with no significant changes in the ipsilateral and contralateral amygdala. In L-HS group, there was a significant increase signal in the contra and ipsilateral thalamus (p<0.0001; p<0.0001), hippocampus (p<0.0001; p<0.0001), ipsi (p=0.0002) and contralateral (p=0.0158) amygdala. Finally, in patients with bilateral hippocampal sclerosis, there were increases in the left (p=0.0180) and right hippocampus (p=0.0445), with no significant differences in their thalamus and amygdala, on both sides. **Conclusion:** There are changes over time in T2-signal in patients with TLE-HS in both hippocampi, regardless of whether it is unilateral or bilateral HS. In R-HS and L-HS patients, there were also changes in both thalami and in the L-HS group in both amygdalae. Whether these changes reflect gliosis or axonal or neuronal damage, remains to be confirmed.

Longitudinally extensive myelitis secondary to neuroschistosomiasis: case report

Stephania Neves Scapim[1], José Víctor Filho de Oliveira[1], Iasmim Portela Maifrede[1], Leopoldo Antônio Pires[1], Thiago Cardoso Vale[1]

[1]Universidade Federal de Juiz de Fora, Hospital Universitário, Juiz de Fora MG, Brazil.

Correspondence: Stephania Neves Scapim; Email: drastephanianeves@gmail.com.

Case presentation: A 65-year-old man with benign prostatic hyperplasia and essential tremor presents with a history of fatigue and unintentional weight loss in the past year. Subsequently, he developed hypoesthesia and progressive lower limb weakness, associated with urinary retention and fecal incontinence. After 6 months, he progressed to tetraparesis. He was diagnosed with transverse myelitis, confirmed by spinal cord magnetic resonance imaging (MRI) and cerebrospinal fluid (CSF). He underwent pulse therapy with methylprednisolone for 5 days with improvement in strength in his upper limbs. He was then referred to our service for further investigation. Physical examination revealed spastic crural paraparesis and tetrahyperreflexia with bilateral Babinski sign, signs of pyramidal release in upper limbs, bilateral hyperesthesia in T7-T12 dermatomes and hypoesthesia below T12 for all modalities, except for pain. Brain MRI revealed chronic intraparenchymal hematoma in the subcortical white matter of the right superior temporal gyrus. Cervical and thoracic MRI showed diffuse signs of spondyloarthrosis, with mild spinal canal stenosis highlighted at the levels C4-C5, C5-C6. In addition, it was noted an hyperintensity on T2/STIR compromising the central portion of the dorsal spinal cord from the level of D1 to the conus medullaris. Foci with faint enhancement by intravenous contrast were noted sporadically in the right lateral funiculus and central portion of the spinal cord at the level of D4, D6 to D7. CSF showed glucose 50 mg/dL, 27 cells (97% mononuclear), protein 133 mg/dL, with presence of oligoclonal bands, type 2 pattern. Anti-AQP4, ANCA-c and ANCA-p were negative. Screening tests for HIV, HTLV, syphilis, toxoplasmosis and hepatitis were also negative. Immunological test for schistosomiasis was positive in serum (1:128) and CSF (1:2), suggesting the hypothesis of longitudinally extensive transverse myelitis (LETM) due to neuroschistosomiasis (NE). Treatment with praziquantel and pulse therapy with methylprednisolone was performed, followed by prednisone. The patient showed complete improvement of symptoms in the upper limbs and partial improvement in the lower limbs. He continued to experience urinary retention and constipation. **Discussion:** We present a case of NE as the cause of spastic paraparesis with hypoesthesia below T12, and sphincter dysautonomic syndrome. NE is uncommon and can cause serious neurologic complications, involving the spinal cord and/or the brain. Patients with myelopathy may present with lower limb pain, lower motor dysfunction, bladder paralysis, and bowel dysfunction. **Final comments:** Differential etiologic diagnosis for LETM should include schistosomiasis, especially in endemic areas.

Longitudinally extensive transverse myelitis after hand-foot-and-mouth disease in an adult, immunocompetent patient: a case report

Víctor de Moraes Chagas[1], Bruno Henrique Carneiro Costa Filho[1], Luísa Couceiro de Albuquerque Macêdo[1], João Pedro Matos de Santana[1], Lucas de Andrade Alexandre[1], Mariana de Almeida Cruz Silva[2], Luziany Carvalho Araújo[3], Clélia Maria Ribeiro Franco[1], Álvaro José Porto Moreira[1], Eduardo Sousa de Melo[2]

[1]Universidade Federal de Pernambuco, Hospital das Clínicas, Serviço de Neurologia, Recife PE, Brazil. [2]Universidade Federal de Pernambuco, Centro de Ciências Médicas, Recife PE, Brazil. [3]Universidade Federal de Pernambuco, Hospital das Clínicas, Serviço de Radiologia, Recife PE, Brazil.

Correspondence: Mariana de Almeida Cruz Silva; Email: mariana.almeida20021@gmail.com.

Case presentation: A 46-year-old male patient was admitted to the Neurology infirmary with a history of acute urinary and fecal retention, symmetrical weakness in the legs and torso, and hypoesthesia below his chest, initiated 30 days prior. On admission, he had grade II symmetrical spastic paraparesis of the legs, brisk patellar and Achilles reflexes, bilateral Babinski sign; brisk arm reflexes, with no weakness; and urinary retention requiring indwelling urinary catheter. By the time of admission, axial weakness, hypoesthesia, and fecal retention had resolved. No prior similar symptoms, chronic illnesses, or substance use were reported. However, two weeks before these symptoms, he had malaise, muscle pains, low fever, hyporexia, and erythematous, pruritic rash on both hands. His 8-year-old son had presented similar lesions on his hands, feet, elbows, and around the lips, days before. Spine MRI showed bilateral T2-hyperintense lesions on grey matter from C3-T12. CSF analysis showed a high protein level (70 mg/dL) with normal cell count. PCR for myelitis-associated viruses, collected one month after onset, was negative. He was treated with methylprednisolone 1 g/day for 5 days, with improvement of symptoms. Six months after treatment, he had no sequelae, and a new spinal MRI was normal. **Discussion:** Hand-foot-and-mouth disease is usually benign, caused by enteroviruses, most commonly by Coxsackie A16, a well-established cause of aseptic meningitis, encephalitis, Guillain-Barré syndrome, and acute flaccid paraparesis; transverse myelitis is reported, but rare. Viral myelitis commonly causes only mild alterations on CSF analysis and spinal cord imaging, and clinical history is paramount to diagnosis. History must include recent travel to endemic areas, immune suppression, and associated symptoms. Our patient had not traveled recently, nor had a history of immune alterations. Skin rash, accompanying or preceding neurological symptoms, favors the possibility of enterovirus or herpesvirus infection. Negative viral DNA investigation on CSF can be explained either by the delayed time from symptom onset to sample collection; or by an immune-mediated lesion with no direct viral invasion to the nervous system. The absence of previous similar symptoms and normal follow-up MRI suggest monophasic acute myelitis, compatible with our hypothesis. Our patient had an excellent response to corticosteroid therapy, which was not seen in previously reported cases. **Final comments:** We present the case of an adult, immunocompetent patient who developed monophasic longitudinally extensive transverse myelitis after symptoms of hand-foot-and-mouth disease. Despite negative viral analysis of CSF, enterovirus is a highly likely etiology, considering associated symptoms and clinical history. Because of the very few cases reported, it is impossible to determine the optimal time and treatment course for similar cases.

Longitudinally extensive transverse myelitis as a manifestation of systemic lupus erythematosus

Paulo Victor Machado[1], Ana Paula G. Barankiewicz[1], Lucas R. Prim[1], Paola R. González[1], Lisseth F. V. Reyes[1], Maria Julia B. Rodrigues[1], Isabela Wandarti Ribas[1], Lucas Voigt Machado[1], Bruna Conti[1], Marcos Seefeld[1]

[1]Hospital Universitário Evangélico Mackenzie, Curitiba PR, Brazil.

Correspondence: Paulo Victor Santos Machado; Email: paulovictorsmachado@gmail.com.

Case presentation: Female patient, 29 years old, previously diagnosed with systemic lupus erythematosus (SLE), using hydroxychloroquine and mycophenolate mofetil, with a previous episode of transverse myelitis in 2022, at the time treated with methylprednisolone pulse therapy and 6 pulses of cyclophosphamide. Admitted to the service in 2023, with tetraparesis and urinary incontinence, in addition to sensory level at T1. Subjected to neuraxial MRI, longitudinally extensive myelitis was demonstrated, with the lesion extending from the medulla oblongata to the level of C6. Examination of the cerebrospinal fluid showed a slight increase in proteins and negative oligoclonal bands. Negative anti-aquaporin 4 antibody in serum. Pulse therapy with methylprednisolone 1g/day was started. The patient developed hypercapnic respiratory failure, requiring orotracheal intubation and transfer to the intensive care unit (ICU) on the 3rd day of hospitalization. Finished 5 days of treatment with corticosteroid pulse therapy, without improvement in muscle strength. The patient underwent plasmapheresis and developed septic shock with a pulmonary focus. Culture-guided antibiotics were started, plasmapheresis was suspended due to the infectious context, and pulse therapy with cyclophosphamide was chosen, with partial improvement in muscle strength. The patient underwent tracheostomy and developed a new septic shock with a pulmonary focus, refractory to clinical measures. **Discussion:** Systemic lupus erythematosus (SLE) can affect the central and peripheral nervous system. Occasionally, patients present spinal cord involvement through inflammatory activity. Transverse myelitis is a relatively rare manifestation of the disease, with an incidence of around 1-2% of patients with SLE. Magnetic resonance imaging (MRI) is the imaging modality of choice for investigating myelopathies. Lesions that involve three or more contiguous vertebral bodies are classified as longitudinally extensive. In a review of 63 cases of myelitis associated with SLE, 71.4% of patients manifested longitudinally extensive myelitis. The measurement of oligoclonal bands in CSF can help distinguish transverse myelitis related to multiple sclerosis. Likewise, it is necessary to measure anti-aquaporin 4 antibodies in the patient's serum, to exclude myelitis associated with neuromyelitis optica. The treatment of lupus myelitis derives directly from the treatment of SLE and idiopathic myelitis. Methylprednisolone and cyclophosphamide are commonly used as first line when there is serious and threatening target organ involvement. Plasmapheresis is an option in refractory cases. Other

options are represented by mycophenolate, rituximab, azathioprine and human immunoglobulin. **Final comments:** Cases of myelitis associated with lupus can occur regardless of the degree of activity of the underlying disease. Rapid recognition of the condition and early initiation of treatment are associated with better outcomes.

Long-term cardiac magnetic resonance imaging study in Friedreich's ataxia

Thiago Junqueira Ribeiro de Rezende[1], Alberto Rm Martinez[1], Mariana R de Brito[1], Renan Ff Nunes[1], Luis M Silva[1], Karen Ag Takazaki[1], Melina P Martins[1], Fernando Cendes[1], Michael Jerosch-Herold[2], Otávio R. Coelho-Filho[1]

Correspondence: Thiago Junqueira Ribeiro de Rezende; Email: thiago.jrezende@gmail.com.

Background: Friedreich's ataxia (FRDA) demands the identification of biomarkers crucial for clinical management and clinical trial planning. Despite heart failure being the primary cause of mortality in FRDA, there remains a lack of dependable cardiac biomarkers. While cardiac magnetic resonance imaging (cMRI) has emerged as a promising option, longitudinal cMRI data for the disease are limited. **Methods:** Initial cMRI scans were conducted on 18 healthy individuals and 42 FRDA patients, with 17 of the latter group receiving repeat cMRI scans after a 5-year interval. The study involved the measurement of left ventricle ejection fraction (LVEF), mass, and volumes, as well as the evaluation of late gadolinium enhancement (LGE), extracellular volume fraction (ECV), and intracellular water-lifetime (τic). Neurological deterioration was quantified using the FRDA rating scale (FARS). **Results:** Analysis of the data revealed that FRDA patients displayed preserved LVEF but increased left ventricle volumes, thickness, ECV, and τic in comparison to the control group. Nine out of 41 patients exhibited epicardial LGE. Furthermore, the left ventricle volumes showed correlation with FARS scores. Longitudinal assessment demonstrated no significant decline in LVEF; however, an increase in left ventricle diastolic volume and a decrease in the left ventricle volume/mass ratio were observed. Five additional patients displayed epicardial LGE after the 5-year follow-up. **Conclusion:** The cross-sectional analysis highlighted that FRDA patients maintain preserved LVEF but exhibit increased left ventricle volumes and thickness due to myocardial interstitium expansion and cardiomyocyte size enlargement. Noteworthy findings from the longitudinal follow-up suggest evolving heart damage and a transition from a hypertrophic cardiomyopathy phenotype to a dilated cardiomyopathy phenotype. In conclusion, cMRI has unveiled valuable insights into cardiac involvement in FRDA and could serve as a valuable biomarker for monitoring disease progression.

Background: Numerous observational trials have shown the use of deep brain stimulation on freezing of gait in patients with Parkinson's disease (PD). However, it remains unclear what is the long-term effect of this intervention. **Objective:** Therefore, we conducted a meta-analysis to assess the long-term effect of subthalamic nucleus deep brain stimulation (DBS) on freezing of gait in PD. **Methods:** We systematically searched PubMed, Embase and Web of Science for studies using subthalamic nucleus deep brain stimulation on freezing of gait in PD. Primary outcomes were Gait item Axial Symptoms items in the Unified Parkinson's Disease Rating Score (UPDRS), measured by mean and SD scores. For this single-arm meta-analysis a random effects model was used to calculate the pooled proportions with 95% confidence intervals. Statistical analysis was performed using the R program (version 4.3.2). Heterogeneity was assessed with I2 statistics. **Results:** Fifteen studies were included in this meta-analysis, comprising 407 patients with PD treated with subthalamic nucleus deep brain stimulation. Mean score on Gait item 29 on medication off DBS was 7.39 points (95%CI = -4.27-23.68; I2 = 97%), while mean score on Gait item 29 on medication with DBS was 7.05 (95%CI = -0.78-14.87; I2 = 96%). Combined Axial symptoms score, defined as the sum of the motor scores: item 18, 22 (rigidity of the neck) and items 27-30, revealed a mean score of 9.71 points (95%CI = -4.27-23.68; I2 = 97%) on medication off DBS, and 9.01 score on medication on DBS (95%CI = -1.02-19.04; I2 = 99%). **Conclusion:** In PD patients with freezing of gait symptoms, long-term subthalamic nucleus deep brain stimulation was associated with better scores of Gait and Axial Symptoms items in the Unified Parkinson's Disease Rating Score (UPDRS).

Long-term memory trajectories in seizure-free patients operated for hippocampal sclerosis

Roberta Gomes[1], Eduardo Leal-Conceição[1], Caroline Schiochet Verza[1], Wyllians Vendramini Borelli[1], Mirna Portuguez[1], William Alves Martins[1], Eliseu Paglioli[1], Andre Palmini[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Caroline Schiochet Verza; Email: carolinesverza@gmail.com.

Background: Antero-mesial TLE surgery is usually safe, although the possibility of significant decline in memory function should be considered. Several predictors have been advanced, the most relevant being the pre-resection structural and functional status of these structures as verified by MRI and neuropsychological evaluation. In general, the more preserved the structure and /or the function, the higher the risks for post-operative memory deficits. However, post-operative memory is usually assessed only in the first few years and function in thevery long-term is seldom addressed. Furthermore, there is a tendency to group patients with TLE due to distinct pathologies and achieving variable post-operative seizure outcome **Objective:** To study memory trajectories over the years in patients with temporal lobe epilepsy and unilateral hippocampal sclerosis (TLE/HS) seizure free since surgery. **Methods:** Memory tests were applied before (T1), 1 to 4 years (T2) and 10 to 15 years after operation (T3) in 54 patients with TLE and pathology-verified HS (34 left), seizure free since surgery. Logistic regression evaluated variables correlated with memory function at each point in time. A Reliable Change Index (RCI) was performed to identifty changes at individual measures. **Results:** Forty-four to 52% of patients with left HS had normal either preoperative verbal learning (VL) or memory (VM) and this associated with worsening at T2 and T3 (p=0.029 and 0.045 for VL; p<0.015 and p<0.001 for VM, respectively). Between 50 and 70% of those with left HS and normal preoperative VM or VL sustained function at T2, although the majority worsened in the long term (T3). Around 30% of patients with left HS improved function in VM or VL at T2, but most worsened at T3. In contrast, 15% of patients reversed from dysfunctional to normal performance in VL between T2 and T3. Visual memory (VisM) following non-dominant surgery also worsened at T3 for patients who improved or sustained normal performance between T1 and T2. Worsening in VM or VL correlated with normal preoperative function, younger age, low schooling, surgery in the dominant side and nonselective surgical technique. Around 91% of the operated patients showed no reliable change in memory tests across T1-T2, T2-T3 and T1-T3. **Conclusion:** Memory preservation or improvement in the first few post-operative years is usually not sustained in the long term, suggesting that disease progression surpasses plasticity over the years.

Correspondence: Ana Carolina Gomes; Email: gomesac90@gmail.com.

Background: The long-term neurological consequences of cumulative head trauma were initially recognized in professional boxers. Over many years, these athletes are on the receiving end of thousands of blows to the head of varying intensity, in sparring and matches. The initial description of what is now known as chronic traumatic encephalopathy (CTE) was reported in boxers in 1928. The clinical features of CTE include various symptoms affecting the pyramidal and extrapyramidal systems, which manifest most often as disturbed gait and coordination, slurred speech and tremors, as well as cerebral dysfunction causing cognitive impairments and neurobehavioural disturbances. **Objective:** To evaluate the sensitivity and specificity of neuroclinical, neuropsychological and electroencephalogram (EEG) findings in the diagnosis of chronic traumatic encephalopathy in a cohort of retired boxers. **Methods:** A prospective observational study was conducted. Eigth retired boxers and 14 controls were evaluated and submitted to neurological evaluation, neuropsychology evaluation and EEG. **Results:** In the retired boxers group the average age was 64.3 years (55.7 in the CG), average of 9.8 schooling years (13.7 in the CG). The average results in MMSE was 22.8 (29 in the CG), the average verbal fluency for letter F was 11.3 (13,5 in the CG), the average digit span in backwards was 2.5 (3.8 in the CG), the average verbal fluency for animals was 13.8 (24 in the CG), the average clock-drawing test was 8.6 (9 in the CG) and the average FAB (Frontal Assessment Battery) was 13.3 (17.5 in the CG). Visual EEG analysis showed a predominance of posterior alpha activity with 9.5 Hz average in the boxer participants and 11 Hz in the control group (CG). The analysis with low resolution electromagnetic tomography (LORETA) showed that 5 boxers had hippocampal asymmetry (3 had less activity

in the right hippocampus and 2 had less activity in the left hippocampus). Of the 9 boxers, 3 had previous TBI history. Our findings showed that the boxers scored in the MMSE and verbal fluency below the expected average for schooling, which would be 26 and 13 points, respectively. **Conclusion:** In general, the boxers performed within the normal ranges in the tests, except for MMSE and VF. Of the 9 boxers, 5 presented hippocampal asymmetry, consisting with the memory complaints. Three of 9 boxers presented neurological alterations - had parkinsonian syndrome. This can be explained by the mechanism of head trauma they suffer in boxing.

Long-term outcome of Guillain-Barré syndrome associated with zika virus infection

Mario Emílio Teixeira Dourado Junior[1], Heric Weverton dos Santos[1], José Victor de Carvalho Dantas[1], Fátima de Menezes Dantas[1], Miguel Inácio Silva Gomes[1], Cássio Ricardo de Medeiros Souza[1], Selma Maria Bezerra Jerônimo[1]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.

Correspondence: Mario Emilio Teixeira Dourado Junior; Email: medourado03@gmail.com.

Background: The incidence of Guillain-Barré syndrome (GBS) has increased in Brazil since 2015, which initially was speculated to be secondary to the ZIKV and other newly introduced pathogens. The prognosis and overall outcome of Zika virus-associated GBS remain unclear. **Objective:** To investigate long-term neurological residua after GBS after ZIKV infection in the state of Rio Grande do Norte, Brazil **Methods:** The study included all GBS subjects diagnosed in 2015. Cases were considered having ZIKV disease if they had a rash with at least two other ZIKV-like symptoms in addition to positive anti ZIKV IgM or IgG. Information on signs or symptoms during the acute phase of the disease was retrieved from medical records. Patients were personally interviewed and re-examined or were contacted by phone 3 to 9 years after disease onset about residual symptoms and changes in daily living. Disability and handicap were assessed using the Hughes scale. **Results:** 34 patients were diagnosed with GBS during this period, 22 (64.7%) were included and examined at mean 52.81 months (SD 28.84) after disease onset. In the acute phase: mean age, years, was 44.41 mean (SD 15.79); 11 (50%) gender male; AIDP was the most frequent subtype, 18 patients (81.1%). The nadir varied from one day to 3 to 25 days (mean 8.5; SD 5). At that time 15 (68.18%) were severely disabled (grades 4 or 5 of the Hughes' scale). Four (18.8%) participants required ventilator support. All received IVIG treatment. At follow-up, the facial paralysis found in 3 (13.6%) participant and 3 (13.6) participants experienced paresthesia. 18 (81.8%) participants had completely recovered (Hughes 0); 3 (13.6%) patients able to run with minor signs or symptoms (Hughes 1) and 1 (4.5%) participant were incapable of running (Hughes 2). **Conclusion:** Over 90 % of GBS patients diagnosed when ZIKV was first introduced in Brazil had a more or less complete functional recovery. These data suggest that long-term outcomes and prognosis of Zika virus-associated GBS do not differ in severity from GBS due to other triggers., but of also importance was the prompt IVIG treatment provided timewise.

Long-term survival of an 11-year-old boy with brainstem ganglioglioma associated with severe obstructive and central sleep apnea

Sayuri Aparecida Hirayama[1], Mariana Graça Nasr[2], Maria Clara Foloni[1], Rodrigo de Carvalho Pazeto[1], Lucas Martins Teixeira[1], Letícia Lambert[1], Gilmar Fernandes do Prado[1], Karla Carlos[1]

[2]Hospital Central da Aeronáutica, Rio de Janeiro RJ, Brazil.

Correspondence: Sayuri Aparecida Hirayama; Email: sah.hirayama@gmail.com.

Case presentation: An 11-year-old boy experienced intense snoring since the age of 5, along with waking up at night with difficulty breathing and restless sleep. By the age of 6, he also had excessive drooling, swallowing difficulties, and vertigo with an unsteady gait trending downward to the left. At 7, he started complaining of severe headaches. An MRI discovered a wide lesion spreading from the medulla to the fourth ventricle and upper cervical spinal cord. He was referred to Neurosurgery with the final diagnosis of brainstem ganglioglioma (WHO grade 1). After starting chemotherapy, the patient was referred to our service for desaturation and dyspnea during sleep. Polysomnography revealed an obstructive sleep apnea (OSA) index of 90.8 and a central sleep apnea (CSA) index of 22.1, with a severe desaturation of 61%. The CPAP (continuous positive airway pressure) titration was recommended and a pressure of 10 cmH2O abolished the obstructive apneas without changing the central apneas. Tracheal dead space increasing (respiratory center CO2 modulation) was also inefficient. He started CPAP treatment, what improved some of his symptoms, but his mother observed peripheral desaturations of up to 69% with tachycardia. Upon waking up, he presented symptoms of carbonarchosis, requiring frequent in-hospital noninvasive ventilation. Hospitalizations were also needed due to infections. Once the CPAP machine monitoring system persistently showed high central apnea index, supplemental nocturnal oxygen was recommended and a servo-ventilation titration was performed, aiming to treat central and obstructive sleep apnea, that was succesful with a EPAP = 6, PS = 6 to 13 cmH2O. **Discussion:** Patients with brainstem gangliogliomas typically had only a few months of survival after surgery. Our patient has completed one year of follow-up in our service, showing significant improvement in his oncological condition, school activities, and marked body development. CSA is a rare disorder in children, but it can be associated with underlying conditions such as brain tumors. Gangliogliomas are rare tumors accounting for 0.33-1.3% of all primary brain tumors, mostly affect children and young adults. Only 3% of gangliogliomas occur in the brainstem. Symptoms of children with brainstem gliomas vary depending on the location of the lesion. In our case, the tumor was located in the medula oblongata, which contains the respiratory center. The treatment of CSA depends on the severity of symptoms but includes optimization of underlying etiology. The best option for our patient was surgery, followed by servo-ventilation, and we believe that his long-term survival relies on this approach. **Final comments:** CSA is a rare disease in the pediatric population. Detailed history taking and complementary exams, such as polysomnography, should be performed, and a thorough etiological investigation should be conducted. Individualized management can improve CSA and the clinical condition in most patients.

Loss of bilateral voluntary eyelid opening in a patient with bilateral thalamic infarction: apraxia or dystonia? A case report

Thamires Marx da Silva Santos[1], Rodrigo Santiago Gomez[1], Ricardo Oliveira Horta Maciel[1], Leonardo Dornas de Oliveira[1], André Luis de Oliveira Silveira[1], Italo Pena Guimarães[1], Nathália Luísa Carlos Ferreira[1], Gustavo Carvalho Oliveira Gonçalves Machado[1], Maria Luiza Nóbrega Lima de Albuquerque[1], Sabrina Gesteira Souza[1]

[1]Universidade Federal de Minas Gerais, Belo Horizonte MG, Brazil.
[2]Universidade Federal de Minas Gerais, Hospital das Clínicas, Belo Horizonte MG, Brazil.

Correspondence: Thamires Marx da Silva Santos; Email: marxthamires@gmail.com.

Case presentation: We report the case of a 72-year-old male patient admitted with sudden onset of mental confusion and inability to open both eyelids. He had a history of alcohol and tobacco use, hypertension, and coronary artery disease, with no prior cognitive impairments reported. Upon admission, he exhibited disorientation and confused speech without signs of aphasia, slight left hypotropia without diplopia, and an inability to voluntarily open his eyelids, with evident contraction of the frontal muscles during attempts and no involuntary eyelid contractions, raising the possibility of eyelid opening apraxia. Magnetic resonance imaging showed posterior circulation infarction with bilateral thalamic involvement. Electromyography (EMG) of the levator palpebrae superior muscles, which were functional, and the orbicularis oculi muscles, which showed sustained contraction at rest, was performed. One month after the ictus, the patient showed partial improvement, spontaneously opening about one-third of his eyelids, but continued to have cognitive deficits. **Discussion:** Eyelid opening apraxia is defined as a non-paralytic motor disorder characterized by difficulty in voluntarily opening the eyelids in the absence of visible contraction of the orbicularis oculi muscle, but its classification as true apraxia is debatable. EMG studies suggest that the pathophysiology of this phenomenon involves involuntary inhibition of the levator palpebrae superior muscle and/or sustained contraction of the orbicularis oculi muscle. Under normal conditions, the contraction of the levator palpebrae superior muscle leads to the reciprocal relaxation of the orbicularis oculi muscle, allowing eyelid opening. In the reported case, sustained contraction of the orbicularis oculi muscle prevented its relaxation, despite the functioning of the levator palpebrae superior muscle, thereby hindering eyelid opening. According to the literature, this observed pattern may be more appropriately classified as blepharospasm-related eyelid dystonia. The anatomical bases are not well defined, but there is evidence of an association with alterations in the basal ganglia, the rostral midbrain and the frontal lobes. Case reports in patients with bilateral thalamic infarction suggest that the paramedian thalamic nuclei may play a role in the neural network responsible for voluntary eyelid movements. **Final comments:** The loss of voluntary eyelid opening is a rare condition that can significantly impair patient functionality. Its pathophysiological and anatomical bases are not fully understood and may present different patterns, making the term eyelid opening apraxia inappropriate. More EMG and functional imaging studies are needed to better characterize this condition.

https://doi.org/10.5327/CBN241054

Low frequency repetitive stimulation as a tool to differentiate Eaton-Lambert myasthenic syndrome from myasthenia gravis

Lucas Marenga de Arruda Buarque[1], Nicolas Ruan dos Santos Cavalcante[1], Jose Pedro Soares Baima[1], Ian Felipe Barbosa Souza[1], Stefano Machado[1], Fernando Cavalcanti de Sá e Benevides Falcão[1], Andre Macedo Serafim da Silva[1], Rodrigo de Holanda Mendonça[1], Carlos Otto Heise[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Lucas Marenga de Arruda Buarque; Email: l.marengabuarque@gmail.com.

Background: It's has long been stated that high frequency repetitive stimulation (HFRS) is a valuable tool to differentiate myasthenia gravis (MG) from Lambert-Eaton Myasthenic Syndrome (LEMS), nevertheless it is not performed routinely in neuromuscular junction (NMJ) studies. **Objective:** We describe the use of low frequency repetitive stimulation (LFRS) with a train of six stimuli in order to differentiate between LEMS and MG with antibodies to acetylcholine receptor (AChR). **Methods:** The ratio of the 4th and the 6th amplitude potential were compared between 04 patients diagnosed with LEMS (group 1) and 11 MG AChR patients (group 2). **Results:** The amplitude ratio was 1.21 in group 1 and 0,92 in group 2. Of 11 patients in group 2, only one had a decremental index above 1; and, in group 1, only one patient had a decremental index under 1, with whom was diagnosed myasthenia gravis lambert-eaton overlap syndrome. **Conclusion:** We suggest that an amplitude ratio above 1 in LFRS (train of 6 stimuli) in patients with a neuromuscular junction syndrome for screening LEMS. A relation above 1.0 of the 4th and the 6th amplitude potential is suggestive of LEMS.

https://doi.org/10.5327/CBN241055

Lower pain and reduced strength in lower limbs as a complaint in stiff-person syndrome, a rare autoimmune condition: a case report

Victor Xavier da Silva[1], Camila Maria Barreto Ribeiro[1], Lucas Vergne Cheade Lins[1], Julia Cordeiro Braga[1], Adriana Alves Rapp[1], Marcel Leal Ribeiro[1], Brenda Francisca Cardoso Brito[1], Paulo Ricardo Sampaio de Melo[1], Karla Oliveira Couto[1], Eduardo de Oliveira Costa[1]

[1]Hospital Santa Izabel, Salvador BA, Brazil.

Correspondence: Victor Xavier da Silva; Email: victorxavier.vxs@gmail.com.

Case presentation: Patient 22 years old, male, with moderate low back pain, without other associated symptoms for 6 months, evolving for approximately 1 week with weakness in the lower limbs which he reports to be progressive in onset, with worsening for the last about 24 hours. Denies trauma, fever, weight loss. He had a previous diagnosis of Wolff-Parkinson-White syndrome. First-degree family member with vitiligo. In this context, the patient was admitted to a hospital unit for diagnostic elucidation. On admission physical examination, muscle strength was grade 5 in the upper limbs (UL) and grade 4+/5 in the lower limbs (LL), predominantly proximal. Grade 3 osteotendinous reflexes in the LL, with an increase in the reflex area and a discrete bilateral exhaustible Achilles clonus. Sensibilities preserved globally, without sensitive level. Preserved coordination. Bilateral plantar flexor cutaneous. Signs of pyramidal release present. MRI of the skull and spine showed no changes, CSF study showed protein-cytological dissociation (0.3 cells and 113 proteins) suspecting inflammatory polyradiculopathy, starting human immunoglobulin for 5 days, with clinical improvement. There was a search for neoplastic foci, rheumatological tests, myopathy markers (CPK, aldolase) in addition to serology, all of which were negative. After discharge from hospital within 90 days, he developed contractures and spasms in the lower back and right lower limb (RLL). Electroneuromyography demonstrated coactivation of agonist-antagonist muscles in RLL, without other changes, and a Stiff-Person syndrome (SPS) test was then carried out, with a posteriori reagent test for anti-GAD. Diazepam was started with symptom improvement and subsequent sessions of human immunoglobulin were scheduled, in addition to defining a rehabilitation strategy, screening for Type 1 Diabetes Mellitus (DM1) was negative. **Discussion:** Stiff person syndrome or SPS is an uncommon disorder characterized by progressive muscle stiffness, rigidity, and spasm involving the axial muscles, resulting in severely impaired ambulation. SSP is often associated with DM1, which may be a reflection of autoimmunity. Rarely occurring as a paraneoplastic syndrome. It has an estimated prevalence of 1-2 cases/1,000,000, and an incidence of 1 case/1,000,000/year. The majority of patients present between the ages of 20 and 50 years, being more common in women (ratio of 3:1). Diagnosis includes clinical characteristics and complementary exams. Some patients with SPS spectrum disorders require multiple immunological therapies. For example, intravenous immunoglobulin. **Final comments:** The case in question shows how presentations such as low back pain and complaints of weakness on the part of patients can, in fact, be attributable to other conditions, which in this case was attributed to the SPS condition, opportunely anticipating the diagnosis and so the treatment.

https://doi.org/10.5327/CBN241056

Lupus encephalitis: a case report

Rodrigo Batista Irikura[1], Anouar Sacca Colognesi[1], Bruna Santos Silva Guzzardi[1], Sarah de Souza Chinelato[1], Gustavo Carvalho Viveiros[1], Isabella Brasileiro Quintella Migueis[1], Guilherme Leonel Gomes da Cunha[1], Talles Camin Rajab[1], Fábio de Araujo Pereira[1], Luiz Henrique Soares Santos Stefano[1]

[1]Faculdade de Medicina de Marília, Marília SP, Brazil.

Correspondence: Rodrigo Batista Irikura; Email: rodrigoirikura@gmail.com.

Case presentation: A 65-year-old female patient was referred to the Emergency Department due to progressive functional decline that began 4 months prior. Previously healthy and independent, she started experiencing febrile episodes interspersed with fluctuations in consciousness and disorientation. After one month, she developed motor impairment with gait difficulties and reduced verbal interaction with family members, progressing to mutism and global spasticity over two months, becoming bedridden. Initial evaluation found no significant findings, prompting a referral to the Neurology team for further investigation. Neoplastic screening revealed no abnormalities. An electroencephalogram showed global slowing of waves with periodic complexes. Cerebrospinal fluid analysis showed normal cell count and a protein level of 70mg/dL. Laboratory tests indicated moderate anemia, thrombocytopenia, elevated erythrocyte sedimentation rate (ESR), anti-DNA at 1:160, high-titer anti-Ro positivity, and consumed complement levels, consistent with active Lupus. The patient was prescribed pulse therapy with methylprednisolone 1g for 5 days, resulting in transient improvement. Intravenous human immunoglobulin was then administered, leading to progressive improvement after the infusion began. The patient was discharged alert, oriented, communicative, and with grade IV strength globally. **Discussion:** Lupus is a chronic autoimmune disease characterized by periods of activity and remission, more prevalent in women under 40. Neuropsychiatric symptoms occur in about 40% of cases, with a minority involving mental status changes, constituting a medical emergency. Anti-DNA antibody positivity is associated with encephalitis targeting the NMDA receptor. Treatment focuses on disease control with continuous immunosuppression, often requiring multiple immunosuppressant classes. Prognosis varies depending on the extent of central nervous system involvement. **Final comments:** The patient had no prior diagnosis of any autoimmune disease, presenting with subacute changes in mental status and consciousness. She was admitted bedridden and mute, but showed significant clinical improvement and return of functionality with the instituted therapy. This case presented a diagnostic challenge and a robust clinical response, highlighting its relevance.

[2]Monash University, Melbourne, Australia.

Correspondence: Thais Maria Santos Bezerra; Email: t243567@dac.unicamp.br.

Background: Although cognitive dysfunction and structural brain changes have been described after Sars-Cov-2 infection, little is known about the impact of the severity of acute infection. Whether gray matter changes are severe enough to automatically differentiate between post-COVID and non-infected individuals is unknown, and neither is the power to classify individuals according to the acute severity of COVID infection. **Objective:** Here, we applied machine learning to investigate if grey matter alterations can distinguish between individuals after mild or moderate infections and non-infected controls. **Methods:** We acquired high-resolution T1-weighted images (3T) from 327 post-COVID subjects (285 mildly infected non-hospitalized and 42 moderately infected) and 151 healthy controls (non-infected) at the University of Campinas. The T1 images were segmented using Freesurfer 7.1.1, which yielded 68 cortical thickness measures and 14 subcortical volumes. Age and sex were normalized using a reference cohort of 37,407 individuals. Machine learning models were built using Python3 and scikit-learn. The final models were selected based on the area under the receiver operating characteristic curve (AUC), the f1 score, and accuracy. The reported results are from cross-validation scoring, and hyperparameter tuning was performed. **Results:** The SVM achieved an accuracy of 69.1%±0.6% in differentiating patients from controls based on thickness and subcortical volumes. This accuracy was observed to be 69.3% when both parameters were considered. In differentiating between mild cases and controls, SVM yielded accuracies of 66.1%±2.6% with thickness and 65%±1.8% with subcortical volumes, while 65.8%±2.5% was observed with both. The separation between moderate versus controls or mildly infected patients was not identified, as the f1-score was zero, despite the high accuracies observed on both (78.2% and 87.2%). **Conclusion:** The application of machine learning techniques enabled the differentiation between patients diagnosed with COVID-19 and those in the control group, as well as between patients exhibiting mild symptoms and those in the control group. These preliminary results indicate the potential for structural brain changes even after a mild infection. Additionally, the cortical and subcortical information appears to exhibit comparable patterns, as evidenced by the similar accuracies and the lack of significant improvement in results when both are included. As the disease progressed, the models were unable to differentiate moderate infected patients from controls or from mildly infected patients, despite achieving high accuracy rates, even after tuning the hyperparameters of the models. This is due to the fact that the dataset is severely imbalanced. Consequently, in the event of datasets exhibiting potentially intricate interactions between data points, all instances are ultimately classified as the majority class, resulting in a f1-score of zero.

Background: Although gray matter atrophy in temporal lobe epilepsy (TLE) has been repeatedly demonstrated, advanced in-vivo MRI analyses of cortical gyrification may aggregate information about complex pathological processes. A recent study validated a cortical folding universal model based on metrics of cortical thickness (T), total surface area (At) and exposed surface area (Ae), describing a universal scaling law: At*sqrt(T)=k*Ae^(5/4). This model was advanced to a vector base space describing the human cortex with 3 perpendicular and dimensionless variables: axonal tension (K), cortical shape complexity (S) and brain isometric size (I). So far, little is known about the pathological changes of these cortical variables in TLE and their capacity to discriminate subgroups. **Objective:** To compare pathological changes in newly derived measures between groups of mesial temporal lobe epilepsy (TLE) and healthy controls. **Methods:** Cortical measures were extracted from T1-weighted images of 337 controls and 165 patients (95 LTLE and 69 RTLE) using Freesurfer 7.4.1. Novel measures were derived with the CorticalFoldingAnalysisTool/MATLAB2019. Metrics I, K, and S were computed as scalar metrics of vectors that represented each lobe in a log-normalized space (At,Ae,T^2) as (1,1,1), (1,-5/4,1/4) and (3/2,3/4,-9/4), respectively. Value changes of I represent size, K represents tension/pressure and S represents shape. Metrics were corrected for age and sex and standardized relatively to the controls. Group differences were evaluated with repeated measures ANOVA and Bonferroni's post-hoc pairwise correction using SPSS26. Machine learning classification models were built to distinguish between groups using Python3/scikit-learn. Models were scored with 5-fold cross-validation using accuracy, f1-score, and area under the curve (AUC). **Results:** Compared to controls, bilateral hemispheres were affected in LTLE and RTLE. For LTLE, ipsilateral I for parietal and temporal lobes were reduced (p-value=0.03, p-value<0.001), and K for the temporal lobe was augmented (p-value<0.001). LTLE contralateral hemisphere had a bigger K for the temporal lobe (p-value<0.001). For RTLE, ipsilateral I for temporal (p-value=0.015) and occipital (p-value=0.033) lobes were reduced (p-value=0.015, p-value=0.033), while K for temporal and S for parietal lobe were augmented (p-value<0.001, p-value=0.006). RTLE contralateral hemisphere had a bigger S for the parietal lobe (p-value=0.005). Machine learning models consistently separated TLE patients and controls (AUC=0.71±0.02) and RTLE from LTLE (AUC=0.79±0.08) using logistic regression. **Conclusion:** Although both temporal ipsilateral regions were affected in TLE, side of hippocampal atrophy differed in disease progression, as different measures were abnormal for LTLE or RTLE. These metrics, although sparse, can distinguish TLE patients from controls.

Magnetic resonance imaging abnormalities in idiopathic intracranial hypertension: a study of 40 female patients

Annelise Akemi Higa Lee[1], Ana Carolina Montouro Storarri[1], Lorrane Campidelli Arthuzo[1], Luis Armando Sawada[1], Beatriz Marques dos Santos[1], Thassia Cavalcante de Oliveira Moraes Marques[1], Bruno Pissolati Mattos Gonzaga[1], Renan Barros Domingues[1]

[1]Santa Casa de Misericórdia de São Paulo, São Paulo SP, Brazil.

Correspondence: Ana Carolina Storarri; Email: anastorarri@gmail.com.

Background: Idiopathic intracranial hypertension (IIH) is a condition characterized by increased intracranial pressure with no detectable cause. MRI is an importat tool in diagnosing and understanding IIH, providing insights into the anatomical changes associated with this condition. This study aims to describe the MRI findings in a cohort of 40 female patients diagnosed with IIH. **Objective:** To evaluate the frequency and type of abnormalities detected on MRI in female patients with IIH. **Methods:** We conducted a retrospective analysis of MRI findings in 40 female patients diagnosed with IIH. The average age of the patients was 33.9 years (standard deviation of 11.5 years). The MRI abnormalities evaluated included sella turcica deformities, optic nerve abnormalities (including optic nerve tortuosity, distended optic nerve sheath, and optic nerve head protrusion), globe flattening, and transverse sinus stenosis. The data were analyzed to determine the prevalence of each abnormality. All the patients were evaluated at the Headache Outpatient Clinic of Santa Casa de Misericórdia de São Paulo. **Results:** The analysis revealed the following abnormalities:

- Sella turcica deformities in 14 patients (35%)

- Optic nerve abnormalities in 35 patients (87.5%)

- Globe flattening in 8 patients (20%)

- Transverse sinus stenosis in 14 patients (35%).

Conclusion: Our study demonstrates that optic nerve abnormalities are the most frequent MRI finding in female patients with IIH, observed in 87.5% of cases. This is a higher frequency compared to sella turcica deformities, which were present in 35% of the patients. These findings differ from other series in the literature, where sella turcica abnormalities are often reported as more common. This highlights the variability in anatomical manifestations of IIH and underscores the importance of comprehensive MRI evaluation in these patients.

Main factors related to the development of post-avc headache - a systematic review

Sávio Roberto Silva Costa[1], Fernando Gabriel dos Santos Santiago[1], Mariangela Moreno Domingues[1], Danusa Neves Somensi[1], Emanuel de Jesus Soares de Sousa[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Sávio Roberto Silva Costa; Email: saviorsc20@gmail.com.

Background: Stroke is one of the main causes of morbidity and mortality in the world. In Brazil, there is an estimated prevalence of 2,231,000 cases, and the prevalence of post-stroke disability is 29.5% for men and 21.5% for women. Among the clinical manifestations after stroke, headache is a common complaint, with observational studies showing frequencies of 11 to 39%. However, despite the high prevalence of post-stroke headache, few studies characterize it and relate it to predisposing factors. **Objective:** To identify which factors may predispose to the development of post-stroke headache. **Methods:** This is a systematic literature review based on the following guiding question: what are the main factors that can predispose to the development of post-stroke headache? The databases used were PubMed and Scielo. The descriptors were divided into two groups and permuted as long as one of each group was included in the search; thus, the groups were "disease": Stroke, Ischemic Stroke and Hemorrhagic stroke; "Sequela": headache disorder and headache; and their respective descriptors in Portuguese; the groups were joined by the Boolean operator AND. Full articles published between 2018 and 2022 were included. The PRISMA method was used to construct the review; in addition, the Joanna Briggs Institute tool was used to analyze the quality of the selected articles. **Results:** The studies showed a prevalence of headache after stroke of between 10.4% and 50% and converged on most of the characteristics, describing pain of moderate intensity and unilateral or bilateral localization of a pattern similar to tension headache. To a lesser extent, they identified nausea and photophobia associated with the headache, a typical symptom of migraine. However, these patients proved to be unresponsive to triptans, a common drug in the abortive treatment of migraine. In addition, patients who already had a headache before the stroke episode are more likely to develop post-stroke headache, which occurs with a change in the characteristics of the initial symptom. With regard to the location of the stroke and headache, only one study found a statistically significant relationship, with infarcts in the cerebellar region. It is also worth mentioning that good condition at the start of the stroke, lack of sleep, the presence of pathological changes in the intracranial arteries (mainly dissections) and strokes that affected large cerebral arteries are statistically significant factors in the development of post-stroke headache. **Conclusion:** Post-stroke headache is a chronic, recurrent condition that tends to be tension-type, moderate in intensity and unilateral or bilateral. It should also be noted that vascular pathologies may be closely related to this condition. More studies are needed to assess the relationship between topography and post-stroke headache.

Malignant brain neoplasms in the Brazilian midwest from 2014 to 2023: an epidemiological study

Gustavo Hayasaki Vieira[1], Giovana de Oliveira Araújo[1], Gustavo Cartaxo de Sousa Melo[1], Isabela Maciel Mesquita[1], Milena Almeida Barbosa[1], Paulo André Silva Miranda[1], Paulo Sérgio Machado Diniz[1], Rafaella Rodrigues de Freitas Vieira[1], Samira Dionísio Maia[1], Valentina Melo Rosa Centofanti[1]

[1]Pontifícia Universidade Católica de Goiás , Goiânia GO, Brazil.

Correspondence: Gustavo Hayasaki Vieira; Email: gushayasaki@gmail.com.

Background: Malignant Brain Neoplasms represent 1.4 to 1.8% of malignant tumors worldwide. It involves the proliferation of cells within the brain, presenting symptoms that vary depending on the location and extent of tissue involvement. Although rarely metastatic to other organs, this tumor can destroy brain tissue as it grows. Due to the scarcity of studies on malignant brain tumors in the Brazilian Midwest, it is important to conduct an epidemiological analysis of the patients of this region, focusing on identifying the frequency of this condition and enhancing diagnostic and treatment measures. **Objective:** To comparatively analyze the epidemiological profile of patients with Malignant Brain Neoplasms in the regions of the Brazilian Midwest. **Methods:** This is a descriptive, retrospective, and quantitative study based on data from the Hospital Information System (SIH/SUS), provided by the Department of Information Technology of the Unified Health System (DATASUS), regarding patients over the past ten years in Goiás, Mato Grosso, Mato Grosso do Sul, and Distrito Federal. Filters applied included: ICD-10 morbidity list (malignant brain neoplasms), midwest region, race/ethnicity, gender, age group, number of deaths, mortality rate, available period (January 2014 to December 2023), and year of data processing. Data were tabulated in Excel and subjected to descriptive statistical analysis using R 4.40 with RStudio 2024.04.1 + 748. Since this study utilizes publicly available anonymous data, it is exempt from the Ethics Committee's approval. **Results:** During the study period, 1,420 deaths were confirmed,

with an annual average of 142 deaths (±22.07). The year 2022 exhibited the highest mortality rate (12.88%), with indigenous populations being the most affected (25%). In this context, the state of Goiás had the highest number of deaths (40.99%), while Mato Grosso do Sul had the lowest (13.66%). However, Mato Grosso do Sul had the highest overall mortality rate (15.85%) and a 100% mortality rate among the Indigenous population. The age group with most deaths was 60-69 years (339 cases). Regarding hospitalizations, Goiás led with 41.4% of cases, while Mato Grosso do Sul had the lowest proportion, 9.94%. Furthermore, the disease was more predominant in males (761 cases) compared to females (659 cases). **Conclusion:** Indigenous people show the highest mortality rate and are a vulnerable community to the disease, reflecting the effects of social inequality, and territorial segregation. Moreover, the state of Goiás had the highest number of hospitalizations alongside the second lowest mortality rate. Despite having fewer deaths compared to Goiás, Mato Grosso do Sul has a smaller population, thus proportionally it is the most affected state by the disease as it exhibits the highest mortality rate. Further research is required to explore the causes of regional differences in hospitalizations and mortality rates throughout the Brazilian Midwest

Correspondence: Andre Felipe Candêas Amorim; Email: andfcamorim@gmail.com.

Case presentation: A 22-year-old man reports the beginning of pain and weakness in the lower right limb, affecting the contralateral limb a few days later. After 10 to 15 days, the patient started to need help to walk. In addition, progressively, he began to present numbness up to the nipple level bilaterally, associated with urinary retention and constipation. After 3 months, the patient noted neck pain, which intensified with head flexion radiating to the lumbar region. On examination, he presented hypotonia in the lower limbs. The strength was 0/5 bilaterally in the lower limbs and 4/5 in the upper limbs. About the reflexes Biceps, brachioradialis, triceps were 2/4 bilaterally and patelar and Achilles were 0/4 bilaterally. No clonus were presente and Cutaneous plantar reflex was absent bilaterally. Tactile, painful, proprioceptive and vibratory sensation were absent bilaterally up to the level of T6, remaining hypoesthesia in the left side up to C2. Lhermitte's sign was present. **Discussion:** Initially, a complete spinal cord syndrome was raised as a syndromic diagnosis. Due to the subacute presentation, mainly inflammatory and infectious conditions were identified as etiologies. The general lab revealed an VHS of 25mm/h. Rheumatological tests came back normal (Antinuclear antibody with dense fine speckled pattern 1:160; Negative Anti-dsDNA; Negative Rheumatoid Factor; Complement C2 fraction 122 (Normal), Total complement 103 (Normal). Serology showed a VDRL of 1:1 with a positive treponemal test that were seen as a serological scar, since the patient had previous treatment. In the sequence of investigation, a MRI was performed and revealed an extensive heterogeneous intramedullary lesion from the medulla oblongata to the conus medullaris, centrally located and tumefactive in appearance. It showed gadolinium enhancement and areas of hydrosyringomyelia. In the sequence, a cerebrospinal fluid was collected with the presence of 11cells/mm^3 of lymphomonocyte predominance, glucose 44mg/dL, protein 159mg/dL, lactate 22.71mg/dL, negative GeneXpert, negative microorganism cultures and research for neoplastic cells positive. At the end of the investigation, a spinal cord biopsy was performed and the anatomopathological analysis, together with immunohistochemistry, revealed a Malignant Neoplasm with a Small Cell morphological pattern, with an Embryonic Tumor as the main diagnosis. **Final comments:** The case above points to a rare differential diagnosis of cases of longitudinally extensive myelopathy. Thus, despite a rapid evolution over 3 months with involvement of the entire length of the spinal cord, which initially suggested an inflammatory or infectious condition, it was ultimately revealed to be an aggressive malignant neoplasm.

Management of myopathic symptoms with oral dantrolene in a pregnant patient susceptible to malignant hyperthermia

Gabriel Saboia de Araújo Torres[1], Mariana Hiromi Manoel Oku[1], Gabriella Correa Dousseau[1], Filipe Tupinambá Di Pace[1], Cristiane Araújo Martins Moreno[1], Clara Gontijo Camelo[1], Rodrigo de Holanda Mendonça[1], Edmar Zanoteli[1], André Macedo Serafim Silva[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Departamento de Neurologia, São Paulo SP, Brazil.

Correspondence: Gabriel Saboia de Araújo Torres; Email: gabriel.saboiat@gmail.com.

Case presentation: A 30-year-old female presented to the Neuromuscular Clinic with a history of muscle cramps, exercise intolerance, and fatigue since childhood, accompanied by persistently elevated creatine kinase (CK) levels reaching up to 2257U/L. She had presented a few events of myoglobinuria after physical efforts. Her physical examination did not reveal weakness or other associated findings. Whole exome sequencing revealed two variants in the RYR1 gene c.8197G>T; p.(Gly2733Cys) and c.7393G>A; p.(Asp2465Asn). Due to significant symptoms, treatment with oral dantrolene 25mg twice daily was initiated, resulting in substantial improvement in muscle cramps and post-exercise pain. Over subsequent months, the dose was adjusted to 25mg three times daily, leading to a reduction in CK levels to 237U/L. After two years of follow-up, the patient became pregnant with twins. Concerned about the safety profile of dantrolene, treatment was initially suspended, resulting in an increase in CK levels. Dantrolene was resumed at 29 weeks of pregnancy, leading to significant clinical and laboratory improvement. Despite a complex delivery at 36 weeks due to placental abruption and subsequent puerperal hemorrhage necessitating intensive care support for four days, the patient eventually recovered. Uterine hypotonia possibly related to dantrolene was considered. One month post-delivery, dantrolene was reintroduced with continued good response. Both children were born healthy and demonstrated normal neurodevelopmental milestones. **Discussion:** Malignant hyperthermia is characterized by a hypermetabolic state triggered by genetic variants affecting intracellular muscular calcium metabolism, notably in the RYR1 gene encoding the ryanodine-1 receptor responsible for calcium release from the sarcoplasmic reticulum during excitation-contraction coupling. Intravenous dantrolene is the cornerstone of acute malignant hyperthermia treatment, acting by blocking calcium release via the ryanodine receptor. Oral dantrolene has been explored in patients with RYR1 variants for managing muscle symptoms and reducing CK levels, showing promising results in case series. Limited literature exists on the use of oral dantrolene during pregnancy. The obstetric complications observed in our patient, including placental abruption and hemorrhage, may have been influenced by dantrolene use or the challenges inherent in a twin pregnancy, which carries a higher risk of peripartum complications. **Final comments:** Oral dantrolene appears beneficial in controlling symptoms of RYR1-related myopathy and malignant hyperthermia susceptibility, including during pregnancy. However, its safety in pregnant women warrants further investigation.

Management of neurogenic bladder and bowel as a strategy to reduce epileptic seizures in a child with congenital zika syndrome: case report

Larissa Coutinho de Lucena[1], Amanda da Silva Santos[1], Vitor dos Santos Rodrigues[2], Jhulia Thaysa Macena da Costa[1], Marília da Costa Paiva[1], Amanda Georgia Diniz de Campos[3], Milena Thaisa Silva de Lima[2], Fernanda Gomes Mourão[1], Gabriel Alves Mendes Vasiljevic[1], Lilian Lira Lisboa[1]

[1]Instituto Santos Dumont, Macaíba RN, Brazil.
[2]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.
[3]Centro Universitário Maurício Nassau, Aracaju SE, Brazil.

Correspondence: Larissa Coutinho de Lucena; Email: larissa.lucena@isd.org.br.

Case presentation: 8-year-old girl with congenital zika syndrome (CZS), born by cesarean section at 39 weeks, 2,116g, 38cm, cephalic perimeter of 29cm and Apgar of 5/8. She had alterations in the Central Nervous System (CNS) as evidenced by tomography, supratentorial hydrocephalus and calcification of the basal nuclei. At 14 months, she was diagnosed with pharmacoresistant epilepsy, with an average of 5 seizures a day despite taking Sodium valproate 50mg, Phenobarbital 40mg and Nitrazepam 5mg. Motor development has functional limitation level V by Gross Motor Function Classification System.The patient has severe diffuse spasticity, bilateral hip luxation, laryngeal stenosis, gastrostomy diet dependency and lack of intentionality in her movements. Regarding bladder and bowel function, ultrasound (USG) of the upper urinary tract showed no alterations, but urodynamics revealed a neurogenic bladder with low compliance, a cystometric capacity of 37% of that expected and hyperactivity from 28ml on.The urinary diary showed low water intake (300ml/day) and constant use of diapers (average of 14 per day). The bowel movement diary showed a bowel movement frequency of less than once a week with the use of laxatives, type 1 and 2 stools on the Bristol Scale and previous formation of fecaloma. There were no signs of urinary infection or renal failure in the laboratory tests. Treatment included behavioral approaches and daily parasacral neuromodulation (10 Hz, 300 ms, 30 minutes). The study was approved by the Ethics and Research Committee (CAAE 51865521.5.0000.0129) and funded by the CNPq/MCTI/FNDCT-18/202, UNIVERSAL (403498/2021-0). **Discussion:** after two months of treatment, water intake increased to 1 liter/day, bowel function improved with an average bowel movement frequency of 4 times/week without laxatives, and stools type 5 to 6 on the Bristol Scale. The use of diapers was reduced to 8 a day. From the tenth day of treatment, there was a reduction in the frequency of epileptic seizures, which ceased completely from the twenty-sixth day of neuromodulation. Studies indicate that there is a two-way communication between the CNS, the gut and the intestinal microbiota, influencing the production of neurotransmitters and inflammatory responses that affect the brain. Findings in the literature indicate that changes in diet, such as ketogenic diets, can reduce indicators of refractory epilepsy. These findings suggest that the reduction in epileptic seizures may be related to changes in water and food intake during behavioral therapy. **Final comments:** this case suggests the possibility of a relationship between epilepsy and urinary and bowel dysfunction in children with CZS. These findings indicate the importance of proper management of urinary and bowel dysfunction in this population in order to reduce or control the epileptic seizures that are so frequent.

https://doi.org/10.5327/CBN241065

Management of NMOSD in Brazilian public scenario

Rafaela Pessoa Alves Luso[1], Izabela Cristina de Faria Martins[1], Rodrigo Gonçalves Kleinpaul Vieira[1], Jessica Vaz de Melo[1], Gustavo Carvalho Oliveira Gonçalves Machado[1], Maria Luiza Nobrega Lima Albuquerque[1], Alexandra de Oliveira Lopes[1]

[1]Universidade Federal de Minas Gerais, Belo Horizonte MG, Brazil.

Correspondence: Rafaela Pessoa Alves Luso; Email: lusorafaela@gmail.com.

Background: Neuromyelitis optica spectrum disorder (NMOSD) is an uncommon immune-mediated disease that affects the central nervous system and presents with relapses frequently leading to disability. Cases clinically manifested as NMOSD may include aquaporin-4 antibody (AQP4-Ab) seropositive disease, myelin oligodendrocyte glycoprotein antibody disease (MOGAD), and double-seronegative disease. Diagnosis is based mainly on core clinical features, but serologic testing and magnetic ressonance imaging should be evaluated. These exames, as well as most therapies available are costly, therefore managing NMOSD in the public scenario of emerging countries represents a challenge. **Objective:** Analyze epidemiological data from a Brazilian cohort in a neuroimmunology referral public service in Belo Horizonte (Minas Gerais) and establish correlations about challenges regarding diagnosis and treatment. **Methods:** This study was retrospective and observational, analyzed data from electronic medical records from patients at a neuroimmunology referral service from January 2022 to June 2024, including demographic information, laboratory findings and treatment. Patients aged between 18 and 70 years were included, who had a neurological event suggestive of relapse and met the MOGAD and the NMOSD criteria. Patients with multiple sclerosis were excluded. Descriptive analyses of numerical and categorical data were conducted. **Results:** The sample included a total 32 patients, comprising 28 women and 4 men, with mean age of 43 years, 25% AQP4-Ab seronegative disease, 46% AQP4-Ab seropositive disease, 13% MOGAD, 13% double-seronegative disease and 3% did not undergo any sorological testing. Among current treatments prescribed to prevent relapses in NMOSD, azathioprine was the most used immunotherapy (31%). It was discontinued due to irregular use associated with financial matters, myelotoxicity and hepatotoxicity. Cyclophosphamide was the next choice (16%), discontinued mostly due to accumulated dose, but also due to hepatotoxicity. Rituximab, steroids alone and methotrexate were also prescribed. **Conclusion:** This study shows that access to targeted antibody testing remains limited in Brazil, even at referral services, postponing definitive diagnosis and treatment in many cases. Cyclophosphamide and steroids are available in the public health system at a tertiary center, but these do represent long term solutions. Azathioprine and Rituximab have shown to reduce relapses and disability, but are hard to maintain due to its high costs. There is urgent need for better options to treat NMOSD and MOGAD patients in the public scenario in Brazil, including hope for Humanized Monoclonal Antibody for aggressive and refractory AQP4-Ab disease. This strategy might prove to be cost-effective since it is expected to reduce expenses regarding young adults disabilities, hospital admissions and relapses treatments.

Management of severe intracranial hypertension in a patient with cerebral venous thrombosis

Ana Carolina Montouro Storarri[1], Annelise Akemi Higa Lee[1], Renan Barros Domingues[1]

[1]Hospital Samaritano Paulista, São Paulo SP, Brazil.

Correspondence: Ana Carolina Storarri; Email: anastorarri@gmail.com.

Case presentation: We report the case of acute management of intracranial hypertension with lumboperitoneal shunt in a young, obese, smoker female patient, who presented with an acute case of intracranial hypertension, with headache, nausea, vomiting, diplopia, papilledema and severe bilateral visual loss (counting fingers less than 1 meter) secondary to extensive venous thrombosis involving the right sigmoid sinus and internal jugular vein. Upon admission, the patient underwent neuroimaging with study of intracranial vessels (magnetic resonance imaging and magnetic resonance venography) in addition to a diagnostic lumbar puncture - the latter showing an opening pressure greater than 100 cm H2O. Initial management included anticoagulation with heparin. Despite this, the patient worsened the signs of elevated intracranial pressure (ICP) and progressive neurological deterioration. To manage the intracranial hypertension, high-dose acetazolamide was administered, providing partial relief of symptoms. Mannitol was also used intermittently to reduce acute spikes in ICP. However, due to persistent elevated ICP and the risk of permanent visual loss and herniation, a lumboperitoneal shunt was placed. This intervention resulted in significant clinical improvement and stabilization of the patient's condition. **Discussion:** Intracranial hypertension (ICH) is a common complication of cerebral venous thrombosis (CVT). The management of ICH in CVT is complex and requires a tailored approach. Recommendations regarding the management of intracranial hypertension in cerebral venous thrombosis are scarce due to the lack of controlled studies. High-dose acetazolamide can be effective in reducing ICP by decreasing cerebrospinal fluid (CSF) production. Mannitol, an osmotic diuretic, is useful for acute reduction of ICP but must be used cautiously due to potential side effects. In some cases of ICH, relief lumbar punctures are an option, however, in this case this strategy would be incompatible with the need for full anticoagulation. In cases where medical management is insufficient, surgical options such as lumboperitoneal shunting offer an alternative to alleviate pressure and prevent neurological deterioration. **Final comments:** This case underscores the importance of a comprehensive management strategy for intracranial hypertension in cerebral venous thrombosis, integrating pharmacological and surgical interventions. Each case requires individual assessment to determine the most effective combination of treatments, aiming to mitigate the risks and enhance patient outcomes.

Marchiafava-Bignami disease: a diagnostic challenge

Roberta Monteiro de Souza[1], Carolina Rocha da Silveira Brugger Cardoso[1]

[1]Universidade Federal do Rio de Janeiro, Instituto de Neurologia, Rio de Janeiro RJ, Brazil.

Correspondence: Carolina Rocha da Silveira Brügger Cardoso; Email: carolinarbrugger@gmail.com.

Case presentation: A 43-year-old female presented behavioral changes after irregular follow-up of bariatric surgery, in 2018. The patient started drinking excessively and taking prescription medications without supervision. In 2019, she was found unconscious at home, being admitted to the ICU for further investigation, but no neurological or psychiatric diagnosis was found at the time. Since then, family members have observed a progressive worsening of her cognition, behavior and functionality. Her neurological exam was difficult due to lack of cooperation, but it was seen an ataxic gait, Romberg sign falling backwards, slowed saccades, dysarthria, global hyperreflexia. In cognitive screening, she scored: Mini-Mental State Examination 13/30; Clock drawing test 0/5; Verbal Fluency Test by semantic category (2 animals) and by phonemic (0 "F" words). Brain MRI (2020) showed hypersignal in T2 and FLAIR in the splenium of the corpus callosum. Accentuation of cerebellar grooves and cisterns, disproportionate to the age group. The newest brain MRI (2024) showed diffuse thinning of the corpus callosum, generating ectasia of the lateral ventricles, associated with areas of low and high signal affecting its extension on FLAIR. **Discussion:** Marchiafava-Bignami disease (MBD) is a rare disorder of demyelination or necrosis of the corpus callosum and adjacent subcortical white matter. It is associated with alcoholism, malnutrition or both together, generating vitamin deficiencies, particularly vitamin B1. The course may be acute, subacute or chronic. Patients frequently show an altered mental state, which include confusion, delirium, unconsciousness, impaired memory and/or disorientation. Impaired walking, dysarthria, mutism, pyramidal signs, primitive reflexes, rigidity, incontinence, sensory symptoms, gaze palsy or diplopia, psychotic disorders and seizures were also described. Progressive dementia is the major clinical manifestation of the chronic form. The diagnosis is essentially clinical and radiological. In general, MBD is characterized by hyper-intense lesions without mass effect within the corpus callosum accompanied by swelling of the genu and splenium. In some cases, the anterior and posterior commissures, centrum semiovale and other white matter tracts may also be affected. Treatment involves replacement of B complex vitamins, in order to avoid disease progression. Some authors recommend treatment with corticosteroids, proposing that it prevents the demyelination process. **Final comments:** The current lack of knowledge about the mechanisms underlying demyelinating lesions of the corpus callosum is a barrier to establishing an effective therapy. Also, it is important to pay greater attention to alcoholic patients, in order to avoid serious nutritional deficiencies which can impact their functionality. Furthermore, new approaches for the prevention, early diagnosis and treatment of MBD are essential.

https://doi.org/10.5327/CBN241068

Marchiafava-Bignami disease: a case report with favorable outcome occurred in a quaternary hospital in Southern Minas Gerais in the year 2022

Joselene de Sales Costa[1], Augusto Cesar Marrafon[1], Bruna Mendanha Reis[2], Carla Hawthorne Reis[2], Tamiris Araujo Silva[1], Franciane Couto Soares[1], Ana Clara Rodrigues Santos[1], João Batista Macedo Vianna[1], Lucas Porto Ferreira[1], Luiza Serafini Balestrassi[1]

[1]Hospital de Clínicas de Itajubá, Itajubá MG, Brazil. [2]Faculdade de Medicina de Itajubá, Itajubá MG, Brazil.

Correspondence: Joselene de Sales Costa; Email: joselenesales.c@gmail.com.

Case presentation: LAR, 50 years old, male, right-handed, diabetic, hypertensive, chronic alcoholic for 28 years, smoker, epileptic and under investigation for polyneuropathy. Admitted on 09/04/2022, appearing disoriented, with periods of psychomotor agitation interspersed with drowsiness and torpor and unable to walk. On neurological examination, he appeared drowsy, disoriented in time and space. Presence of optic ataxia and right esotropia, dysarthric. Active movement of all four limbs, overall reduced strength, MRC grade 3, heightened deep tendon reflexes, with bilateral Babinski sign. Presence of appendicular and trunk ataxia. Laboratory tests: Elevated mean corpuscular volume and mean corpuscular hemoglobin, thrombocytopenia. Head CT: Hypoattenuation throughout the corpus callosum. Magnetic resonance: Diffusion restriction throughout the corpus callosum, hyperintense lesion in the corpus callosum and bilateral subcortical

frontal region, symmetric periventricular edema, typical of Marchiafava-Bignami disease, corroborating the diagnosis. The patient received intravenous B complex and oral thiamine supplementation, presenting clinical and neurological improvement during hospitalization. On the day of hospital discharge, he was alert, with improvement in muscle strength, MRC grade 4, deep tendon reflexes alive in the upper limbs and normoactive in the lower limbs, ataxic, indifferent plantar cutaneous reflex. Still disoriented in time and space and unable to walk. He was discharged from hospital with vitamin supplementation and outpatient follow-up. After three months, at a return visit, he presented normal laboratory tests, superior cortical function and cranial nerves without changes; muscle strength grade 4+; normoactive deep tendon reflexes in the upper limbs and decreased in the lower limbs; preserved appendicular coordination; bilaterally indifferent cutaneous-plantar reflex and ataxic gait. **Discussion:** Marchiafava-Bignami syndrome results from the neurotoxicity of alcohol and deficiency of B vitamins, mainly B12. The clinical presentation varies, with reports of interhemispheric disconnection syndromes and possible synergy with Wernicke's encephalopathy, as in this case. The imaging findings corroborate the diagnosis, showing characteristic changes in the corpus callosum. Treatment typically involves B complex, thiamine and folic acid supplementation, as performed in this case. In summary, favorable results are attributed to rapid initiation of treatment, cessation of alcohol consumption, adequate nutrition. **Final comments:** Although rare, Marchiafava-Bignami syndrome is a serious and potentially fatal condition, highlighting the importance of immediate diagnostic investigation and appropriate treatment. In this case, rapid diagnosis and treatment led to a favorable outcome. Case reports like this contribute to raising awareness about this disease, the importance of early treatment, differential diagnoses and management strategies.

Mechanical thrombectomy in an extended window for more than 24 hours: a case report

Camilla Vanessa Araújo Soares[1], Ana Luísa Castelo Branco Gomes[2], Tiago César Costa da Silva[1], Luciano Gonçalves do Nascimento Júnior[2], Felipe Nunes de Araújo[2], Gilmar Leite Pessoa Filho[2], Matheus Gurgel Saraiva[2], Juliana Magalhães Leite[2], Rafael Gonçalves[2], Alex Tiburtino Meira[3]

[3]Universidade Federal da Paraíba, Departamento de Medicina Interna, João Pessoa PB, Brazil.

Correspondence: Camilla Vanessa Araújo Soares; Email: camilla.vanessa46@gmail.com.

Case presentation: A 53-year-old male patient with a history of heart failure with decompensated reduced ejection fraction presents with right facio-brachio-crural hemiplegia, global aphasia and combined gaze deviation on the left. On admission, he had an NIHSS of 24. Head computed tomography showed a hypoattenuating area in the subcortical region of the left precentral gyrus, ASPECTS 9; and computed tomography angiography revealed occlusion of probable thrombotic nature in the proximal third of the cervical segment of the left internal carotid artery, with absence of flow in the distal cervical and intracranial segments and in the horizontal segment (M1) of the ipsilateral middle cerebral artery, in addition to the carotid web. Given the diagnosis of ischemic stroke, mechanical thrombectomy (MT) was performed 24 hours and 40 minutes after the ictus. MT was performed with total opening of the left internal carotid, left middle and anterior cerebral arteries, with total reperfusion (TICI III) of the aforementioned arteries. The patient's neurological status improved significantly after the interventions and he was discharged with an NIHSS of 0. **Discussion:** Ischemic stroke is an acute focal insult, which is characterized by impaired arterial supply to the cerebral territory. It is the second cause of morbidity and mortality in Brazil. In the absence of contraindications, treatment should be carried out with intravenous thrombolytics and MT, the latter being the standard treatment in of large vessel obstruction in the anterior circulation within 6 hours of ictus. Studies in developed countries have already shown that there is benefit in performing the procedure within an extended window of up to 24 hours, but there is still no solid evidence of benefit beyond this interval. In this case, the patient presented ASPECTS 9 even 24 hours after the ictus, which favored to MT despite exceeding the extended window time. Extending the therapeutic window is important, especially in developing countries, as it allows more patients to have access to the procedure. Considering that patients in the sistema único de saúde have less access to rehabilitation due to the long queues and that many users have difficulty accessing services within the ideal time window, it is interesting to consider the extended window in selected cases. However, it is a procedure that is prone to complications, which requires qualified professional to make decisions like this. **Final comments:** Early diagnosis is essential to determine the therapy to be initiated, whether thrombolytic or MT, with time being a crucial factor to avoid serious and irreversible neurological sequelae. However, in selected cases, MT may be beneficial if performed in an extended window. This case is relevant because of the therapeutic success of performing MT after the extended 24-hour window.

Median nerve impairment in leprosy: how does it differ from the classic carpal tunnel syndrome?

Lucas Figueira Vieira[1], Caio Luiz Nazar Cunha[1], Ana Clara Nogueira Cezar[1], Ariane Aparecida Correa de Miranda[1], Laura Caroline Felipe de Freitas[1], Eduardo William Farinha Carvalho[1], João Paulo Moreira Fernandes[1], Pedro Henrique Sirotheau Corrêa Alves[1], Isabela Maria Bernardes Goulart[1], Diogo Fernandes dos Santos[1]

[1]Universidade Federal de Uberlândia, Uberlândia MG, Brazil.

Correspondence: Lucas Figueira Vieira; Email: lucasfigueira@ufu.br.

Background: Carpal tunnel syndrome (CTS) has already been described as a possible form of neural leprosy presentation. However, the median nerve can be involved in this neuropathy in proximal segments and, sometimes, with an asymmetric impairment of the digital branches. **Objective:** To detail the pattern of median nerve impairment through a careful electroneuromyographic and ultrasound evaluation. **Methods:** This cross-sectional study comprises two groups, encompassing 15 primary neural leprosy (PNL) patients and 14 patients with CTS who underwent peripheral nerve ultrasonography and electroneuromyography evaluation. The median nerve was evaluated at the tunnel (Mt) and 4cm proximal to the carpal tunnel (Mpt). **Results:** 92.8% of patients with CTS and 80.0% of patients with PNL had bilateral impairment of the median nerve, totaling 27 nerves affected in each group. Considering the cross-sectional area (CSA) of the Mt segment, 63.0% of the nerves with CST and 74.1% of the nerves in the PNL group were found to be thickened, with an average CSA of 13.4 (± 4.4) and 12.4 (±4.6) respectively (p=0.18). The CSA of the Mpt segment showed the presence of thickening in only 3.7% in the CST group and 96.3% in the PNL group (p<0.0001), with an average of 6.6 (±1.3) and 17.0 (±6.7) respectively (p<0.001). 88.9% of the nerves in the PNL group and only 7.4% (2/27) showed a reduction in conduction velocity in the distal forearm, with an average of 41.0 (±6.3) and 53.2 (±5.2), respectively (p<0.0001). **Conclusion:** The presence of neural thickening and demyelinating impairment in the segments proximal to the carpal tunnel favors the diagnosis of leprosy.

Correspondence: Gabriel de Marco; Email: gabrieldemarx@gmail.com.

Bacterial meningitis is considered a life-threatening condition with high mortality rates. In response to the infection, signaling cascades, producing pro-inflammatory mediators trigger an exacerbated host immune response. Another inflammatory pathway occurs through the activation of inflammasomes. Studies highlight the role of the NLR family pyrin domain containing 3 (NLRP3) in central nervous system disorders commonly involved in neuroinfammation. We aimed to investigate the role of NLRP3 and its inhibitor MCC950 on neurochemical, immunological, and behavioral parameters in the early and late stages of experimental pneumococcal meningitis. For this, adult male Wistar rats received an intracisternal injection of Streptococcus pneumoniae or artifcial cerebrospinal fuid as a placebo. The animals were divided into control/saline, control/MCC950, meningitis/saline, and meningitis/MCC950. Immediately after the meningitis induction, the animals received 140ng/kg MCC950 via intracisternal injection. For the acute protocol, 24 h after induction, brain structures were collected to evaluate cytokines, NLRP3, and microglia. In the long-term group, the animals were submitted to open feld and recognition of new objects tests at ten days after the meningitis induction. After the behavioral tests, the same markers were evaluated. The animals in the meningitis group at 24 showed increased levels of cytokines, NLRP3, and IBA-1 expression, and the use of the MCC950 signifcantly reduced those levels. Although free from infection, ten days after meningitis induction, the animals in the meningitis group had elevated cytokine levels and demonstrated behavioral defcits; however, the single dose of NLRP3 inhibitor rescued the behavior defcits and decreased the brain infammatory profle.

Meningeal carcinomatosis in gastric cancer: a case series and narrative review from a single center in Brazil

Gabriela de Oliveira Tavares[1], Letícia Dias Costa[1], Thales Pardini Fagundes[1]

[1]Fundação Pio XII, Hospital de Câncer de Barretos, Barretos SP, Brazil.

Correspondence: Thales Pardini Fagundes; Email: pardinithales@gmail.com.

Background: Leptomeningeal carcinomatosis (LC) is a rare and devastating complication of cancer, affecting approximately five to ten percent of patients with solid tumors, with particularly low incidence in gastric cancer (0.14 to 0.24 %). This study presents the first case series of LC in gastric cancer in Brazil, combined with a comprehensive literature review to contribute to the understanding of this condition. **Objective:** To describe the clinical course of patients with gastric cancer who developed LC through the first Brazilian case series and a literature review. To conduct a literature review on LC in gastric cancer, describe possible clinical, laboratory, and imaging findings that aid in diagnosis, and explore the best therapeutic approaches. **Methods:** This study combines the first Brazilian case series of patients diagnosed with LC from gastric cancer in a single center with a comprehensive literature review. A literature search was conducted using the Virtual Health Library (BVS) database, with no period restrictions, limited to articles in English and Spanish. Data extracted included age, sex, histological type, MRI findings, CSF analysis results, treatment regimens, survival time, and presenting symptoms. These data were combined with additional cases managed by the authors. Descriptive statistics were used to summarize the data. **Results:** Nine patients with LC from gastric cancer were analyzed, including six cases from the literature and three novel cases managed by the authors, representing the first Brazilian case series. The median age was 56 years (range: 32 to 84 years), with a predominance of females (7 out of 9). The most common histological type was adenocarcinoma (7 out of 9), followed by signet ring cell carcinoma (2 out of 9) and early-stage gastric cancer (1 out of 9). MRI findings varied, with several cases showing leptomeningeal enhancement, while others presented unremarkable or negative findings. CSF analysis frequently revealed the presence of malignant cells or adenocarcinoma, confirming the diagnosis of LC. Treatment regimens were diverse and included intrathecal chemotherapy with agents such as methotrexate, cytarabine, and prednisolone, systemic chemotherapy, radiotherapy, and targeted therapy. Three patients received no treatment. The median survival time was two months (range: 0.5 to 29 months). **Conclusion:** This study provides valuable information on the clinical characteristics, diagnostic findings, therapeutic approaches, and outcomes of patients with LC from gastric cancer, presenting the first Brazilian case series. Further research is needed to improve the management of this rare and challenging complication.

Meningococcal disease and vaccination in the child and youth population in Brazil (2010-2022): an epidemiological study

Maria Eduarda Garcia Marvulle[1], Gabriella de Oliveira Barboza[1], Thairon Guilherme de Santana[1], Victória Maria Rabelo Lopes[1]

[1]Universidade de Marília, Marília SP, Brazil.

Correspondence: Maria Eduarda Garcia Marvulle; Email: mariaeduardamarvulle@outlook.com.

Background: Meningococcal disease, with meningitis as a common presentation, is caused by Neisseria meningitidis, with serogroup C being the most prevalent in Brazil. This disease carries significant rates of lethality and morbidity, leaving sequelae such as deafness, seizures, paralysis, and mental disability. Considering these factors and given that the population under 5 years old is the most affected, in 2010 the conjugated meningococcal C vaccine was included in the National Immunization Program, being applied at 3 and 5 months, with a booster between 12 and 15 months of age. In 2017, vaccination of adolescents aged 12 to 13 years was introduced and, in 2018, it was extended to individuals aged 11 to 14 years. Therefore, it is important to clarify the relationship between vaccination coverage and the number of deaths by meningococcal infection in recent years. **Objective:** To associate meningococcal C vaccination with the number of deaths by meningococcal infection in the Brazilian child and adolescent population, considering the period from 2010 to 2022. **Methods:** This is a cross-sectional, descriptive, and retrospective epidemiological study conducted through the analysis of data made available by the DATASUS health information database, from 2010 to 2022, selecting individuals up to 19 years of age. **Results:** The total number of deaths from meningococcal infection among individuals up to 19 years old in this period was 1,801, with approximately 52.42% of these deaths occurring in children under 4 years old. The year 2010 had the highest number of deaths from meningococcal infection, corresponding to about 18.6% of the total, and between 2010 and 2022 there was an 87.46% reduction in the number of deaths. Between 2019 and 2021, the number of deaths was reduced by 69.9%, however in 2022 this number started to increase, totaling 11 more deaths than in 2021. The number of meningitis cases, considering the same population and the same period, followed the increases and decreases in the number of deaths by meningococcal infection. **Conclusion:** According to the data analyzed, it can be inferred that, after the introduction of the conjugated meningococcal C vaccine, there was a reduction in the number of deaths from meningococcal infection and confirmed cases of meningitis. However, although the infant population is the main target of vaccination, it still represents the highest death rate. In addition, in the years most affected by the COVID-19 pandemic, there was a decrease in the number of deaths from meningococcal infection in all age groups, which may be associated with social isolation and the probable underreporting that occurred during this period. Finally, as meningococcal disease is still a relevant public health problem, especially in children and adolescents, new preventive and immunization actions aimed at this population and the strengthening of epidemiological surveillance are necessary, considering the post-pandemic scenario.

Meningoencephalitis caused by Varicella-zoster virus complicated with cerebral venous thrombosis: presesentation in an imunocompetent patient without previous rash

Gabriel Augusto Wandekoken[1], Clara Moreira Gonzaga[1], Julia de Oliveira Xavier Ramos[1], Carolina Candeias da Silva[1], Enedina Maria Lobato de Oliveira[1], Henrique Ballalai Ferraz[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Gabriel Augusto Wandekoken; Email: gabrielwandekoken@hotmail.com.

Case presentation: A 58-year-old woman with hypertension, type 2 diabetes, dyslipidemia, and childhood epilepsy, was brought to the hospital due to a 12-day history of confusion, inattention, spatial disorientation, and incoherent speech, with an insidious onset and progressive course. Two days before admission, she developed aggressive and hypersexualized behavior, nausea and emesis. Upon admission, she had stable vital signs, no skin lesions, was agitated, disoriented and aphasic. An initial cranial CT scan showed no abnormalities. Lumbar puncture revealed an opening pressure of 43 cmH2O, cerebrospinal fluid (CSF) analysis showed 355 cells/μL (83% lymphocytes), protein of 219 mg/dL and positive PCR for Varicella-zoster virus (VZV), with other microbiological tests negative. An EEG at admission showed lateralized rhythmic delta activity and bilateral frontotemporal epileptiform discharges. Cranial MR angiography revealed cerebral venous thrombosis in the left sigmoid sinus and internal jugular vein. She was treated with intravenous acyclovir for 14 days and enoxaparin 1mg/kg bid, showing clinical and electroencephalographic improvement, and was discharged without sequelae for outpatient follow-up on anticoagulation with direct oral anticoagulant (DOAC). **Discussion:** VZV is a neurotropic herpesvirus. It causes varicella (chicken pox) as a primary infection, after which the virus remains latent in different ganglionic neurons, capable of reactivating during immunosuppression or advanced age. CNS involvement by VZV is uncommon, particularly in immunocompetent population, occurring in both primary infection and reactivation, and can manifest as diffuse encephalitis, acute cerebellar ataxia, myelitis, stroke, polyneuropathy, and aseptic meningitis. Acute diffuse encephalitis more frequently affects adults, presenting with delirium, seizures, and focal neurological signs. The most accurate diagnostic method for viral encephalitis is VZV PCR in CSF. Current data suggest VZV as an emerging cause of encephalitis in young, immunocompetent patients. Although skin lesions are a hallmark of the disease, up to 50% of reported cases of VZV neurological complications occur without cutaneous manifestations. This case features two unusual characteristics of VZV CNS involvement: varicella encephalitis not preceded by a rash, in an immunocompetent patient younger than 60 years. **Final comments:** We describe an atypical case of an immunocompetent patient with acute varicella-zoster meningoencephalitis without preceding rash, complicated by a cerebral thrombotic event. This condition is classically described more frequently in immunosuppressed individuals. However, This case highlights the importance of considering VZV in the differential diagnosis of encephalitis presentations in immunocompetents.

Meningoencephalitis due to free-living amoebae in an immunocompetent patient: case report

Danielli Regina da Silva[1], Laisy Bárbara Souza Silva[1], Airton Sena Oliveira Sales[1], Hágda Pires Moreira Damasceno[1], Giovani Zago Borges[1], Gabriela Adami Ribeiro[1], Giovana Bertin Mira[1], Larissa Batista Xavier[1], Emerson Oliveira Milhorin[1], Mario Leon Silva Vergara[1]

[1]Universidade Federal do Triângulo Mineiro, Uberaba MG, Brazil.

Correspondence: Danielli Regina da Silva; Email: d202011051@uftm.edu.br.

Case presentation: Woman, 67 years old, mixed race and previously healthy. Admitted to the Clinical Hospital with a progressive history of visual blurring, memory changes, unestimated weight loss and paresis in the lower limbs for 2 months. A cranial magnetic resonance imaging was performed, which revealed two expansive corticosubcortical lesions in the left hemisphere, with intense and heterogeneous post-contrast enhancement, partially defined limits, with surrounding vasogenic edema, foci of calcifications and hemosiderin deposits. The initial diagnostic hypothesis proposed was oligodendroglioma. The patient underwent a surgical procedure, during which it was observed that the lesion had an inflammatory/infectious appearance. Pathological examination: no evidence of neoplasia and extensive necrotizing encephalitis with inflammatory infiltrate, xantomized macrophages and rounded, small, eosinophilic structures, with discretely basophilic nuclei suggestive of cysts and free-living amoebae trophozoites. Empirical treatment with metronidazole, trimethoprimsulfamethoxazole and fluconazole was initiated. Miltefosine and albendazole were later added. The patient's neurological condition worsened and 13 days after starting treatment, she died. **Discussion:** Free-living amoebae considered pathogenic to humans are: Naegleria fowleri, Acanthamoeba spp. and Balamuthia mandrillaris. The last two species can affect both immunocompetent

and immunocompromised individuals and are associated with subacute or chronic granulomatous meningoencephalitis with an unfavorable outcome in most cases. Meningoencephalitis caused by free-living amoebas is a rare condition, late diagnosed and lethal in more than 90% of cases, given the unavailability of effective treatment. The regimen prescribed for this patient was based on the suggestion of several authors, but with a very limited level of evidence. The clinical history and chronic evolution of this case, combined with the anatomopathological findings, support the diagnosis of granulomatous amoebic meningoencephalitis caused by Balamuthia mandrillaris. The diagnosis of this condition represents a challenge and is generally performed postmortem and is based on the histopathology of the brain lesion. Defining the amoebae species requires specific molecular, immunohistochemical and serological methods, which are only available in a few places. **Final comments:** Protozoal meningoencephalitis is rare and presents a challenging diagnosis, especially in immunocompetent patients, given its nonspecific clinical presentation. Thus, this report clearly illustrates the difficulties in early diagnosis of meningoencephalitis caused by free-living amoebae and the importance of brain biopsy for diagnostic elucidation.

Metabolic syndrome in patients with Duchenne muscular dystrophy

Marcela Misao Miyata[1], Marcondes Cavalcante França Júnior[1], Mariana Rabelo de Brito[1], Anamarli Nucci[1]

[1]Universidade Estadual de Campinas, Campinas SP, Brazil.

Correspondence: Marcela Misao Miyata; Email: marcelamisao@hotmail.com.

Background: Duchenne muscular dystrophy (DMD) is the most frequent muscle dystrophy in children. It is an X-linked condition caused by loss-of-function variants in the DMD gene. During disease course, affected patients lose lean body mass, become severely motor disabled and are often treated with long term steroids. All these factors pose them at increased risk for developing metabolic syndrome (MS), even as children. Surprisingly, there are few studies addressing this aspect in DMD cohorts, particularly in Brazil. **Objective:** To estimate the frequency and risk factors for DMD-related MS in a Brazilian cohort. **Methods:** This is a cross-sectional study involving 46 patients with DMD regularly followed at Universidade Estadual de Campinas. All subjects underwent detailed clinical (Blood pressure, BMI, Motor function) and laboratorial (Serum glucose, HbA1C, cholesterol and triglyceride levels) evaluation. We also recorded demographic, genetic and steroid use (cumulative dose) data from each subject. MS was defined according to the international federation of diabetes criteria for children/teenagers. In addition to these data, we also measured the volume of each patient hypothalamus and compared it with healthy controls, using the HypAST pipeline developed at Universidade Estadual de Campinas. **Results:** mean age of patients was 11.1 years and there were 60.8% wheelchair bound. Most of them had either DMD deletions (n=26) or duplications (n=5). Four of the patients fulfilled the entire set of criteria for MS. However, particular clinical features of the syndrome were frequently found: obesity in 41.8% and 62.7% of body mass index above percentile 85, central obesity in 65.9% and increased blood pressure in 18.2%. Hb1AC was normal in all individuals and glucose was elevated in one participant. However, age-adjusted increased cholesterol and/or triglyceride levels were noticed in 65.2% of the patients. No significant differences were found when comparing the volumes of the hypothalamus between patients and controls. **Conclusion:** metabolic abnormalities are frequent and should be actively investigated in DMD. The existing MS diagnostic criteria may not be adequate for these patients and contribute to underdiagnosis.

Methodological quality of experimental studies with cannabinoids in Alzheimer's disease: a systematic review.

Maria Eduarda Kobayashi Teixeira[1], Maria Antônia Vianna Santos[1], João Lucas Lima Diogo[1], Ana Clara Costa de Siqueira Campos[1], Ruben Costa Santos Neto[1], Lara Millena Miranda Frota[1], Thiago de Faria Junqueira[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Maria Eduarda Kobayashi Teixeira; Email: mariateixeira20.1@bahiana.edu.br.

Background: Alzheimer's disease (AD) is a progressive neurodegenerative disease that results in a significant decline in cognitive, mnemonic and behavioral functions, leading to chronic impairment of patients' quality of life. However, currently available pharmacological treatments, such as acetylcholinesterase inhibitors (e.g. Rivastigmine) and glutamatergic drugs (e.g. Memantine) - which have been previously validated in experimental models - are still not capable of stopping the functional deficits of the disease. Experimental models, in turn, are crucial for the development and discovery of new therapeutic approaches. Therefore, exploring the differences between experimental and clinical results in the treatment of AD with cannabinoids can clarify and generate new hypotheses, expanding investigations into the medicinal use of this class of substances. **Objective:** To evaluate the methodological quality of experimental studies on Alzheimer's Disease with rodents, which used cannabinoids as a therapeutic intervention. **Methods:** The systematic review followed the guidelines of the PRISMA Protocol. The searches were carried out on the MEDLINE/Pubmed, Scielo and LILACS platforms, using the descriptors ("NAME OF THE EXPERIMENTAL MODEL WITH RODENTS") AND ("CANNABINOIDS"). Information was extracted from the articles about the type of experimental model, the therapeutic intervention with cannabinoids and the assessment of cognitive deficits in rodents. The ARRIVE Protocol was applied to assess methodological quality and the SYRCLE's RoB Tool to check the risk of bias. **Results:** After applying the inclusion and exclusion criteria, five articles were included in the present review: two used 5xFAD transgenic mice and the others used APP/PS1 mice. The article by Wang et. al stood out from the others for being the only one with moderate methodological quality (with the highest score assigned) and low risk of bias, however the main clinical outcome tested was spatial memory, without other cognitive implications. Researchers have applied cognitive tests in water mazes or open spaces and some studies included immunohistochemical analysis of mouse tissues. It was also possible to identify important differences in cannabinoid dosages, which ranged from 0.002 to 10mg/kg. **Conclusion:** The systematic review revealed that the methodological quality of experimental studies with cannabinoids for the treatment of Alzheimer's disease is unsatisfactory. None of the studies analyzed achieved a good assessment in the ARRIVE Protocol and only one was classified as low risk of bias by SYRCLE's ROB. Furthermore, the studies presented significant methodological heterogeneity. Therefore, given the results of this review, the use of cannabinoids to treat Alzheimer's in experimental studies with rodents is still a topic that needs to be explored in the scientific literature.

Metronidazole intoxication. A important differential diagnosis of dizziness and encephalopathy in the elderly: a case report

Rafael Bragança Rodrigues Matias[1], Eduardo Mesquita[1], Ana Luisa Vieira de Faria Donadon[1], Amanda Miranda de Mendonça[1], Alex Araujo Fernandes[1], Matheus Luís Braga Munareto[1], Alex Machado Baeta[1], Hennan Salzedas Teixeira[1], Matheus Alves da Silva[1]

[1]Beneficiência Portuguesa, São Paulo SP, Brazil.

Correspondence: Rafael Braganca Rodrigues Matias; Email: rafaelwaa@gmail.com.

Case presentation: An 87 year old man presented to the hospital for evaluation of a traumatic brain injury due to a fall secondary to the worsening of a previous chronic dizziness and consciousness impairment. He had advanced Alzheimer disease, high grade atrioventricular block, systemic arterial hypertension and chronic pulmonary obstructive disease. He had a diagnosis of pseudomembranous colitis in the last month, and was using oral metronidazole and vancomycin for two weeks before the hospital evaluation. His neurological examination showed bilateral dysmetria and dysdiadochokinesia. Due to the cerebellar features, a magnetic resonance imaging was performed and showed bilateral hypersignal in dentate nucleus, inferior colliculus, subthalamic nucleus and in the splenium of the callosum body, compatible with metronidazole intoxication. He had a neurological improvement after metronidazole suspension. **Discussion:** Metronidazole-induced neurotoxicity is a rare adverse effect that can lead to cerebellar ataxia, dysarthria, and peripheral neuropathy. These symptoms may arise from either short- or long-term metronidazole use. The exact mechanism of neurotoxicity remains unclear, but neuroimaging plays a crucial role in diagnosis. To reach an accurate diagnosis, clinicians should maintain a high clinical suspicion, and sometimes brain help in the differential diagnosis and to identify specific abnormalities. Withdrawing metronidazole promptly is necessary to avoid additional morbidity. Discontinuation of the offending agent is currently the only effective treatment. Early referral to rehabilitation services is essential for optimizing functional outcomes in affected patients. **Conclusion:** This case highlights the importance of a right history when evaluating the elderly, because sometimes, unlike our case, the magnetic resonance imaging may not show the classic abnormalities and the diagnosis may be missed. A good clinical history, with neuroimaging as a complementary exam, is fundamental in theses cases.

https://doi.org/10.5327/CBN241079

Microdeletion syndrome 8q22.2q23.3: a rare case in Brazil.

Beatriz Medeiros Correa[1], Paulo Afonso Ortega[1], Marcio Melegaro[1], Elisangela Melegaro[1], Walter Arayjo[1], Jemerson Silva[1], Maria Fernanda Pontelli[1], Khadige Arabi[1]

[1]Faculdade de Medicina Unoeste, Guarujá SP, Brazil.

Correspondence: Beatriz Medeiros Corrêa; Email: beamedneuro@gmail.com.

Case presentation: This case report describes a pediatric patient referred for evaluation due to Neuropsychomotor Developmental Delay (NPMD) and pondero-statural deficit, resulting from a rare genetic condition due to microdeletion 8q22.2q23.3. **Discussion:** Female patient, was referred to the pediatrics department for evaluation of NPMD and pondero-statural deficit. The gestational history did not reveal significant complications, with normal growth until the last trimester of gestation, when ultrasound identified the presence of diaphragmatic hernia. Born via cesarean section at term (39 weeks), weighing 2570g, with a length of 45cm, head circumference of 33cm, and chest circumference of 31cm. At birth, the patient had respiratory difficulty, requiring immediate ventilatory support and was transferred to the neonatal ICU without further complications. Neuropsychomotor development revealed early signs of hypotonia and delay in motor milestones, standing with support only at 22 months, without

ambulating or babbling words, and delayed dentition with anomalous dental eruption. The patient had an evaluated height of 79 cm (below the 3rd percentile), weight of 8255 g (below the 3rd percentile), head circumference of 45 cm (between the 10th and 25th percentiles), with a broad forehead, hypertelorism, alternating divergent strabismus, short palpebral fissures with epicantus, global hypotonia, preserved muscular strength, and severe intellectual deficit. Complementary exams revealed, Blood karyotype (20 cells): 46, XX, t(7;8) (p15;q22) - presence of apparently balanced translocation involving chromosomes 7 and 8; SNP-Array: presence of chromosomal deletion 8q22.2q23.3 and duplication 15q26.3; Urinary screening for inborn errors of metabolism: within normal limits; TSH: within normal limits. **Final comments:** Clinical examination associated with complementary exams indicated a diagnosis of chromosomopathy due to chromosomal deletion 8q22.2q23.3. A review of the phenotype-genotype correlation of 8q22.2-q23.3 was seen in seven other cases in the literature showing presence of cleft palate or facial, abnormal intrauterine growth, epilepsy, trichorhinophalangeal syndrome, cryptorchidism or micropenis which differ from the presented clinical picture. Parental exams did not reveal the presence of 8q microdeletion, indicating a low risk of recurrence for future pregnancies. There is no specific treatment for this condition, but rehabilitation is a valuable tool for the development of affected children.

https://doi.org/10.5327/CBN241080

Migraine and other headache syndromes in Brazil: an epidemiological analysis over the last 5 years

Caroline Patrícia Amaral Costa[1], Matheus Prado dos Santos[2], Fernando Silva Galvão[1], Daniel Lucas Araujo Ramos[1], Rafael Hendrick Freitas de Paula[2], Luan Nascimento Pereira de Amorim[2]

[1]Universidade Federal do Pará, Belém PA, Brazil.
[2]Universidade do Estado do Pará, Belém PA, Brazil.

Correspondence: Caroline Patrícia Amaral Costa; Email: caroline.costa@ics.ufpa.br.

Background: Migraine is one of the most common neurological conditions in the population, significantly impacting the quality of life of those affected. In Brazil, the types of headache syndromes vary epidemiologically, affecting health policies and resource allocation. Understanding the epidemiological differences between regions to identify distribution profiles is essential for developing strategies to control the current scenario of headache syndromes in the country. **Objective:** To analyze the epidemiological profile of patients affected by migraine and other headache syndromes in Brazil between 2019 and 2023. **Methods:** This is an ecological, cross-sectional, and descriptive study with a quantitative approach, based on secondary data from the Department of Informatics of the Unified Health System (DATASUS), recorded from 2019 to 2023 in Brazil. The following variables were analyzed: region, deaths per year, mortality rate, gender, ethnicity, and age group. **Results:** In 2019, there were 11,996 hospitalizations, decreasing to 8,778 in 2020 and 8,505 in 2021. They then increased to 10,293 in 2022 and 11,697 in 2023, totaling 51,269 over the period. The Northeast led with 15,864 hospitalizations, followed by the Southeast (14,946). The most affected age group was 30-39 years old (9,295). In the Northeast, hospitalizations were concentrated in the 30-39 age group (2,898). In the Southeast, the 30-39 age group was prominent (2,866). In the South, there was a peak in the 30-39 age group (2,249). Hospitalizations were predominantly among women, with a total of 33,584 cases, compared to 17,685 cases in men. Black individuals led with 22,600 hospitalizations, followed by whites with 19,398. Regarding deaths, there were 79 in 2019, rising to 71 in 2020 and 113 in 2021, stabilizing at 112 in both 2022 and 2023, totaling 487 deaths. The Northeast region recorded the highest number of deaths during the period (257). The average mortality rate was 0.95. The majority of deaths occurred among individuals aged 60-69. In the Northeast, deaths predominantly occurred among black individuals, with 204 cases. In the Southeast, the majority were white, with 24 cases, and in the South, whites predominated, with 33 deaths. In the North, there were 113 deaths among black individuals, and in the Midwest, there were 6 deaths. **Conclusion:** The study concludes that there was significant variation in the number of hospitalizations during the observed period, while the number of deaths increased steadily over the last two years. Additionally, the Northeast region accounted for the majority of hospitalizations and deaths resulting from the condition. In terms of race, black individuals led in the number of hospitalizations and deaths, and in terms of gender, females were the most affected. These data highlight the need for policies aimed at the treatment and prophylaxis of migraines and other headaches, especially in the Northeast.

Migraine with aura and paradoxical embolism: case report

Assis Porfirio Furtado Nogueira[1], Tulio Marlus Castro Lucena[1], Vitor Gustavo Souto Leão[2], Mariana Cota Bastos[2], Renato Maciel Freire de Paula e Silva[3], Letícia Januzi de Almeida Rocha[2], Maria Júlia Tabosa de Carvalho Galvão[2], Geovane Brito Affonso[2], Érika Santos Machado[1], Alden Rodrigues de Albuquerque[1]

[1]Hospital Geral de Alagoas, Maceió AL, Brazil.
[2]Universidade Federal de Alagoas, Maceió AL, Brazil.
[3]Hospital Universitário Oswaldo Cruz Recife PE, Brazil.

Correspondence: Túlio Marlus Castro Lucena; Email: tuliomarlus.neuro@gmail.com.

Case presentation: A 29-year-old female patient, a smoker (1 pack/day) with a history of migraine with visual aura since the age of 15, was admitted to an emergency service with a sudden onset of dysarthria and facial asymmetry associated with intense headache, followed within a few hours by complete right-sided hemiparesis. She was admitted with 11 points on the NIHSS (National Institute of Health Stroke Scale) and underwent a cranial Computed Tomography (CT) scan, which revealed hypodense lesions in the right frontal, insular, and nucleocapsular regions, suggesting an acute ischemic event. Cranial CT angiography identified areas of narrowing and luminal irregularities in the M2 branch of the left middle cerebral artery. Further etiological investigation for ischemic stroke (IS) in a young patient included: Carotid and Vertebral Doppler (CVD) without evidence of stenosis; Transthoracic Echocardiogram showing regular rhythm, normal left atrial volume, 61% ejection fraction, and the presence of an aneurysmal interatrial septum; and Transcranial Doppler with microbubble test revealing the presence of a right-to-left shunt. The patient is awaiting scheduling for a transesophageal echocardiogram and 24-hour Holter monitoring. She remains on prophylaxis with Aspirin 100 mg and Simvastatin 40 mg. **Discussion:** Stroke is one of the leading causes of death and acquired disability worldwide. Brazil has the fourth highest mortality rate from this condition among Latin American countries, with an incidence of 150 cases per 100,000 inhabitants. Migraine with aura is a well-established risk factor for ischemic stroke and constitutes an important differential diagnosis in emergency settings. The exact pathophysiological mechanism for this association remains uncertain, but the main hypotheses include oligemia, vasospasm, endothelial dysfunction, genetic predisposition, paradoxical embolism, among others. Some meta-analyses have found that people with migraine with aura have approximately double the risk of having a stroke compared to those without migraine or those with migraine without aura. Some studies reaffirm this association and highlight that the risk is particularly high in young women, especially those who smoke or use oral contraceptives, as well as its association with right-to-left cardiac shunts, a finding commonly related to patent foramen ovale (PFO). **Final comments:** The association between migraine with aura and ischemic stroke should be commonly addressed among healthcare professionals and the general public. The described case supports these findings and reinforces the importance of this type of headache as an established risk factor for cerebral ischemia, as well as highlighting the relevance of PFO research in this group.

Multiple sclerosis (MS) is the most common demyelinating disorder, and typically manifests at a highly productive period of life. Common findings among patients is progressive fatigue and cognitive function impairment, severely impacting quality of life and economic burden of disease. MS cognitive impact on several domains, mainly information processing speed and learning disability, differ from the patterns present in dementias such as Alzheimer, though clinical presentation of both syndromes may overlap at later stages of MS. While studies have been carried out on older patients (above 50 years), no study was found focusing on younger populations and the transitional stage between normal cognition and Alzheimer, denominated mild cognitive impairment (MCI). The study's objective is to evaluate the risk of a patient below 50 years receiving an MCI diagnosis within 10 years of a MS diagnosis in a Brazilian population. An electronic medical record aggregator called TriNetX was used to anonymously obtain the patient data used in the study, using exclusively hospital related records. The Brazilian cohort was built using a Brazilian-only database via selecting patients who received the MS diagnosis in the last 10 years time frame, had never received an MCI or MS diagnosis before, and have less than 50 years. The MS diagnosis was considered the index event, while the outcome was a MCI diagnosis within 10 years of the index event. Risk was obtained by calculating the fraction of patients with the selected outcome from the cohort's total. Test results were a cohort of N=2,220, of whom 10 patients had the selected outcome, with a risk of 0.45% in 10 years. The mean age of the cohort was 37 years, with standard deviation of 8 years and median follow-up was 455 days. While some studies in older age groups suggest a higher cognitive impairment and risk of dementia in later stages of MS, the data gathered in the study shows a low risk of MCI in young patients with MS, specially when compared to the expected 30 to 70% of cognitive impairment in early stages of the disease. Rather, this dual pattern of cognitive disturbances may corroborate a shift over time in the underlying pathology of the cognitive impairment.

Miller Fischer syndrome post dengue fever: a case report

Isabela da Costa Rodrigues[1], Matheus Zago[1], Ivo Marcos Darella Lorenzin Fernandes Neto[2], Eduarda Basso Badalotti[2], Angelo Marcelo Wosniacki Filho[2], Gabriel Angelo Garute Zenatti[2], Renato Endler Iachinski[2], Antonio Carlos de Andrade Soares[2]

[1]Centro Universitário Fundação Assis Gurgacz, Cascavel PR, Brazil.
[2]Fundação Hospitalar São Lucas, Cascavel PR, Brazil.

Correspondence: Isabela da Costa Rodrigues; Email: isacostarod.2001@gmail.com.

Case presentation: Female, 29 years old, manifesting ascending and progressive paraparesis on lower limbs, starting on feet, evolving with paresthesia, paresis and paresthesia on upper limbs, peripheral facial paralysis on the right and transfer dysphagia. The patient was diagnosed with dengue fever 2 weeks before the onset of symptoms. Physical examination: peripheral facial paralysis on the right, tetraparesis (4-/5) and symmetrical global hyporeflexia. Skull CT with no alterations and lumbar puncture revealed hyperproteinorrachia with protein-cytological dissociation on CFS, suggesting Guillain-Barré syndrome. Terefore, 25 vials of immunoglobulin, 5g/vial, were started for 5 days. During hospitalization, the patient developed bilateral peripheral facial paralysis. After finishing the immunoglobulin infusion, there was partial improvement in paraparesis (4+/5) and facial diplegia. **Discussion:** Miller Fisher syndrome (MFS), considered a multifocal neuropathy, presents with the triad: ataxia, ophthalmoplegia and areflexia. However, there are many clinical variations for this pathology, with involvement of the facial nerve being the most common. This syndrome is a benign variant of Guillain-Barré syndrome (GBS), generally associated with previous gastrointestinal or respiratory tract infections and presenting proteino-cytological dissociation in the cerebrospinal fluid as the diagnostic criterion. There are some reports in the literature about the association of GBS and MFS with arboviruses such as Dengue and Chikungunya, especially in epidemic regions. This disease is treated in the same way as GBS, with intravenous immunoglobulin (IVIg) or, alternatively, plasmapheresis. As it is a benign condition, patients generally progress well after treatment, with complications or sequelae of the disease being rare. **Final comments:** Being a rare variant of GBS, MFS usually appears after gastrointestinal or respiratory tract infections. The case discussed demonstrates the emergence of MFS after infection with an arbovirus very common in tropical regions, Dengue. As this is a rare association, there are few similar reports in the literature with bilateral peripheral facial paralysis associated. Therefore, it is essential to record them when they arise.

Miller-Fisher syndrome: a case report

Maria Carolina Marçon Barroso[1], Laura Alonso Matheus Montouro[1], Cibele Alexandra Ferro[1], Guilherme Guimarães Coelho[1], Thaís Delamagna Bordonal[1], Marcus Vinicius Rodrigues de Mello Junior[1], Juliana Arantes Calil[1], Marina de Carvalho Bofo[1]

[1]Faculdade de Medicina de Catanduva, Catanduva SP, Brazil.

Correspondence: Maria Carolina Marçon Barroso; Email: barrosomariacarolina@gmail.com.

Case presentation: A 35-year-old male patient admitted to the emergency department due to symmetrical flaccid paraparesis, hypo/arreflexia, symmetrical and ascending after a history of airway infection, as well as ophthalmoplegia, ataxia and generalized arreflexia. On physical examination, he presented with symmetrical flaccid tetraparesis, worse in the lower limbs, global areflexia and dysphonia, associated with cerebelar symptoms. CSF was collected and showed slight protein-cytological dissociation. During hospitalization, immunoglobulin was indicated and then was a progressive clinical improvement. Even without an antibody test, the diagnosis was Miller-Fisher Syndrome, due to the clinical presentation and the improvement after immunoglobulin. **Discussion:** Miller-Fisher syndrome (MFS) is a variant of Guillain-Barré syndrome (GBS), an acute autoimmune inflammatory demyelinating polyradiculopathy. This variant is characterized by at least 2 of this classic triad: ataxia, ophthalmoplegia and areflexia. The pathophysiology involves autoimmune mechanisms that can be triggered by external factors, such as respiratory or gastrointestinal infections, by attack to gangliosides. The presence of IgG anti-GQ1b antiganglioside antibodies in the acute phase of the disease is a marker of MFS, but its value decreases with the duration of the disease. Just as the distribution of GQ1b is not homogeneous. Both factors can explain the seronegativity of 10 to 30% of cases. The Brighton criteria uses clinical history, physical examination, laboratory and neuroimaging for diagnosis and does not include this antibody. In the case described, the characteristic clinical picture of the disease, albuminocytological dissociation in the CSF, normal brain and spine MRI allowed the diagnosis. Anti-GQ1b antibody test is unavailable at the service. It is important to highlight that investigation through anti-GQ1b antibody research may be useful in suspected cases of Miller-Fisher syndrome with atypical evolution or unusual clinical manifestations, given that it is a disease that can be treated with the use of plasmapheresis and/or human immunoglobulin. Therefore, the possibility of including the anti-GQ1b antibody test in the tests offered by the Brazilian public health system for selected cases should be considered and evaluated, improving the prognosis and lowering the long-term cost for the system. **Final comments:** The diagnosis of typical MFS is made based on clinical findings associated with CSF analysis and exclusion of other probable causes. The dosage of Anti-GQ1b should be reserved for atypical cases and the incorporation of this diagnostic tool into the Brazilian public health system for these cases should be discussed.

Minimally invasive treatment of intraventricular hemorrhage

Marco Antônio Delazeri[1], Eduarda Rosa Fernandes[1], Giuseppe Dick Bonato[1], Carollina Danezi Felin[1], Carolina Heck Haubrich[1], William Alves Martins[1], Eliseu Paglioli[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Marco Antônio Delazeri; Email: marco.delazeri@outlook.com.

Case presentation: A 77 year-old female is brought to the emergency unit due to left hemiparesis and hemispacial neglect. Previous medical history include hypothyroidism, cardiac arrhythmia and arterial hypertension, and she was regularly taking edoxaban, metoprolol, amlodipine and methimazole. Her symptoms started 3 hours before admission and she had no history of traumatic injury. A brain computed tomography promptly showed extensive right thalamic hematoma associated with vasogenic edema and loss of telencephalic sulci-gyri differentiation, as well as extensive right lateral, third and fourth ventricle hemorrhage and subdural bleeding. There was mass effect leading to lateral ventriculus compression and 0.7 midline deviation, besides hydrocephalus and intracranial hypertension signs. Angiography showed no aneurysm, arterial occlusion or venous thrombosis. At first it was opted for conservative intensive care, and during the following hours she began to show profuse vomits and severe consciousness impairment (Glasgow Coma Scale of 3), undergoing intubation. New computered tomography showed a total bleeding volume increase. The three following days, imaging showed no signs of new bleeding and she had no awakening despite sedatives discontinuation. Continuous electroencephalographic monitoring showed six epileptic episodes beginning at left frontocentral region, during which it was evident right hand automatisms and tonic posturing. Seizures were controlled with levetiracetam, clobazam and phenytoin. Due to no bleeding absorption evidence and lack of consciousness improvement despite anti-epileptic treatment, she underwent external ventriculostomy, with hematoma drainage associated with intraventricular alteplase infusion (4mg three times a day for 3 days). She began to recover consciousness as hematoma and intraventricular hemorrhage resolved. Nowadays, after 4 years of the procedure, she still presents thalamic pain, left hemiparesis and major depression. **Discussion:** A role of minimally invasive surgery has demonstrated significant benefits, sometimes even superior depending on the type of intracerebral hemorrhage: hematoma volume, lobar or ganglionic location, time from hospital arrival to procedure, midline shift, vasogenic edema, and hemoventricle, among others. The standard procedure involves placing an external ventricular catheter guided by CT scan, clot aspiration, and, if necessary, infusion of thrombolytics for clot dissolution. Thrombolytics used mostly include alteplase (rtPA) and urokinase (uPA). The major complication is aspiration with immediate risk of rebleeding. **Final comments:** We present a case in which consciousness impairment had potentially multiple hemorrhagic causes and only resolved after invasive treatment. Minimally invasive neurosurgical procedures in similar cases are not standard practice, although they show potential to help bleeding resolution and quicken recovery, while diminishing long-term sequelae.

Misdiagnosis in multiple sclerosis (MS): the influence of the first doctor's specialty at the disease onset

Nara Samara Silva dos Santos[1], Alex de Cerqueira Silveira Figueiredo[1], Gabriel Souza Medrado Nunes[1], Maria Eduarda Messias Vassoler[1], Milena Fernandes de Oliveira[1], Júlia Xavier Oliveira[1], Luana Araujo Passos[1], Caio Fontes do Nascimento[1], Bruno Bacellar Pedreira[2], Pedro Antonio Pereira de Jesus[2]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.
[2]Universidade Federal da Bahia, Hospital Universitário Professor Edgard Santos, Salvador BA, Brazil.

Correspondence: Nara Samara Silva dos Santos; Email: nara.samara@ufba.br.

Background: Multiple sclerosis (MS) is a chronic autoimmune condition that affects the central nervous system with variable clinical presentation both in terms of neurological functions affected and the intensity of disability generated. These characteristics create a barrier that leads to difficulty in recognizing, suspecting, and confirming the diagnosis of MS, resulting in misdiagnosis, a common and potentially dangerous condition, as it delays the start of disease-modifying therapies and increases the possibility of worse outcomes. **Objective:** To investigate the relation between misdiagnosis and the first doctor's specialty at disease onset in MS patients. **Methods:** This cross-sectional study was conducted with patients diagnosed with MS according to the McDonald criteria, from July/2021 to May/2024. Clinical and demographic data were collected through interviews in a reference center in Bahia, Brazil. Binary logistic regression was used to identify the association between misdiagnosis and the first doctor's specialty. We adjusted the model for other variables such as ethnicity, comorbidities, region of residence and cranial nerve alterations, and motor and sensitive symptoms at onset. **Results:** A total of 313 individuals were selected, of whom 216 (69.0%) were female. The median age at disease onset was 31 (22-39) and at admission to the study was 40 (30-48). Of the patients analyzed, 113 (36.1%)

received an alternative diagnosis before MS; of these, 86 (76.1%) had a non-neurologist as their first doctor while of those without misdiagnosis (200), 122 (61.0%) went to a non-neurologist (p=0.009). Regarding past misdiagnosis, the most prevalent were stroke (21.2%) and labyrinthitis (19,5%); other atypical and less prevalent alternative diagnoses were depression, stress, and flu. In the adjusted model analysis, the specialty of the first doctor as a non-neurologist (OR 1.98 [95% CI 1.14-3.42]) was the factor related to the presence of erroneous previous diagnoses (p=0.015), while ethnicity of African descent (OR 0.49 [95% CI 0.27-0.86]) was associated to less misdiagnosis (p=0.014). **Conclusion:** Misdiagnosis remains an important barrier in the patient's journey to the definitive MS diagnosis in our population. Most of the patients who received previous alternative diagnoses looked for a non-neurologist as their first doctor and this factor could be associated with misdiagnosis in MS. These results highlight a possible worrying gap in knowledge about the presentations of this disease and the importance of addressing it during medical education, especially given the increasing global prevalence of MS.

Mitochondrial neurogastrointestinal encephalomyopathy (MNGIE) - like syndrome associated with polg gene mutations: a case report

Rhanice Soares Huguenin Câmara[1], Roberto Pereira Santos[1], Filipi Brito[1], Ana Carolina Leite[1], Barbara Pina Aiello[1], Matheus Jorand Cecatto[1], Amanda de Morais Affonso[1], Caio Tardin[1], Victor Evangelista Rodrigues Pereira[1], Marcos Raimundo Gomes de Freitas[1]

[1]Universidade Federal do Rio de Janeirotal, Hospital Universitário Clementino Fraga Filho, Serviço de Neurologia, Rio de Janeiro RJ, Brazil.

Correspondence: Roberto Pereira Santos; Email: r.santos.ufrj@gmail.com.

Case presentation: Mitochondrial neurogastrointestinal encephalomyopathy (MNGIE) arises from mutations in the gene encoding thymidine phosphorylase (TP), a mitochondrial enzyme. This case involves a 55-year-old woman with lifelong gastrointestinal issues, including abdominal pain, intestinal obstruction, nausea, dysphagia, early satiety, and vomiting. Concurrently, she developed progressive muscular weakness, eventually leading to inability to walk independently. Despite extensive medical consultations and investigations spanning 55 years, no definitive diagnosis was reached. Physical examination revealed intolerance to walking, proximal weakness in all limbs with predominant proximal involvement, generalized areflexia, and distal hypoesthesia across all sensory modalities. Her parents were not consanguineous, and her sibling reported a similar but asymptomatic condition. The clinical presentation aligned with MNGIE syndrome criteria (Hirano, 2021). Exome sequencing identified a pathogenic variant in the POLG gene, c.752C>T (p.Thr251Ile), and a variant of uncertain significance, c.752C>T (p.Pro587Leu), confirming MNGIE syndrome with a novel association with POLG mutation. **Discussion:** MNGIE results from mutations in the TYMP gene, impairing TP function and causing thymidine (dThd) and deoxyuridine (dUrd) accumulation, leading to mitochondrial DNA (mtDNA) abnormalities. Onset typically occurs around 17.9 years, with gastrointestinal symptoms manifesting early and progressing to severe complications like diverticulosis, diverticulitis, and hepatopathy. Neurological symptoms include ocular signs, polyneuropathy, hearing loss, and leucoencephalopathy, with cognitive impairment in some cases. The disease is progressive, with a median survival of 35-37 years, primarily due to GI and liver complications exacerbated by cachexia. **Final comments:** This case suggests a novel MNGIE-like phenotype associated with a POLG gene mutation, highlighting the complexity and diversity of mitochondrial disorders. Further research is crucial to elucidate the underlying mechanisms and refine diagnostic and therapeutic strategies for such rare genetic conditions.

https://doi.org/10.5327/CBN241088

Modeling dendritic integration with non-linear dynamics and eigenmodes

Jose Reynaldo Walther de Almeida[1], Thalles Olivi de Almeida[2]

[1]Instituto de Neurociencias de Araraquara, Araraquara SP, Brazil.
[2]Hospital Sirio Libanes, São Paulo SP, Brazil.

Correspondence: Thalles Olivi de Almeida; Email: almeida.thalles@outlook.com.

Background: Dendritic integration is crucial in neuronal function, where excitatory and inhibitory signals are non-linearly summed to determine the generation of an action potential. Besides synaptic interactions, external electric fields also modulate neuronal activity. This study presents an extended differential equation that includes eigenmodes, providing detailed modeling of dendritic integration. **Objectives:** Develop and test a differential equation that predicts the generation or inhibition of action potentials in the axon, considering non-linearity and the effects of electric fields and eigenmodes under different stimulus conditions. **Methods:** The differential equation used is: CmdVmdt=−[gNa(Vm−ENa)+gK(Vm−EK)+gCa(Vm−ECa)]+∑igsyn,i(Vm−Esyn,i)+ extVm+α(Iion·Isyn)+βIext1+e−VmC_m frac{dV_m}{dt} = -left[g_{Na}(V_m - E_{Na}) + g_{K}(V_m - E_{K}) + g_{Ca}(V_m - E_{Ca}) ight] + sum_{i} g_{syn,i}(V_m - E_{syn,i}) + epsilon_{ext} V_m + alpha (I_{ion} cdot I_{syn}) + eta frac{I_{ext}}{1 + e^{-V_m}} CmdtdVm=−[gNa(Vm−ENa)+gK(Vm−EK)+gCa(Vm−ECa)]+∑igsyn,i(Vm−Esyn,i)+ extVm+α(Iion·Isyn)+β1+e−VmIext The equation was numerically solved using the Euler method. Three conditions were simulated: increased excitatory synaptic conductance, increased inhibitory synaptic conductance, and increased influence of external electric fields. **Results:** Simulations under three distinct conditions showed the following findings: 1. Excitatory Synaptic Conductance: A moderate increase resulted in a rapid and pronounced depolarization, bringing the membrane potential closer to the firing threshold but still sub-threshold. 2. Inhibitory Synaptic Conductance: Increased inhibition caused continuous hyperpolarization, moving the membrane potential away from the firing threshold and stabilizing the cell. 3. External Electric Fields: Enhanced influence of electric fields provided moderate depolarization, indicating that while electric fields have significant influence, it is still controlled and insufficient to trigger an action potential. **Conclusion:** The results demonstrate that membrane potential depolarization is strongly influenced by changes in stimulus parameters. The inclusion of eigenmodes in the differential equation provides detailed and precise modeling of dendritic integration. Simulations showed how different stimulus conditions affect membrane potential depolarization. These results help better understand neuronal excitability modulation and open avenues for practical applications in theoretical neuroscience, including memory studies, synaptopathies, and other areas.

Modifiable risk factors in dementia: literature review

Kathleen Torres Tenorio Monteiro[1], Maria Lucia Veluttini Pimentel[1], Ricardo Novis[1], Leticia Fezer[1], Filipe Freitas[1], Raquel Molina Costa[1], Barbara Sampaio de Souza Dias[1], Rodrigo Moreira Pereira[1], Gabriel Rivadavia[1], Cicera Simplicio Machado Leandro[1]

[1]Santa Casa de Misericórdia do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Kathleen Torres Tenório Monteiro; Email: kathleen_tenorio@hotmail.com.

Background: Dementia is a general term used to describe a group of conditions that affect brain function through neuronal loss, leading to a progressive decline in memory, thinking, behavior and the ability to perform daily activities. In the world, around 57 million people live with dementia, and this number is expected to increase to 153 million by 2050 due to global aging, increasing especially in low- and middle-income countries, where the predicted increase in the number of cases is greater. due to the low sociodemographic index. The risk of developing cognitive decline is influenced by a combination of genetic and environmental factors. Although some risk factors that negatively influence cognitive reserve cannot be modified, such as age and genetic predisposition; identifying and addressing modifiable risk factors can help reduce the likelihood of developing dementia or slow its progressain. **Methods:** Systematic review based on applied research in the Pubmed, LILACS, Scielo and Uptodate databases. We selected 203 articles, of which 34 articles were included in this study. The inclusion criteria were articles published and indexed in the aforementioned databases from 2013 to nowaday that addressed the relationship between dementia and modifiable risk factors, in patients who started with cognitive impairment. **Results:** Modifiable risk factors are responsible for around 40% of dementias worldwide, which could theoretically be avoided or delayed. Adopting a healthy lifestyle, with a balanced diet, regular physical activity and control of chronic diseases, is essential in preventing dementia. **Conclusion:** Prevention has to do with public politics through individually adapted health programs and population-based strategies. People in good physical health can sustain a greater burden of neuropathology without experiencing cognitive impairment. It is important to investigate factors that may be protective and delay its development.

https://doi.org/10.5327/CBN241090

Möebius-Polland syndrome associated to epilepsy

Caroline Schiochet Verza[1], David Guillermo Carriazo Galindo[1], Lucas Porcello Schilling[1], William Alves Martins[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Caroline Schiochet Verza; Email: carolinesverza@gmail.com.

Case presentation: A 24-year-old male presented to our epilepsy clinic with recurrent spells of loss of conscience. Past medical history revealed a diagnosis of Möebius syndrome, developmental delay, mild cognitive impairment and recurrent suicidal thoughts. Seizures had begun at 8 eight years-old and never remised. Semiology was diverse and multiple seizure types were suspected, including dyscognitive spells, tonic upper limps seizures and tonic-clonic seizures. Neurological examination revealed bilateral facial and VI nerve palsies, along with right great pectoralis atrophy and tonge fasciculations. At this moment, we initiated valproic acid up to 1500mg a day. This was followed by a significant improvement in seizure rate. Brain MRI demonstrated a right hippocampal atrophy associated to straightening of floor of the 4th ventricule and loss of facial colliculus bilaterally. Electroencephalogram sowed only diffuse disorganization. A further increase in valproic acid rendered seizure-free. **Discussion:** Möebius syndrome is a congenital

disorder characterized by total or partial absence of VI and VII cranial nuclei, leading to an 'expressionless' face and horizontal gaze paralysis. It is estimated to occur 1 in every 100.000 births. This disorder may be caused by several different etiologies, including some medications and congenital infections. About to 90% of patients present normal neurodevelopment, and most of disease symptoms are present at birth. However, rarely it may be associated to other features. Here, we present a case of Möebius-Polland syndrome associated to focal epilepsy. Rarely, other nerves may be affected, such as our patients, including hypoglossal, accessory and even absent of pectoralis major muscle, syndactyly, barchydactyly and hypoplasia of the hand – which added to facial palsy comprise the Möebius-Polland syndrome, seen in our patient. There are only two cases of Möebius syndrome associated to epilepsy, one of which was diagnosed as a psychogenic non-epileptic seizures (PNES) due to the stress of coping with such a devastating congenital illness. MRI findings are a reflection of a hypoplastic brainstem, with loss of VII nuclei and consequently the facial colliculus, leading to a straight 4th ventricule floor. Other findings may include calcification of the pons and absence or cerebellar hypoplasia. This fascinating disorder has many physiopatological theories, but the most accepted is an early ischemic brainstem lesion, causing underdevelopment of cranial nuclei. **Final comments:** Epilepsy and Mobius syndrome is extremely rare, but this association should be kept in mind when dealing with this rare syndrome.

MOGAD optic neuritis possibly triggered by bartonellosis: a case report

Weverton Carlos da Silva Teixeira[1], Aline Paredes Cardoso Fukuda[1], Julia Haddad Labello[1], Mário Luiz Ribeiro Monteiro[1], Leandro Tavares Lucato[1], Guilherme Diogo Silva[1], Tarso Adoni[1], Samira Luisa Apóstolos Pereira[1], Luiz Henrique Martins Castro[1], Dagoberto Callegaro[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Weverton Carlos da Silva Teixeira; Email: weverton.teixeira@hc.fm.usp.br.

Case presentation: A 31-year-old woman presented with fever, malaise, and headache three days after hiking at night in Minas Gerais, Brazil. Five days later, she developed acute visual impairment and pain with eye movements in the left eye (OS). Neuro-ophthalmological evaluation showed 20/70 visual acuity, altered color vision, central scotoma, relative afferent pupillary defect, and mild optic disc hyperemic edema OS, but no other ocular findings. Initial laboratory screening for infections, including syphilis, and CSF analysis were normal. MRI showed signs of optic neuritis (ON) in the intraorbital segment of the left optic nerve, while brain and spine MRI were normal. Treatment with methylprednisolone 1g for three days led to complete visual improvement, followed by rapid corticosteroid tapering. Three weeks later, she presented with a right-sided headache, vision loss, and painful eye movements in the right eye (OD). Visual acuity was 20/800 OD and 20/25 OS. OCT showed bilateral loss of ganglion cells in the macula without other retinal abnormalities. New CSF analysis showed only mild lymphocytic pleocytosis (8 cells). MRI indicated residual alterations in the left optic nerve and acute signs of ON in the entire orbital segment of the right optic nerve. Laboratory evaluation revealed high titers of serum anti-myelin oligodendrocyte glycoprotein (MOG) IgG (1:320) detected by cell-based assay and anti-Bartonella IgG (1:256). Serum anti-AQP4 IgG and CSF PCR for Bartonella henselae were negative. Therefore, treatment included doxycycline 100 mg twice daily for five weeks, methylprednisolone 1g for five days followed by prednisone 60 mg daily, and five sessions of plasmapheresis, resulting in complete visual recovery within two weeks. Anti-Bartonella IgG titers decreased to 1:128 and 1:64 at two and four months, respectively. Gradual corticosteroid tapering has been ongoing for six months. **Discussion:** Myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) has been linked to various infectious triggers, including EBV, CMV, Borrelia burgdorferi, and SARS-CoV-2. B. henselae infection, although more commonly associated with neuroretinitis, emerged as a potential trigger in this case. After a presumed flea bite, initial febrile disease and high serological titers strongly indicated active or recent infection. In contrast, the absence of other ocular abnormalities and a negative CSF PCR for B. henselae reduce the likelihood of direct optic nerve infection. The presence of a core clinical demyelinating event and a clear positive anti-MOG IgG test meet the 2023 MOGAD diagnostic criteria. Longitudinal extensive bilateral ON and the initial response to high-dose glucocorticoids further support the diagnosis of MOGAD. **Final comments:** This case raises the hypothesis that Bartonella infection can lead to optic neuritis not only through direct infection (neuroretinitis) but also as a trigger for MOGAD, an immune-mediated disease.

MOGAD rhombencephalitis and myelitis: a rare report of a lethal case

Larissa Silva Teixeira[1], Ana Flavia Souza Freire da Silva[1], Artur Pedreira de Andrade Souza[1]

[1]Hospital da Bahia, Salvador BA, Brazil.

Correspondence: Larissa Silva Teixeira; Email: dralarissa.neurologia@gmail.com.

We present a case of a 32-year-old brown man, cocaine user, who in November 2023 presented with paraparesis and urinary retention that lasted 7 days. Neuraxial MRI showed an extensive area of hypersignal in the pons tegmentum and middle cerebellar peduncles, in addition to longitudinally extensive signal changes affecting the cervicothoracic spinal cord. CSF showed lymphomonocytic pleocytosis (15 cells), and extensive infectious screening was unremarkable. The patient underwent methylprednisolone (MP) 1g for 3 days, with almost full recovery, including regaining the ability to walk. After 5 days, the patient worsened again, this time with tetraparesis, facial diparesis, dysphagia and dysautonomia. A new MRI showed an increase in the extent of hypersignal areas on T2/FLAIR that compromise the brainstem, in addition to a longitudinally extensive myelitis from the bulbomedullary transition to the conus medullaris. At this time, CSF showed pleocytosis of 60 cells. Molecular viral panel, PCR for tuberculosis, HIV and syphilis serology, schistosomiasis and listeria tests, rheumatological markers and anti-aquaporin antibody were negative. Anti MOG antibody come up positive 1:40. A 7-day course of pulse therapy with methylprednislone and associated therapy with human immunoglobulin was immediately completed, but the patient's dysautonomia worsened, requiring intubation and worsening to cardiorespiratory arrest. After cardiopulmonary resuscitation and numerous complications during hospitalization, such as septic shock and convulsive status after cardiac arrest, the patient progressed with progressive improvement, return of level of consciousness, improvement of tetraparesis, regaining strength up to grade 3. We chose to complete a 2nd cycle of immunoglobulin after 60 days, still during hospital stay, and the patient maintained significant improvement. On the day of hospital discharge, however, he developed septic shock which resulted in death after 10 days. The fact that MOGAD mainly involves the optic nerves and spinal cord involvement in MOGAD often affects the thoracic region and the conus medullaris may contribute to its lower mortality rate. We report a serious case of medullary bulb involvement that resulted in death despite initially have showed a clear improvement after agressive immunotherapy.

MOGAD syndrome: a differential diagnosis between pediatric demyelinating encephalopathies - a case report

Vanderson Carvalho Neri[1], Thaynná Alvim Gomes[2], Ana Carolina Monteiro Malafaia Carvalho[2]

[1]Hospital Federal da Lagoa, Departamento de Neurologia, Rio de Janeiro RJ, Brazil.
[2]Faculdade de Medicina de Campos, Departamento de Neurologia, Campos dos Goytacazes RJ, Brazil.

Correspondence: Vanderson Carvalho Neri; Email: vandersoncn@yahoo.com.br.

Case presentation: Female, mixed race, 12 years old. In February 2020, he developed a sudden onset of aphasia, sialorrhea, and distal paresis of the right upper limb. Skull MRI: large hypersignal lesion on Flair and T2 with bilateral digitiform edema pattern; discrete diffusion hypersignal and areas of contrast enhancement with a pattern of perivascular/perivenular uptake in the subcortical white matter of the frontal regions; optic neuritis on the left and, after 15 days, spontaneous remission of aphasia. After two months, a new skull MRI showed significant improvement in the reported lesions, which no longer captured contrast, but there were new lesions on the right parietal surface and in the right temporo-occipital subcortical white matter. In November 2021, focal convulsive crisis. In 2022, generalized tonic-clonic seizure. She remained asymptomatic until December 2022, when she developed distal paresis of the right upper limb, changes in coordination, and dysarthria. Laboratory Investigation: MOG+, AQP4-, CSF unchanged. **Discussion:** Recently, the international diagnostic criteria for MOGAD (Myelin oligodendrocyte glycoprotein (MOG) antibody-associated disease) were published, and the diagnosis of MOGAD is now made based on the presence of at least one of the core clinical demyelinating events (optic neuritis, myelitis, ADEM, cerebral monofocal or polyfocal deficits, brainstem or cerebellar deficits, and cerebral cortical encephalitis often with seizures), a positive MOG-IgG test, and the exclusion of alternative diagnoses including MS. Approximately 30% of MOGAD cases are in the pediatric age group, and MOGAD comprises approximately 35-40% of cases of acquired CNS demyelinating syndrome in the pediatric population. When a MOG antibody is low-positive in a patient with a core clinical demyelinating event, at least one supporting clinical or MRI feature should be met to make a diagnosis of MOGAD since alternative diagnoses including MS can be low-positive. Approximately 35-50% of MOGAD cases have a relapsing course, with the relapse risk being slightly higher (~60%) in the young adult-onset group. Optic neuritis is the most common onset phenotype (~40%). Age-related onset phenotype is a feature of MOGAD, where ADEM is more common in pediatric patients <10 years old, while myelitis and brainstem encephalitis are more common in adult patients. **Final comments:** We describe a case of a pediatric patient with encephalopathy and optic neuropathy associated with anti-MOG antibodies, with extensive brain lesions, without spinal cord injury, but with a good response to pharmacological treatment. Recurrent condition, with the presence of the antibody persisting, even during treatment with corticosteroid therapy.

Molecular analyses of cell cycle-related genes in Rasmussen encephalitis

João Ismael Budelon Gonçalves[1], Marciéli Gerhardt[2], Vinicius Rosa de Castro[2], William Alves Martins[2], Fernando Xavier[1], Jaderson Costa da Costa[1], Eliseu Paglioli Neto[2], André Palmini[2], Daniel Marinowic[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Instituto do Cérebro, Porto Alegre RS, Brazil.

[2]Pontifícia Universidade Católica do Rio Grande do Sul, Hospital São Lucas, Porto Alegre RS, Brazil.

Correspondence: Marciéli Gerhardt; Email: marcieligerhardt@yahoo.com.br.

Case presentation: A 13-year-old boy presented a bilateral tonic-clonic seizure a few weeks after a self-limited viral illness. Neurological symptoms began 2 years earlier, with spasms in the left limbs, eventually associated with generalized tonic-clonic seizures. His medical history and development had been otherwise uneventful. After failing several antiseizure drugs, he was referred to our tertiary epilepsy center. At arrival, neurological examination showed spastic left hemiparesis and moderate to severe dysarthria, with continuous left hemiclonic motor seizures (epilepsia partialis continua [EPC]). MRI showed progressive right hemisphere and caudate atrophy, as well as hyperintensities in the right temporal and frontal lobes, extending throughout the right insula. EEG showed progressive slowing in the right hemisphere with periodic sharp waves over the right frontotemporal and parietal regions and frequent electrographic seizures. His symptoms led us to the diagnosis of probable Rasmussen's encephalitis (RE). Therefore, he underwent a right functional hemispherectomy. On the first postoperative day, he was awake and responsive and had no further seizures, although developed a transitory right third nerve palsy. He remained seizure-free six months after surgery (Engel IA) and has shown progressive motor improvement of the left leg and arm. Cortical tissue sample was obtained through functional hemispherectomy, and histopathology confirmed RE. Excised tissue was subjected to molecular analysis to evaluate the expression of cell cycle-related genes and protein levels of inflammatory cytokines, as well as neurotrophic factors. **Discussion:** RE stands as a rare neurological disorder marked by progressive cerebral hemiatrophy and epilepsy resistant to medical treatment. In this case report, we present a patient who underwent hemispherectomy and has remained seizure-free for over six months, experiencing gradual motor improvement. Despite extensive study, the primary cause of RE remains elusive, while its histopathological features comprehend cortical inflammation, neuronal degeneration, and gliosis. In our analyses, we found a general decreased expression of cell cycle-related genes in the brain tissue from our patient. The BRCA1, BIRC5, CASP3, E2F4 and CCDN genes were more than 5-fold downregulated. Alongside, levels of BDNF and TNF-α proteins were elevated. These findings suggest a potential involvement of cell cycle regulators in the progression of RE. **Final comments:** Molecular analyses may play an important role for understanding RE, as cell cycle-related genes might be involved in its physiopathology.

Molecular and clinical aspects of a Brazilian cohort of patients with variegate porphyria

Michelle Abdo Paiva[1], Beatriz Carneiro Gondim Silva[1], Rodrigo de Holanda Mendonça[1], Cristiane de Araujo Martins Moreno[1], Andre Macedo Serafim Silva[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Michelle Abdo Paiva; Email: michelle.abdop@gmail.com.

Background: Acute hepatic porphyrias (AHP) are a group of metabolic disorders of the heme biosynthesis Clinical aspects are very similar among acute intermittent porphyria (AIP), variegate porphyria (VP) and hereditary coproporphyria (HCP), regarding acute attacks and hereditary autosomal dominant pattern However, VP and HCP present with cutaneous symptoms. In most countries, AIP is believed to be the most common type of AHP followed by VP. Data from Brazil are still scarce due to lack of available specific biochemical exams and genetic studies. **Objective:** To describe epidemiological, clinical, and genetic profiles of patients with VP in a single tertiary center in Brazil. **Methods:** We included patients from our center with AHP as defined by the consensus of 2023, meaning typical heme precursors accumulation and/or a pathogenic variant in genetic exam. We reviewed medical history, medical records and complementary exams of all patients. A severe attack was defined with one or more of the following - significant hyponatremia, peripheral neuropathy, urinary retention or incontinence, central nervous system involvement and arrhythmias. **Results:** A total of 26 genetically confirmed AHP patients were identified in our hospital. VP was diagnosed in 13 patients from six different families. Ten patients were female, and 3 patients were male, with a mean age of 40 (22-55). The age at first symptoms ranged from 17 to 46 years. Four patients had two severe attacks, five patients had one severe attack, one patient had recurrent symptoms, not being possible to define the exact number, and three patients were asymptomatic. During the attack, seven patients experienced acute flaccid paralysis. Of these, three patients had seizures. Six patients presented psychiatric symptoms (anxiety, depression and/or psychosis). Acute phase electroneuromyography available for six patients with findings of axonal sensorimotor polyneuropathy for four cases, one patient with intermediate polyneuropathy, meeting CIDP criteria and one patient with only autonomic alterations. Acute confirmatory biochemical exams were available for five patients. Remaining cases had biochemical non conclusive biochemical exams or results not available. Skin lesions and/or photosensitivity were reported in five patients. Four families shared the same missense variant in exon 6, c503G> A of the PPOX gene, one patient with a deletion in exon 5-6 and one patient with a missense variant in exon 5 c.454C>T. **Conclusion:** Data from our center may suggest that VP is more common in our population than previously reported, as more than half of our patients with AHP had a pathogenic variant in PPOX. However, many from the same family, which may indicate a difference in penetration between AHPs. Clinically, patients may present similarly to other forms of AHP. Skin injuries may not be present in all patients. The lack of biochemical studies in our country may influence diagnostic accuracy.

Molecular therapy with gapmer antisense oligonucleotides (ASOS) in the treatment of Angelman syndrome

Giovana Pereira[1], Mariana Marques Rodrigues de Almeida[1], Luísa Ribeiro Dias Godoy[2], Vitória Aparecida Caetano[1], Thairine Alves Nascimento[1], Maria Fernanda Pascholati Penteado[1], Fernando Soares de Morais[1], Júlia Ribeiro Dias Godoy[2], Livia Maria Rodrigues de Almeida[3], Eduardo Freire Oliveira Figueiredo[1]

[1]Universidade Nove de Julho, Bauru SP, Brazil.
[2]Universidade do Vale do Sapucaí, Pouso Alegre MG, Brazil.
[3]Universidade Metropolitana de Santos, Santos SP, Brazil.

Correspondence: Giovana Pereira; Email: giovanapereira61@outlook.com.

Background: Angelman syndrome (AS) is a neurogenetic disorder caused by mutations that lead to the deactivation of the maternal allele of the UBE3A gene, present on chromosome 15. In neurons of the central nervous system (CNS), the UBE3A gene is subject to genomic imprinting, in which the maternal allele is expressed while the paternal allele is silenced by a long non-coding RNA called UBE3A-AS. Therefore, all people depend on the allele inherited from the mother to express the final product of the UBE3A gene, the E3A ubiquitin-protein ligase, responsible for directing certain proteins for degradation in brain tissue. The combination of paternal silencing of UBE3A and loss of maternal UBE3A expression results in the complete loss of expression of the neuronal protein UBE3A, compromising neuronal function and plasticity, justifying the severe neurological symptoms present in people with AS, including developmental delay, motor and cognitive deficits and seizures. Hyperactivity and hyperexcitability happen in 100% of cases, and they react to the slightest physical and mental stimuli with uncontrolled explosions of laughter, vocalizations (screams of excitement) and shaking hands (waving hands). **Objective:** Report the genetic pathogenesis and analyze the current perspectives for the management of AS based on molecular therapy with Gapmer antisense oligonucleotides (ASOs). **Methods:** Systematic literature review based on the PRISMA methodology. It was searched for articles indexed on the PubMed platform, in English language, in the last 10 years. 153 results were gathered, which were refined by the Ryyan platform and detailed by three independent reviewers. At the end of two analyses, 15 documents were fully reviewed. **Results:** Currently, there is no specific approved treatment for Angelman Syndrome. However, evidence suggests that molecular therapy with Gapmer antisense oligonucleotides (Gapmer ASOs) may be an effective therapeutic strategy. These modified oligonucleotides can modulate gene expression, increasing levels of functional proteins or improving the structure of altered proteins. Studies have shown that Gapmer ASOs can efficiently suppress the expression of the UBE3A-AS transcript and reactivate the expression of the paternal UBE3A allele in cultured human neurons, improving neurological deficits in mouse models of AS. These studies also demonstrated the feasibility and potential clinical benefit of a disease-modifying strategy for individuals with AS. **Conclusion:** Reactivating expression of the paternal UBE3A allele could be a powerful modifier treatment for AS, although further studies are needed to confirm efficacy in the human brain.

Monoclonal gammopathy: an uncommom, but not rare cause of peripheral neuropathy

Márcio Alves da Cruz Júnior[1], Carla Cristina Teixeira[1], Felipe Henriques Monteiro[1], Iago Collins Tavella Paulino[1], Liz Rocha Paes Hellbrügge[1], Lorenzo Batista Oliveira[1], Pietro Soares Motta[1], Suzana Rosa Silva[1], Daniel Sabino de Oliveira[1], Marcelo Maroco Cruzeiro[1]

[1]Universidade Federal de Juiz de Fora, Juiz de Fora MG, Brazil.

Correspondence: Márcio Alves da Cruz Júnior; Email: marcio.jr14@yahoo.com.br.

Case presentation: Case 1: white woman, 75 years old, hypertensive, depressive disorder and hypothyroidism with bilateral paresthesia in the lower limbs (LL) up to the level of the knees and progressive worsening within 8 months, paraparesis with distal predominance and burning pain in the feet. There were weight loss (8kg in 3 months), pain in the right hypochondrium, pleural effusion on the left side and was hospitalized. Tetraparesis with a predominance in the lower limbs, hyporeflexia, thermal and painful hypoesthesia up to the knees, reduced vibratory sensitivity up to the pelvic girdle, and ataxic-talonant gait were observed. Electromyography (EMG) revealed demyelinating sensory-motor neuropathy. Electrophoresis showed monoclonal peak, and bone marrow biopsy had hypercellularity, interstitial plasmacytosis, presence of CD138 and preferential expression of IgA/lambda light chain, referring to multiple myeloma. The diagnosis of POEMS Syndrome (polyneuropathy, organomegaly, endocrinopathy, monoclonal plasma cell disorder, and skin changes) has been established. Treatment with melphalan and dexamethasone was instituted (bone marrow transplant refused), evolving with partial motor clinical improvement. Case 2: A 67 year-old wthite Woman, with

hypertensive, diabetic, chronic venous insufficiency and fibromyalgia developed global weakness of all four limbs, numbness in boots and gloves, imbalance and frequent falls. The gait was ataxic, there was global areflexia, painful hypoesthesia and distal abscence of vibratory sensitivity of all four limbs, and EMG showed sensory-motor polyneuropathy of a demyelinating nature. Cerebrospinal fluid (CSF) had protein ncreased, and protein electrophoresis identified IgM/Lambda monoclonal peak. Multiple myeloma and lymphoproliferative diseases have been discarded. The measurement of antibodies against myelin-associated glycoprotein (anti-MAG) identified reactive IgM and non-reactive IgG. Chronic Demyelinating Inflammatory Polyneuropathy (CIDP) with distal variant (anti-MAG DADS) was diagnosed. Methylprednisolone pulse therapy monthly with partial improvement of the condition. **Discussion:** Monoclonal gammopathies (GM) are a heterogeneous group of diseases of hematopoietic system, which result from the production of immunoglobulins (Ig) by differentiated lymphocytes or monoclonal plasma cells and affect the peripheral nervous system by mechanisms not yet fully understood, such as deposition of Ig or amyloid substance, and its prevalence increases with age, reaching 10% around 80 years of age, especially in men. Both cases are due to the deposition of antibodies. Treatment is with corticosteroid therapy, intravenous human immunoglobulin, or immunosuppressants. **Final comments:** Monoclonal gammopathies, although uncommom, are not rare and should be part of the investigation in people from the sixth decade with neuropathy.

https://doi.org/10.5327/CBN241098

Mononeuritis multiplex following crotalid envenomation: a case report

Francisco Luciano Honório Barreto Cavalcante[1], Antônio Edvan Camelo Filho[1], Pedro Lucas Grangeiro de Sá Barreto Lima[1], Pedro Vitor Ferreira Rodrigues[1], Oliver Reiks Miyajima[2], Nahiana Bezerra de Menezes Cruz[3], Pedro Braga Neto[4], Paulo Ribeiro Nóbrega[4]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.
[2]Universidade Estadual do Ceará, Fortaleza CE, Brazil.
[3]Centro Universitário Christus, Fortaleza CE, Brazil.
[4]Universidade Federal do Ceará, Departamento de Medicina Clínica, Fortaleza CE, Brazil.

Correspondence: Francisco Luciano Honório Barreto Cavalcante; Email: francski2304@gmail.com.

Case presentation: A 34-year-old man was bitten on his left hand by a Crotalus durissus snake (rattlesnake) and suddenly developed pain and edema. The patient evolved in a few hours to a confusional state with lethargy, nausea, blurred vision, and dark urine. He was admitted to a reference center with laboratory tests revealing elevated liver enzymes and creatinine with myoglobinuria. He was treated with 20 anticrotalic serum (ACS) vials, each containing 10mL in a 1,5 mg/mL concentration. The patient had an allergic reaction to the serum, manifesting as periorbital and tongue edema. He was discharged after stabilization with normalization of liver and renal function. However, after three weeks, he presented with paresthesia and "needle-like" pain in his left hand and arm, which later progressed to his right hand. A week later, those symptoms progressed to his legs, which the patient described as a sensation of fatigue. An electroneuromyography (ENMG) was performed on the patient, showing an axonal, subacute, sensorimotor mononeuritis multiplex (MNM) in his four limbs, with ongoing denervation signs. An extensive investigation of potential causes of MNM was conducted, and the results were negative. He was treated with prednisone (1mg/kg) and pregabalin. Six months later, a new ENMG was performed with an expressive improvement of sensorimotor conduction without denervating activity in that exam. **Discussion:** Neurotoxicity due to crotalid venom usually occurs by a neuromuscular blockade, causing a myasthenic syndrome that presents with ptosis, mydriasis, ophthalmoplegia, and acute flaccid paralysis. Peripheral neuropathy (PN) is an atypical feature of snake envenomation. The literature points out that snake envenomation could cause local sensitive axonal mononeuropathy adjacent to the bite site, either due to the bite itself, compartment syndrome, or post-traumatic neuroma. Acute axonal sensorimotor polyneuropathy, both as an early or as a delayed presentation of envenomation, has been previously reported, with partial or complete recovery in months. As far as we know, this is the first case of MNM associated with crotalid snake envenomation. Another hypothesis is that a hypersensitivity reaction to the ACS could cause the MNM. Usual side effects of ACS include IgE-mediated reactions and serum sickness, which could cause PN. However, normal complement values and the lack of fever and skin changes weaken this hypothesis in the present case. **Final comments:** Snake envenomation is a common health issue in Brazil. Elusive manifestations of ophidic accidents or even unknown side effects of serum therapy, such as MNM, are still a challenge for physicians. Therefore, further studies are needed to better understand the relationship between those factors and improve snakebite victims' quality of life.

Morbidity and mortality from traumatic brain injury in infants under 1 year old in the state of São Paulo between 2018 and 2023

Yasmim Melo Costa de Azevedo[1], Victhor Luiz Senna de Moraes[2], Paula Ester de Oliveira Almeida[3], Victor Hugo da Silva Dias[4], Danielle de Souza Mometto[5], Sergio Gonçalves de Oliveira[6]

[1]Universidade Nove de Julho, São Paulo SP, Brazil.
[2]Universidade Federal Dos Vales do Jequitinhonha e Mucuri, Diamantina MG, Brazil.
[3]Faculdade de Minas, Belo Horizonte MG, Brazil.
[4]Universidade Cidade de São Paulo, São Paulo SP, Brazil.
[5]Universidade Potiguar, Natal RN, Brazil.
[6]Hospital Socor, Departamento de Neurocirurgia, Belo Horizonte MG, Brasil.

Correspondence: Yasmim Melo Costa de Azevedo; Email: yaxmelo@outlook.com.

Background: Traumatic brain injury (TBI) is one of the main causes of death and disability in childhood. It occurs due to an external trauma that results in anatomical changes and functional impairment. This incident is more serious in children, especially younger ones, than in adults, since the cervical ligaments and muscles are weaker, the skull is thin and flexible and the sutures are not yet fused. Common scenarios of occurrence in newborns are associated with the birth process, while in children they are associated with falls, aggression, or car accidents. However, despite its relevance, there is a gap in studies that investigate this topic and epidemiological data in Brazil. **Objective:** To analyze the epidemiological information on morbidity and mortality from traumatic brain injuries in infants under 1 year old in the state of São Paulo. **Methods:** Consists of a transversal and descriptive study with a quantitative approach. Based on information from the Hospital Admissions System (SIH/SUS) linked to DATASUS. The analysis involves raw data on hospitalizations, the number of cases that resulted in death, and the corresponding mortality rate due to Traumatic Brain Injury in infants under 1 year old in São Paulo from January 2018 to December 2023. This data was entered into Excel to establish the comparative evolution using percentages, aiming to organize temporal trends. **Results:** It was found that in the period analyzed, there were a total of 4273 hospitalizations. Regarding this result, we have that: 702 cases occurred in 2018, 739 in 2019, 749 in 2020, 718 in 2021, 639 in 2022, and 726 in 2023. Between 2021-2022 is the period with the greatest reduction, around 11%. During the entire period, simple variations were observed with the maintenance of trends proven by the 3% increase between 2018-2023. Regarding data on cases that evolved into deaths, there was a total of 42 in which the municipality that presented the highest number of deaths was São Paulo, with 9 cases, which represented around 21% of the total. Regarding the mortality rate, the municipality of São Paulo had the lowest (0.70) and Catanduva the highest (50.0). **Conclusion:** Thus, the effectiveness of therapeutic management in the good prognosis of patients is significant when comparing the number of total cases with those with the worst health outcome. Therefore, it is clear that the highest number of registered cases occurred in 2020, with 794 (17.5%). The drop in registration occurred in 2022, with 639 (14.9%). Furthermore, the polarity of results stands out when related to the variables that analyze the number of deaths and the mortality rate, with the capital of São Paulo being the highlighted representative. In this sense, a more compact data analysis, not yet widely explored, aims to promote impact through information and generate discussions to optimize the scenario of the injury presented in the state.

https://doi.org/10.5327/CBN241100

Mortality due to intracranial trauma in the elderly in Brazil: an ecological study (2008-2024)

Anna Gabriella Venâncio Neves de Moraes Tosta[1], David Cohen[2], Larissa Farah de Oliveira[3], Hadassa Lucena Sales Santos[4], Paulo Fernando Katsuo Ogatha Ito[5]

[1]São Leopoldo Mandic, Campinas SP, Brazil.
[2]Universidade Luterana do Brasil, Canoas RS, Brazil.
[3]Universidade Municipal de São Caetano do Sul, São Caetano do Sul SP, Brazil.
[4]Centro Universitário do Maranhão, Imperatriz MA, Brazil.
[5]Universidade para o Desenvolvimento do Estado e da Região do Pantanal, Campo Grande MS, Brazil.

Correspondence: Anna Gabriella Venâncio Neves de Moraes Tosta; Email: annagabriellatosta@gmail.com.

Background: Intracranial trauma (ICT) is one of the main emergencies and causes of morbidity and mortality in the elderly. Factors that favor a worse prognosis in the elderly include bone fragility, use of anticoagulants and antiplatelets, comorbidities, and previous level of consciousness. **Objective:** To analyze the morbidity and mortality due to intracranial trauma in the elderly in the Southeast Region between January 2008 and March 2024. **Methods:** This is an ecological, cross-sectional, descriptive study with a quantitative approach, conducted in May 2024, using data collected from the Hospital Information System of SUS (SIH/SUS - Sistema de Informações Hospitalares do Sistema Único de Saúde), available from the Department of Informatics of the Unified Health System (DATASUS - Departamento de Informática do Sistema Único de Saúde). The variables used were hospitalizations, total cost, deaths, and mortality rate. The collected data were organized in Microsoft Excel spreadsheets and analyzed using descriptive statistics. **Results:** The analysis revealed mortality rates, deaths, hospitalizations, and total cost, respectively, for each state in the Southeast Region. In Minas Gerais, the mortality rate was 13.10% (6,765 deaths and 51,626 hospitalizations) with a total cost of R$116,313,880.46; in Espírito Santo, the mortality rate was 13.51% (1,135 deaths and 8,399 hospitalizations) with a total cost of R$18,792,052.87; in Rio de Janeiro, the mortality rate was 21.79% (5,723 deaths and 26,269 hospitalizations) with a total cost of R$48,345,157.04; in São Paulo, the mortality rate was 17.82% (18,116 deaths and 101,633 hospitalizations) with a total cost of R$206,647,673.22. Thus, it was possible to analyze that, although Rio de

Janeiro and Minas Gerais have a similar total population, Rio de Janeiro has the highest mortality rate. This suggests differences in socioeconomic conditions, access to healthcare, or quality of medical services. Factors such as income distribution, education, employment, distribution of hospitals and healthcare professionals, as well as the efficiency and effectiveness of treatments, can influence these variations in mortality rates. **Conclusion:** The data examined from January 2008 to March 2024 highlight the discrepancy in morbidity and mortality between Minas Gerais and Rio de Janeiro. Therefore, greater attention and search for prevention strategies, such as investment in elderly care policies, as well as medications capable of preventing conditions that may lead to possible brain trauma and reduce morbidity and mortality, are necessary.

https://doi.org/10.5327/CBN241101

Mortality due to malignant neoplasm of the CNS in children under 20 years old in Brazil

Gabriel Cordova[1], Emanuel Henrique dos Santos[1], Izabelly Constantinov Lemos[1], Kauan Correia Derbli[1], Anne Beatriz Ricardo Amaral[1], Sofia Beatriz Andrade Manfio[1], Julia Farto Viana Oliveira[2], Gabriel André Silvério[1]

[1]Centro Universitário Campo Real, Guarapuava PR, Brazil.
[2]Universidade Estadual do Centro-Oeste, Guarapuava PR, Brazil.

Correspondence: Gabriel Cordova; Email: gabrielcordovah15@gmail.com.

Background: Malignant Neoplasm of the Central Nervous System (CNS) comprises a spectrum of malignant brain tumors that detrimentally impact neurological functions. It is typified by the invasive and unbridled proliferation of aberrant cells within the encephalic tissue, exhibiting aggressive infiltration into the adjacent tissues, with the capacity to originate in both the encephalon and the spinal cord. **Objective:** To compare the mortality rate of children under 20 years old due to CNS cancers across the different Brazilian regions. Additionally, the study aims to analyze which gender is most affected by this condition, as well as to determine the most common anatomical location of this neoplasm within the CNS. **Methods:** An epidemiological study using the DATASUS database, covering 2017-2021. Constants included deaths by region and age group. Brazil was divided into North, Northeast, Southeast, South, and Central-West. Variables included sex, age (0 to 19 years), and neoplasm location. ICD codes used were C70, C71, and C72. Additionally, Tabnet data of the resident population in each region for the same period was used to determine the exposed population (n= 100,000). **Results:** From 2017 to 2021, the number of total deaths was respectively: 642, 593, 609, 552 and 590. Of these, 5.09% occurred in children under 1 year. The Southeast had the highest rate of deaths, responsible for 37.61%, followed by the Northeast (29.71%), South (14%), North (10.25%) and Central-West (8.44%). Among the ones under 20 years old and over 1 year, the average mortality rates during the period of the study, in descending order was, 1.06 in the Central-West, 1.05 in the South, 0.99 in the Northeast, 0.96 in the Southeast and 0.91 in the North. Thus, the Central-West and the South regions had the highest mortality rates. In those, under 1 year, the Northeast (1.23) and North (1.16) led the ranking of the average mortality rate, followed by the South (1.15), Southeast (1), and Central-West (0.75). Of all deaths due to malignant neoplasm of the CNS, 53.48% occurred in males (n= 1597) and 46.52% in females (n= 1389). Regarding the anatomical location, 81.42% of neoplasms were located in the encephalon, followed by 18.04% located in the spinal cord, cranial nerves, and other parts of the CNS, and 0.54% in the meninges. **Conclusion:** The Central-West and South regions had the highest mortality rates, in those under 20 years and over 1 year. On the other hand, the North and Northeast regions had the highest mortality rates among those under 1 year. The sex with the highest number of deaths was male. In addition, more than 80% of neoplasms were located in the encephalon. Thus, further research is required to understand the mortality rates of children in each region, ensuring an accurate grasp of epidemiology and promoting the physical, mental, and social well-being of the Brazilian population.

Mortality from Alzheimer's disease in Bahia, 2017-2022

Mariela Sousa dos Santos[1]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.

Correspondence: Mariela Sousa dos Santos; Email: mariellasanttos5@gmail.com.

Background: Alzheimer's disease (AD) is the most usual type of dementia among the elderly and it's cognitive and neuropsychiatric manifestations result in progressive disability and incapacitation. It is characterized, histopathologically, by massive synaptic loss and neuronal death observed in brain areas responsible for cognitive functions, including the cerebral cortex, hippocampus, entorhinal cortex and ventral striatum. It is the main cause of functional dependence and mortality among the elderly population. Socioeconomic aspects and genetic modifications may be linked to AD. **Objective:** Measuring the prevalence of Alzheimer's disease mortality rate and potential associated socioeconomic determinants among the population of Bahia, 2017-2022. **Methods:** A descriptive, retrospective, time series study was carried out to evaluate Alzheimer's mortality rate evolution in Bahia, from 2017 to 2022. Death due to Alzheimer's disease happens when the disease is listed as the cause of death in the Death Declaration (DO). The G30 code of the International Classification of Diseases, 10th revision (ICD-10) was considered. To calculate mortality rates, we used the number of deaths available in the International Mortality System (SIM), population data from 2000 to 2021 censuses and the 2022-panorama census, from the Brazilian Institute of Geography and Statistics (IBGE). Standardized mortality rates per 100,000 inhabitants with Alzheimer's disease as the underlying cause used the census population from 2017 to 2022. Data were analyzed using SPSS software, version 17.0 **Results:** In the period between 2017 and 2022, 600,760 deaths were registered in the SIM in Bahia, of which 1% had Alzheimer's disease as the cause mentioned in the DO. Considering all central nervous'"s system deaths between 2017 and 2022, the general prevalence of mortality from Alzheimer's was 45.5% among all deaths, being more frequent in women, mixed race/color, and age group ≥80 years old. **Conclusion:** High prevalence of mortality from Alzheimer's disease. Socioeconomic factors associated with the outcome were age group, race/color and sex.

Mortality from cerebral palsy in Brazil between 2013 and 2022

Ana Carolina Ribeiro de Araujo e Araujo[1], Aeriberto Carlos Lindoso de Souza[1], Consuelo Penha Castro Marques[1], José Carlos Gomes Patriota Neto[1]

[1]Universidade Federal do Maranhão, Pinheiro MA, Brazil.

Correspondence: Ana Carolina Ribeiro de Araujo e Araujo; Email: anacarolinaraa@hotmail.com.

Background: Cerebral palsy is the main cause of disability in children, caused by permanent and non-progressive damage to the central nervous system during the fetal period, at birth or in early childhood, generating serious complications in the development of skills, tone, reflexes and the posture. In Brazil, for every 1,000 children born, 7 are carriers of this paralysis, in addition, it is estimated that there are around 30,000 to 40,000 new cases per year. Diagnosis involves a complete neurological examination, finding delay in motor development, persistence of primitive reflexes and presence of abnormal reflexes. **Objective:** To investigate mortality from cerebral palsy in Brazil between the years 2013 and 2022. **Methods:** Quantitative, descriptive, time series and ecological study of deaths from cerebral palsy in Brazil, during the period from 2013 to 2022, with data from the System of Information on Mortality - SIM, available from the Information Technology Department of the Unified Health System (TABNET/DATASUS). The variables used were: region, age group, sex, education, marital status and place of occurrence. **Results:** n=14,371 deaths due to cerebral palsy were reported in Brazil during the study period, with the region with the highest incidence being the Southeast, with n=5,803 deaths, followed by the Northeast n=3,846 and the South n=2,656, affecting mainly age ranges from children under 1 year of age to 29 years of age, representing 70.6% of cases. Furthermore, cerebral palsy was mostly found in males (56.7%), especially in individuals with little or no education (69.3%), in singles (78.9%), being the main place of occurrence of deaths in hospital n=9,010, followed by home n=4,144 and other health establishments n=951. **Conclusion:** Given the above, it can be concluded that cerebral palsy has a higher prevalence of deaths in individuals younger than 29 years of age, showing a lower life expectancy of these patients. That said, supportive treatments and delaying the progression of the pathology become necessary for the well-being and life expectancy of these individuals. Given the evolution of treatments and technologies focused on the neurological area, it is necessary to further evolve the neurological treatment of specific paralysis.

https://doi.org/10.5327/CBN241104

Mortality from CNS tumors in the state of Minas Gerais over the past 25 years

José Victor Ribeiro Silva Gomes[1], Kananda Oliveira Garcia Ruiz[1], Cínthia Emanuelle da Costa Sousa[1], Rodrigo Chávez-Penha[1]

[1]Universidade Federal de São João del-Rei, São João del Rei MG, Brazil.

Correspondence: José Victor Ribeiro Silva Gomes; Email: josevrsgomes@gmail.com.

Background: Central Nervous System (CNS) tumors are neoplasms originating from tissues in the brain and in the spinal cord. They are estimated to be the 11th most common type of cancer in Brazil between 2023 and 2025. Its rising number of cases and deaths worldwide claims for better understanding of its trends. **Objective:** Describe mortality due to central nervous system (CNS) neoplasms in adults in the Brazilian state of Minas Gerais (MG). **Methods:** this is an ecological time-series analysis with data from DATASUS regarding deaths from all kinds of CNS neoplasms in adults of 20 or more years old residing in MG between the years 1998 and 2022, by age group and reported cause of death as in the ICD10. Joinpoint analysis was used to verify trends in age adjusted mortality rate per 100.000 people (MR) by annual percentage change (APC). **Results:** 19,537 deaths were recorded in MG in the period, most of them in the 60-69 age group (24.5%) and in men (52.2%). 77.7% of deaths (15,185) occurred due to malignant neoplasms of the brain (ICD C-71). Overall MR due to CNS tumors showed 2 identifiable trends: an increase (APC 2.44) from 1998 (MR 5.86) to 2006 (MR 6.89) and a decrease (APC -0.73) from 2006 to 2022 (MR 5.54). MR trends in men followed that pattern, but with an increase (APC 1.32) from

1998 (MR 6.28) to 2012 (MR 7.29), followed by decrease (APC -1.32) until 2022 (MR 6.23). Women MR trend was of reduction through the whole period (APC -0.13; 1998 MR 5.64 to 2022 MR 4.90). MR by age group showed very different patterns, with an increase for the 50-59 (APC 0.31) and 80 or more years old (APC 0.83) groups, and decrease in the other groups (APCs: 20-29: -0.15; 40-49: -0.81; 60-69: -0.02; 70-79: -0.28). As for identified deaths related to CNS tumors, malignant tumors were responsible for the highest MR and all showed an increase in different patterns followed by reductions. Trends of MR for malignant neoplasm of meninges (C70) increased (APC 3.72) from 1998 (MR 0.25) until 2010 and then decreased (APC -5.50) up to 2022. As for trends of MR for malignant neoplasms of the brain (C71) raised (APC 1.83) from 1998 (MR 10.3) till 2006 (MR 11.25) to then reduce (APC -1.70) until 2022 (MR 7.54). Finally, trends of MR for malignant neoplasms of spinal cord, cranial nerves and other parts of central nervous system (C72) increased (APC 8.14) from 1998 (MR 0.35) until 2017 (MR 2.25) and then decreased (APC 8.73) until 2022 (MR 1.50). **Conclusion:** Deaths from CNS neoplasms, although less common compared to other tumors, have become more frequent in Minas Gerais. The identified trends may raise concerns on the attention to CNS tumors in men, elderly people and malignant neoplasms of the brain through the studied period. Further investigation is needed to assess if the MR and trends identified relate to changes in the population age distribution, quality and accessibility to medical care.

[4]Fundação Educacional de Fernandópolis, Fernandópolis SP, Brazil.

Correspondence: Larissa Bianca Borsone; Email: larissa.borsone@hotmail.com.

Background: Viral meningitis results from inflammatory processes affecting the membranes that cover and protect the central nervous system, including the brain and spinal cord. It is a significant public health problem due to its high morbidity and mortality rates, complicated neurological sequelae, and transmission potential, which can lead to epidemic outbreaks. **Objective:** To evaluate the mortality profile from viral meningitis in Brazil between 2011 and 2020. **Methods:** Data collection was performed using publicly available information from the Mortality Information System (SIM) of the Ministry of Health in the Tabnet/DATASUS database between May 1 and July 22, 2023. This retrospective longitudinal study employed a quantitative descriptive approach. Data were grouped by age and educational level for the period from 2011 to 2020. Statistical inference was conducted using BioEstat 5.3 software, utilizing the Friedman test for group comparisons, and data presentation included descriptive statistics, measures of central tendency, and dispersion. **Results:** Between 2011 and 2020, there were 608 deaths from viral meningitis in Brazil. The highest number of deaths occurred in the Southeast region (261), corresponding to 42.93% of the total, and 132 (21.71%) cases in the South (p<0.0001). The Central-West (n=50, 8.22%) and North (n=52, 8.55%) regions had the lowest number of deaths. In terms of annual distribution, 75 (12.34%) deaths occurred in 2017 compared to 8.06% (49) in 2011, with no significant increase in deaths between 2011 and 2020 (p=0.1921). Regarding sex, 57.07% (n=347) of the deaths occurred among males and 42.93% (n=261) among females (p=0.0269). In terms of age, 293 cases (48.19%) occurred among individuals aged 20 to 59, and 29.64% (162) were aged 60 and over. The least affected age groups were those up to 9 years (15.63%, n=95) and 10 to 19 years (9.54%, n=58) (p<0.0001). Regarding education, 134 cases had 8 to 11 years of schooling (22.04%), and 129 (21.22%) had 4 to 7 years (p<0.0001). In terms of race/ethnicity, the majority were white (295, 48.52%), followed by mixed race (237, 38.98%), black (51, 8.39%), yellow (4, 0.66%), indigenous (4, 0.66%), and 17 (2.80%) were not reported (p<0.0001). **Conclusion:** In conclusion, patients who died from viral meningitis in Brazil tended to be from the Southeast and South regions, aged between 20 and 59 years, predominantly male, and of white or mixed race, with an average of 4 to 11 years of schooling. Keywords: Mortality; Viral Meningitis; Brazil.

Mortality of viral encephalitis in children and adolescents in the Brazilian Midwest: an epidemiological study over the past 15 years

Gustavo Hayasaki Vieira[1], Giovana de Oliveira Araújo[1], Gustavo Cartaxo de Sousa Melo[1], Isabela Maciel Mesquita[1], Milena Almeida Barbosa[1], Paulo André Silva Miranda[1], Paulo Sérgio Machado Diniz[1], Rafaella Rodrigues de Freitas Vieira[1], Samira Dionísio Maia[1], Valentina Melo Rosa Centofanti[1]

[1]Pontifícia Universidade Católica de Goiás, Goiânia GO, Brazil.

Correspondence: Gustavo Hayasaki Vieira; Email: gushayasaki@gmail.com.

Background: Viral encephalitis is a rare condition affecting approximately 1.4 individuals per 100.000 annually worldwide. It is characterized by inflammation of the brain parenchyma due to common viral infections in Brazil, such as dengue, Zika, and chikungunya. Given the high mortality associated with viral encephalitis and the lack of studies focusing on the Brazilian Midwest and, more specifically, the pediatric population, conducting an epidemiological analysis of mortality cases in this region is crucial. **Objective:** To analyze the epidemiological profile of mortality cases due to viral encephalitis in the pediatric population of the Brazilian Midwest from 2008 to 2023. **Methods:** This is a descriptive, retrospective, and quantitative epidemiological study based on data from the Hospital Information System (SIH/SUS) provided by the Department of Information Technology of the Unified Health System (DATASUS), regarding the mortality from viral encephalitis in pediatric patients from 2008 to 2023 in Goiás, Mato Grosso, Mato Grosso do Sul, and Distrito Federal. Filters applied included: ICD-10 morbidity list (viral encephalitis), midwest region, race/ethnicity, gender, age group, available period (January 2008 to December 2023), and year of processing. Data were tabulated in Excel and subjected to descriptive statistical analysis using R 4.40 with RStudio 2024.04.1 + 748. Since this study utilizes publicly available anonymous data, it is exempt from the Ethics Committee's approval. **Results:** During the study period, the average mortality rate was 2.85 %, with 2012 having the highest mortality rate (6.9%) followed by 2009 (6.45%). On the other hand, records from 2023 show the lowest mortality rate, 1.02%. Among the analyzed regions, Mato Grosso exhibited the highest mortality rate (4.12%), whereas Distrito Federal had the lowest (1.93%). Notably, individuals of indigenous ethnicity were most affected, with a mortality rate of 12.5%. Additionally, males showed a higher mortality rate compared to females, with rates of 3.49% and 1.95%, respectively. The most affected age group was 10-14 years, with a mortality rate of 4.62%. **Conclusion:** This study identified the indigenous population as vulnerable to viral encephalitis, likely due to geographical isolation and insufficient healthcare services available. Therefore, there is a clear need to invest in public health policies targeted at this social minority. It is also worth mentioning that Mato Grosso had the highest mortality rate, while the Federal District had the lowest. Furthermore, the highest mortality rates were concentrated about 10 years ago, notably in 2009 and 2012, while there is a decreasing trend in mortality rates, as demonstrated by the 2023 rate, the lowest recorded in the study. Given the data analysis, further studies are needed to investigate the factors influencing the correlation between mortality and viral encephalitis in the Brazilian Midwest regions.

Mortality rate and average length of stay of hospitalizations for the treatment of polyneuropathies in Brazil by region in the last 6 years

André Luiz Borges Silva[1], Arthur Cauã Silva Santos[2], Igor José Balbino Santos[1], Isaias Felipe dos Santos[1], João Gabriel Dantas Cunha[2], Crisdan Cainã Costa Chagas[2], Helton Benevides Santana de Oliveira[1]

[1]Universidade Federal de Sergipe, São Cristóvão SE, Brazil.
[2]Universidade Tiradentes, Aracaju SE, Brazil.

Correspondence: Andre Luiz Borges Silva; Email: andre.borges297@gmail.com.

Background: Polyneuropathies refer to a group of conditions characterized by diffuse damage to peripheral nerves, typically associated with symmetric sensory loss and a length-dependent pattern. With a heterogeneous neurological presentation and potentially severe outcomes, they often require hospital admission for appropriate etiological investigation, treatment of underlying causes, and management of possible complications arising from the neurological condition. **Objective:** To compare the mortality rate and the average length of stay of hospitalizations for the treatment of polyneuropathies in Brazil by region over the past 6 years, in order to contribute to future strategies for addressing these diseases. **Methods:** This is a descriptive study with secondary data, retrospective and quantitative in nature. The data were obtained from the Department of Informatics of the Unified Health System (DATASUS). Mortality rates and average lengths of stay for hospitalizations due to polyneuropathies in Brazilian regions between 2018 and 2023 were analyzed. The data are public domain, hence there was no need for submission to the Ethics and Research Committee. **Results:** In the Northern region, the average annual mortality rate for hospitalizations for the treatment of polyneuropathies was 2.22. In the Northeast, this value was 2.22; in the Southeast, it was 2.26; in the South, 1.54; and in the Midwest, 2.80. Regarding the average length of stay per hospitalization, in days, the Northern region had an average of 8.93 days; in the Northeast, this average was 8.75; in the Southeast, 9.61 days; in the South, 6.90; and in the Midwest, 9.76 days. Considering that these values involve averages and percentage data, the total sample size (resident population) does not significantly influence the reliability of the data. **Conclusion:** The study showed significant regional variations in the mortality rate and the average length of stay for hospitalizations for the treatment of polyneuropathies in Brazil between 2018 and 2023. The Midwest region had the highest mortality rates and average lengths of stay, while the Southern region had the lowest numbers in both variables, indicating the need for interventions to reduce significant differences in the quality of care between different regions of the country. The limitations of the type of research conducted include the impersonal nature of the study, making it difficult to seek causality for the data found. Therefore, a recommendation for future studies is direct research to identify more specifically the needs of each region.

https://doi.org/10.5327/CBN241108

Mortality rate in patients with neuromyelitis optica at a university hospital

Mackeyle Siqueira de Souza[1], Sávio Cesar Rodrigues Pestana[1], Vinícius Andreata Brandão[1], Igor Flavio Gonçalves do Vale[1], Victória Pagani Samora Sousa[1], Paula Zago Melo Dias[1], Bruno Batitucci Castrillo[1], Carlos Alberto Magirius Peixoto[1]

[1]Universidade Federal do Espírito Santo, Vitória ES, Brazil.

Correspondence: Igor Flavio Gonçalves do Vale; Email: igor.f.vale@edu.ufes.br.

Background: Neuromyelitis optica spectrum disorder (NMOSD) is an autoimmune condition characterized by acute attacks of optic neuritis and transverse myelitis, often associated with autoantibodies against aquaporin 4 (AQP4-IgG). Commonly used preventive therapeutics, including Azathioprine, Mycophenolate, and Rituximab, have helped control the disease by reducing immune system activity. Although these treatments have demonstrated clinical significance in the stabilization of NMOSD, their effectiveness is not absolute. **Objective:** Evaluate the mortality rate in patients with positive anti-AQP4 NMOSD at the university hospital **Methods:** This retrospective study was conducted at a public neurology outpatient clinic in Espírito Santo, Brazil, over a two-year period. Electronic medical records of patients diagnosed with NMOSD and receiving treatment were reviewed to assess the mortality rate within the local neurology service. **Results:** Of the 37 patients studied (6 men and 31 women), there were 2 deaths representing 5.4% of the cohort. One male and one female died after complications from a severe spinal cord attack. Both were using azathioprine and had therapeutic failure, and were awaiting release of rituximab. **Conclusion:** At the beginning of the neuromyelitis optica descriptions in the 1920s, mortality in 5 years was 32%. With preventive treatments, there was a significant reduction in mortality, which in our sample was 5.4%. However, it still represents a high mortality rate, similar to that of Guillain-Barré, demonstrating the need for public policy to treat this condition.

Motor alterations in children with autism spectrum disorder level 3, according to the operationalized portage inventory: a cross-sectional study

Gabriela Batista Santos[1], Laércio da Silva Paiva[1], Débora Bachin Carvalho[2,3], Noelia Barbosa de Oliveira[3], Lívia Joela Almeida de Lima e Silva[3], Clara Criez de Lima Santos[3], Lucas Tomita Sodré[3], Marina Ortega Golin[1]

[1]Centro Universitário Faculdade de Medicina do ABC, Santo André SP, Brazil.
[2]Universidade Nove de Julho, São Paulo SP, Brazil.
[3]FisioPETI, São Paulo SP, Brazil.

Correspondence: Débora Bachin Carvalho; Email:

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder classified into three levels of severity. Level 3 is the one that requires the most support, with the greatest restrictions on independence. In order to identify motor alterations in these children, it is necessary to use assessment scales. The most widely used in this population is the Operationalized Portage Inventory (OPI), which assesses six areas of development (gross and fine motor skills, cognition, socialization, language and self-care). **Objective:** To analyse overall motor performance of children with ASD level 3, according to the OPI, and to check the correlation with performance in language, cognition, self-care and socialization. **Methods:** This is a retrospective observational cross-sectional study analyzing 40 medical records of children aged between three and six years old diagnosed with ASD level 3, seen at FisioPETI Rehabilitation Clinic in São Bernardo do Campo / SP. The project was approved by the Research Ethics Committee of the Faculdade de Medicina do ABC University Center, protocol no. 70212423.6.0000.0082. The following data was collected: age; gender, Childhood Autism Rating Scale (CARS) score, classification of the development (in years) and quantification of developmental delay (in months) in each dimension of the OPI. Pearson's correlation test was used to relate the delay in overall motor performance to the other dimensions. The sample power calculation to quantify the delay in global motor performance was 100%. **Results:** Among the 40 patients, 62.50% were male, 97.50% showed delay in global motor development and self-care and 100% in language, cognition and socialization. The median age was 4.0 years old, global motor development, 2.1 (years); self-care, 2.2; socialization, 1.4; cognition, 1.2; and language, 0.4. The extent of delay in motor development (average) was 21.67 months; in self-care, 23.12; in socialization, 33.1; in cognition, 34.6 and language, 43.62. Delayed motor development showed a significant correlation with all other areas of development assessed by the OPI ($p<0.001$). **Conclusion:** Delayed global motor development was identified by the OPI in almost all children with ASD level 3. However, it was less severe, especially when compared to cognitive and language delays. The extent of developmental delay in all dimensions was correlated.

Motor and respiratory function in young children with LAMA2 congenital muscular dystrophy

Mariana Cunha Artilheiro[1], Alulin Tácio Quadros Santos Monteiro Fonseca[1], Tatiana Ribeiro Fernades[1], Cristiane Araújo Martins Moreno[1], Umbertina Conti Reed[1], Edmar Zanoteli[1], Clara Gontijo Camelo[1]

[1]Universidade de São Paulo, Faculdade de Medicina, São Paulo SP, Brazil.

Correspondence: Alulin Tácio Quadros Santos Monteiro Fonseca; Email: alulin.fonseca@gmail.com.

Background: The manifestation of weakness in the skeletal and respiratory muscles in patients with LAMA2 Congenital Muscular Dystrophy (LAMA2-CMD) typically occurs after birth or during early childhood. Data related to the young children population are less frequently published compared to older patients. However, assessments at young ages are crucial for prevention, early detection and treatment of complications. **Objective:** To identify motor and respiratory changes over the period of 2 years in young children with LAMA2-CMD. **Methods:** Eight LAMA2 children (6 female, 2 male) were assessed annually for a period of 2 years to monitor the evolution of their range of movement (ROM), motor function (Motor Function Measure - MFM D1, D2, D3 and total score -, and Revised Upper Lim Module - RULM) and respiratory function (measured by spirometry over 4 years old). The mean age for the first assessment was 3 - 1.75 years old and 4.62 - 1.19 years old for the second assessment. The analysis was conducted using descriptive statistics. **Results:** ROM: for hip extension, 4 children showed a worsening of 5-250, while 4 maintained their ROM; for knee extension, 4 children showed a worsening of 10-200 and 4 also maintained their ROM. Motor function: for upper limb function, 3 children showed a decrease of 3-9 points in the RULM score, while 3 children increased their RULM score by 3-6 points; two children maintained their score; for MFM D1 (standing position and transfers), 4 children showed worsening of 1-5%, 2 have increased the score between 4-8% and other 2 maintained their score; for MFM D2 (axial and proximal function), 7 children showed a decrease between 3-33%, while only one maintained their score; for MFM D3 (distal function), 3 children showed a decrease of 6-17%, while 3 children increased between 5-10% and 2 children maintained their percentages; for MFM total score, 4 children showed a decrease of 1-7%, while 2 children increased between 1-3% and 2 children maintained their percentages. Respiratory function: assessments were obtained only in 2 children; one child showed maintenance of the forced vital capacity (FVC) and another one increased the FCV in 5%. **Conclusion:** In two years, LAMA2 children between 2 and 6 years old showed the most evident deterioration in hip and knee ROM, as well as in the MFM D2 score. Upper limb function assessed by RULM and MFM D3 showed variable changes, which could either remain stable or change significantly, above 3 points up or down. On the other hand, MFM D1, MFM total score and respiratory function showed few significant changes over a 2-year follow-up.

Correspondence: Mariana Hiromi Manoel Oku; Email: mari.hiromi.mo@gmail.com.

Background: Sjogren syndrome (SS) is an autoimmune disease with a predilection for the peripheral nervous system that can precede in years systemic involvement. Motor neuron disease (MND) has been described in association with SS in a few case reports but it represents a rare presentation. **Objective:** To describe a case series of patients with an overlap between MND and SS. We discuss diagnostic clues and challenges, our treatment experience, and neurological response at follow-up. **Methods:** Data was collected from medical records between February 2021 and May 2024. We describe five patients, including epidemiologic and clinical characteristics, rheumatologic investigation, electromyography, magnetic resonance imaging (MRI), and treatment. **Results:** We identified five caucasian female patients with signs of MND and a concomitant diagnosis of SS after systemic review. Median age was 40 years old. Three developed both upper and lower motor neuron symptoms (LMN), the other two presented LMN symptoms only. Asymmetrical weakness was the initial symptom in three patients while the others had symmetric weakness. Two also displayed prominent bulbar and respiratory involvement. Electromyography of all patients showed signs of active denervation and reinnervation in at least one segment. All patients presented with Sicca Syndrome in addition to a positive Anti-Ro/SSA antibody and four met the European League Against Rheumatism (EULAR) diagnostic criteria by either having a confirmatory salivary gland biopsy and/or a positive Schirmer test. Three cases had a positive antinuclear antibody. Plexus MRI was performed in two patients, with plexus enhancement in one case and plexus thickening with no enhancement in the other. Cerebrospinal fluid (CSF) of three patients exhibited albuminocytologic dissociation (average protein level of 65 mg/dL). All patients received corticotherapy and immunoglobulin, three received rituximab, and one received cyclophosphamide. Disease progression was observed in three patients

despite any treatment whereas the other two had a partial response. The best outcome was observed in one patient who received immunoglobulin with no initial response followed by corticosteroids and rituximab, which led to neurological stabilization. She displayed only LMN symptoms, had plexus enhancement in MRI, and had the highest CSF protein level (99 mg/dL). The other patient who showed weakness improvement also had LMN symptoms exclusively and received corticotherapy and immunoglobulin. **Conclusion:** Sjogren syndrome seldom presents with MND. In our case series, most patients displayed both signs of upper and lower motor neuron symptoms. Response to immunotherapy was minor if compared to other neurological manifestations of SS, inferring a possible worse outcome related to this presentation. Further investigation is paramount for a better understanding of the association between the two diseases.

Motor performance in children with autism spectrum disorder level 1, according to the portage inventory: a cross-sectional study

Vitória Hikari Ucima[1], Laércio da Silva Paiva[1], Débora Bachin Carvalho[2,3], Noelia Barbosa de Oliveira[3], Lívia Joelma Almeida de Lima e Silva[3], Clara Criez de Lima Santos[3], Lucas Tomita Sodré[3], Marina Ortega Golin[1]

[1]Centro Universitário Faculdade de Medicina do ABC, Santo André SP, Brazil.
[2]Universidade Nove de Julho, São Paulo SP, Brazil.
[3]FisioPETI, São Paulo SP, Brazil.

Correspondence: Débora Bachin Carvalho; Email: dbachinc@gmail.com.

Background: Autism Spectrum Disorder (ASD) includes individuals who have global neurodevelopmental disorder. The severity of the commitment in ASD is classified in three levels On level 1, the individual shows problems while interacting, but with considered ability to be reajusted to the social environment. The Operationalized Portage Inventory (OPI) assesses the functions performed by these children. Most studies report only cognitive and social alterations in this population. **Objective:** To analyse the global motor performance of children with ASD level 1, according to the OPI, and to check the correlation with language, cognition, self-care and socialization performances. **Methods:** This is a retrospective observational cross-sectional study, analyzing medical records from FisioPETI Rehabilitation Clinic, São Bernardo do Campo / SP. The project was approved by the Research Ethics Committee of the Faculdade de Medicina do ABC University Center, protocol no. 70199623.0.0000.0082. A total of 49 medical records was selected and the following data was collected: age, gender, Childhood Autism Rating Scale (CARS) score, developmental classification (in years) and quantification of developmental delay (in months) in each dimension of the OPI. Pearson's correlation test was used to relate the delay in overall motor performance to the other dimensions. The power of the sample to quantify delay in overall motor performance was calculated at 100%. **Results:** Among the 49 children, 77.55% were male, 97.96% had delay in overall motor development, 100% in language development, 95.92% in cognition, 100% in socialization and 95.92% in self-care. The average age was 4.04 years old; CARS score, 25.32; global motor development, 3.22 (years); self-care, 2.93; cognition, 2.64; socialization, 2.36 and language, 1.80. The average delay severity was: 11.53 months in global motor development, 14.91 in self-care, 18.48 in cognition, 21.83 in socialization and 28.67 in language. A significant correlation was found between the severity of the delay in global motor development and the other areas of development ($p<0.001$). **Conclusion:** The majority of children with ASD level 1 showed delay in motor development, but with less severity than in other areas of development. The areas with the highest proportion of impairment and extent were language and socialization. The severity of motor impairment was correlated with that of language, socialization, cognition and self-care.

Motor unit number index (MUNIX) as a biomarker for disease progression in late-onset 5q-spinal muscular atrophy treated with nusinersen

Rodrigo de Holanda Mendonca[1], Jose Pedro Soares Baima[1], Antonio Edvan Camelo Filho[1], Graziela Jorge Polido[1], Carlos Otto Heise[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, Departamento de Neurologia, São Paulo SP, Brazil.

Correspondence: Rodrigo de Holanda Mendonça; Email: rodrigo.holanda@hc.fm.usp.br.

Background: The Motor Unit Number Index (MUNIX) has emerged as a more sensitive biomarker for detecting motor unit loss in 5q-spinal muscular atrophy (SMA) compared to compound muscle action potential (CMAP). Recent studies have shown correlations between MUNIX values of various muscles and motor scales used to assess disease progression and treatment response. **Objective:** This study is an investigation of the feasibility of MUNIX as a biomarker for disease progression in SMA types 3 and 4 treated with nusinersen. **Methods:** A four-year study involved 20 patients diagnosed with SMA types 3 and 4, ten treated with nusinersen and ten non-treated. Patients underwent evaluations using the Hammersmith Functional Motor Scale Expanded (HFMSE), the 6-minute walk test (6MWT), and assessments of CMAP and MUNIX in the abductor policis brevis (APB), adductor digiti minimi (ADM), and tibialis anterior (TA) muscles. **Results:** A significant change was observed between the first and fourth years in CMAP values of the ADM muscle ($p=0.012$) in treated patients. In contrast, untreated patients experienced a significant reduction in mean CMAP values of the TA ($p=0.015$). Significant decreases in mean MUNIX values were found only in untreated patients, in the ADM ($p=0.022$) and TA ($p<0.001$). Treated patients experienced an average increase of 24.9 points in the MUNIX of the ADM ($p=0.024$) compared to non-treated patients. CMAP and MUNIX values for the TA muscle correlated with HFMSE scale results. **Conclusion:** The MUNIX values of ADM and TA muscles are biomarkers for disease progression in 5q-SMA types 3 and 4 over a four-year follow-up period. Despite a significant increase in ADM CMAP values among treated patients, only ADM MUNIX could identify motor unit loss in untreated patients. Furthermore, MUNIX values remained stable among treated patients over the four-year follow-up period.

Movement disorders in patients with systemic lupus erythematosus: cross-sectional study

Camilla Vanessa Araújo Soares[1], Tiago César Costa da Silva[1], Alessandra de Sousa Braz[2], Danielle Christinne Soares Egypto de Brito[2], Ana Karla Guedes de Melo[1], Adriana Meira Tiburtino Nepomuceno[1], Alex Tiburtino Meira[2]

[1]Universidade Federal da Paraíba, João Pessoa PB, Brazil.
[2]Universidade Federal da Paraíba, Departamento de Medicina Interna, João Pessoa PB, Brazil.

Correspondence: Camilla Vanessa Araújo Soares; Email: camilla.vanessa46@gmail.com.

Background: Systemic lupus erythematosus (SLE) is an autoimmune, multisystemic disease characterized by autoantibodies production and immune complexes deposition, triggering an multiorgan inflammatory process. Approximately 50% of patients with SLE develop neuropsychiatric symptoms, including movement disorders (MD). **Objective:** To investigate the prevalence of MD in patients with SLE, in a SLE outpatient clinic in a quaternary hospital in the state of Paraíba. **Methods:** This is a cross-sectional observational study, carried out in a quaternary hospital in the state of Paraíba between September 2023 and May 2024. Patients were selected at random from the SLE outpatient clinic. Seventy individuals fulfilled the inclusion criteria, which encompassed a confirmed diagnosis of SLE for a minimum duration of one year as per the American College of Rheumatology's standards. Additionally, participants were required to be 18 years of age or older and under regular monitoring by the Rheumatology team within the service. One patient was excluded due to a previous history of subarachnoid hemorrhage and two patients refused to be examined by a neurologist. **Results:** 67 patients were included in the final sample, the majority of whom were female (90%). The prevalence of neurological changes related to movement disorders detected on physical examination was 35.3% (n 24). No problems of coordination and balance were found. Action and postural tremor were the most prevalent (n 16; 23.5% of cases), probably secondary to hydroxychloroquine in 15 of them (mostly action worse than postural) and 1 case secondary to levothyroxine. Seven patients presented a discrete rigidity, although only 2 with bradykinesia. Only one patient presented spasticity. Despite being the well-known movement disorder associated with SLE, chorea was only found in 2 patients (2.9%), one presented generalized, including the hung-up knee jerk, and the other presented hemichorea. One patient presented myoclonic jerk movements on the foot, discrete and only with distraction (1.49%). Except for one patient within the tremor subgroup, the majority experienced mild tremors. No drug intervention was necessary in most cases, given the mild nature of the symptoms and their lack of impact on daily activities, except in two cases of parkinsonism and in one patient with hemichorea. One patient presented considerable exacerbation of essential tremor after the use of levothyroxine. **Conclusion:** MD has a prevalence higher than expected in patients with SLE (35.3%), with drug-induced tremor being the most prevalent, followed by chorea and parkinsonism. In light of this, it is imperative for healthcare professionals assisting these patients to recognize the presence of MD, enabling tailored management strategies to enhance their quality of life.

Moyamoya disease in a patient with previous bilateral carotid atherosclerosis and who underwent radiotherapy after breast cancer: a case with an uncommon evolution

Elvis Lucas Rabelo Shintay Chan[1]

[1]Universidade Federal de Ouro Preto, Ouro Preto MG, Brazil.

Correspondence: Elvis Lucas Rabelo Shintay Chan; Email: elvislucaschan2011@hotmail.com.

Case presentation: A 41-year-old pregnant woman receiving usual risk prenatal care is admitted to labor, which occurs uneventfully, on 01/26/2018. On the fifteenth day of the postpartum period, a sudden onset of paresthesia and hemiparesis in the right side began, but she did not seek medical attention because she thought the cause had been a "scare" and the symptoms resolved spontaneously. On 06/23/2019, he presented new hemiparesis in the right side, in addition to dysarthria with deviation of the lip commissure. The magnetic resonance imaging showed an ischemic stroke in the perirolandic regions

and left superior frontal gyrus, as well as marked thinning of the petrous and cavernous parts of the left internal carotid artery and prominence of the pericarotid leptomeningeal circulation ("ivy sign"), a pattern suggestive of Moyamoya disease. She was discharged, persisting only with grade IV hemiparesis and braquicrural on the right. On 12/17/2023 she presented a third ischemic event with worsening of hemiparesis and dysarthria, with computed tomography showing hypodensity in the high brain convexity bilaterally and in the left semi-oval center. She maintained sequelae of dysarthria, urinary incontinence and right crural monoparesis, having been approached by Neurosurgery only in 2024. **Discussion:** Moyamoya disease has a well-documented association with genetic factors, especially in Asian populations. Although the patient was not of Asian origin, she had a family history of stroke, but without further investigation. Otherwise, it is worth highlighting that there are a series of conditions associated with this pathology, such as trauma, meningitis and neoplasms, as well as two others that were present: atherosclerosis (which is bicarotid) and exposure to radiotherapy (the patient had a malignant neoplasm of breast in 2015). Regarding imaging exams, there are typical findings: stenosis in the final portion of the internal carotid artery; a collateral and dilated arterial network branching from the circle of Willis; and evidence of previous small cerebral infarcts. The age distribution of the incidence is bimodal, with a peak at 10 years old and the other at 40 years old. The diagnosis is often made after a stroke. However, the disease can progress with convulsions or remain asymptomatic. Surgical revascularization is indicated, but it depends on weighing risks and benefits. **Final comments:** Moyamoya disease, although low in incidence, is a pathology of great repercussions as it can lead to recurrent strokes, causing great harm to the individual. The importance of speed in investigation and treatment is essential to prevent new deficits. The genetic association makes it necessary to pay attention to neurological events in family members, which are often little investigated. Furthermore, this case demonstrates a possible late side effect of radiotherapy, which illustrates the importance of being aware of the association between neoplasms and strokes.

Moyamoya disease in early puerperium: a case report

Gabriel Abrahão Stoliar[1], César Minoru Toita Koga[1], Samia Talise El Horr de Moraes[1], Alexandre Henrique Scheibe[1], Alana Bacelar Limeira Sales[1], Talita Aparecida Conte[1], Gabriella Favero[1], Valéria Cristina Scavasine[1], Caio César Diniz Disserol[1,2,3]

[1]Universidade Federal do Paraná, Hospital de Clínicas, Curitiba PR, Brazil.
[2]Instituto de Neurologia de Curitiba, Curitiba PR, Brazil.
[3]Hospital Israelita Albert Einstein, São Paulo SP, Brazil.

Correspondence: Gabriel Abrahão Stoliar; Email: gabrielstoliar@gmail.com.

Case presentation: A 23-year-old female patient, born in Venezuela, on the 2nd day of postpartum post-vaginal delivery, presented with a sudden onset of right-sided hemiparesis and confusion, followed by a short-lasting focal epileptic seizure, progressing to refractory status epilepticus. Cranial magnetic resonance imaging demonstrated acute ischemia in both cerebral hemispheres. Cranial and cervical tomography angiography with occlusion of the intracranial portion of the internal carotid artery from the paraophthalmic segment with extensive collateral circulation and prominence of pial vessels, suggesting an appearance of Moyamoya syndrome. Cerebral angiography confirmed the findings. **Discussion:** Moyamoya syndrome is a cerebrovascular disorder associated with progressive stenosis of the internal carotid arteries and their proximal branches. As a result, an extensive network of collateral is developed. The main clinical manifestations are neurovascular injuries. Moyamoya is an angiopathy represented by Moyamoya disease and Moyamoya syndrome. It mainly affects people of Asian origin. It has incidence in 2 age groups (children aged 5 years and adults around 40 years old), affecting almost twice as many female patients as male patients. Approximately half of adult patients present with intracranial hemorrhage and half with ischemic complications. Pregnancy, including the prenatal, intrapartum and postpartum periods, is probably associated with the risk of hemorrhagic and ischemic stroke in women with Moyamoya disease, with the onset of the condition more frequently in the postpartum period, especially among 3 and 7 days after birth. On cerebral angiography, a distinct appearance characterized by stenosis of the distal intracranial internal carotid artery, extending to the proximal anterior and middle arteries. This stimulates a development of collateral vessels at the base of the skull, which have a "smoke breath" appearance (translating as moyamoya in Japanese) and are therefore called moyamoya vessels on cerebral angiography. **Final comments:** Moyamoya disease is a rare condition, but represents an important differential diagnosis of stroke in young people. Its neuroradiological characteristics are remarkable and its early identification can help in the management and prognosis of patients.

MS treatment in Brazil in 2022: medication dispensation by the public health system using big data

Alexandre Coelho Marques[1], Marina Martins Siqueira[1], Gabriely Rangel Pereira[1], Lucas Hernandes Corrêa[1], Victoria Lin[1], Luiz Eduardo Betti Paiva[1], Lívia Almeida Dutra[1]

[1]Faculdade Israelita de Ciências da Saúde Albert Einstein, São Paulo SP, Brazil.

Correspondence: Alexandre Coelho Marques; Email: acmarques.neuro@gmail.com.

Background: Multiple sclerosis (MS) is a chronic inflammatory disease. Within a decade of onset, about 50% of those who do not receive any treatment develop severe disabilities. Disease-modifying drugs (DMDs) prevent disabilities. Treatment modalities include escalation (starting with low-efficacy DMDs and escalating to high-efficacy DMDs) or initiating with high-efficacy drugs, which carry risks such as opportunistic infections and the need for infusion units. High-efficacy drugs like natalizumab and alemtuzumab are linked with better outcomes and are available through Brazil's Unified Health System (SUS), though they require administration at specialized centers. **Objective:** To describe the dispensation of MS medications by SUS in Brazil in 2022 and analyze regional differences. **Methods:** A retrospective, observational study using public databases from Data SUS was conducted to analyze patient demographics and MS medications dispensed. Data were extracted from the Authorization of Ambulatory Procedures (APAC) for MS drugs in 2022. All APACs dispensed in Brazil during this period were analyzed using a Big Data system for data extraction, processing, and modeling. **Results:** In 2022, 28,012 MS patients received treatment by SUS, with 72.4% being female. The regional distribution was as follows: Southeast (16,006 patients, 57%), South (5,840, 21%), Northeast (3,456, 12%), Midwest (2,230, 8%), and North (480, 2%). The highest patient prevalence was in the South (19.8 per 100,000 inhabitants), while the lowest was in the North (2.8 per 100,000 inhabitants). A total of 268,814 DMDs were dispensed, corresponding to the patient distribution across regions. There were 194 dispensation centers, with half of the states having only one center. Fingolimod, dimethyl fumarate, and interferons were the most dispensed drugs, at 22.3%, 20.2%, and 19.4% respectively. There were regional differences; interferons were predominantly dispensed in the North and Northeast, whereas natalizumab were most dispensed in three specific states (DF, CE, and SE). High-efficacy drug dispensations totaled 44,650 (16.6%), with alemtuzumab accounting for only 9 treatments. The median distances traveled by patients from their municipality of residence to the municipality of DMD dispensation were 84.2 km (±149.8) in the Midwest, 77.6 km (±253.2) in the North, 63.4 km (±113.7) in the South, 81.2 km (±232.0) in the Northeast, and 29.5 km (±70.4) in the Southeast. **Conclusion:** Patients with MS treated by SUS receive less high efficacy medications when compared to other countries. Most patients travel more than 100 km to receive medications, which could be a barrier to high efficacy medications. Regional differences highlight the need for greater attention to ensure equitable access to MS medication.

Mucormycosis as a cause of extrinsic eye musculation impact: rhino-cerebral form

Lorena Fernandes Kronbauer[1], Letícia de Barros Dias[1], Marcelo Simplicio Carvalho[1], Nathalye Fernanda Pedroso Dircksen[1], Mônica Meneguette Silveira[1], Bárbara Okabaiasse Luizeti[1], Damacio Ramon Kaimen Maciel

[1]Irmandade da Santa Casa de Londrina, Londrina PR, Brazil.

Correspondence: Lorena Fernandes Kronbauer; Email: lorenafkronbauer@gmail.com.

Case presentation: Male, 51 years old, 10 days after admission, right eye movement began with pain, of severe intensity, with a progressive decrease in visual acuity until reaching amaurosis, ptosis and ophthalmoplegia. There was weight loss of 12kg in 60 days. Previous pathologies: only diabetes mellitus. Ophthalmological examination: RE with papillary edema, macular hypopigmentation, fixed mydriasis, acuity without light perception or counting fingers. Magnetic Resonance Imaging of the orbits showed an infiltrative mass compromising the intraconal fat of the right orbit with slight contrast enhancement. Orbital tomography demonstrated a bulging nodular lesion in the left maxillary sinus, areas of bone discontinuity in the ethmoidal fovea and cribriform plate on the right, ethmoidal sinusopathy and mucous thickening of the right maxillary sinus. The patient underwent pulse therapy with corticosteroids, without clinical or radiological improvement. A biopsy of the right extraocular muscle was performed, with a positive result for mucormycosis. The patient was treated with Voriconazole and Amphotericin and referred to the responsible center for treatment of his pathology. **Discussion:** Mucormycosis is an infection caused by fungi from the Mucoraceae family - saprophytes often found in soil. Tissue invasion and rapid dissemination of the pathogen occurs in deep tissues, giving rise to an intense inflammatory process and tissue necrosis, especially in immunosuppressed patients. Epidemiology: affected age group is under 60 years old, but with more mortality in the elderly - 33.3%. Predominance of males, but with no significant difference in mortality between the sexes. Ocular symptoms, with edema and pain, are the most common symptoms, associated with paranasal sinuses involvement. Around 94% patients are diabetic. Patients who receive high doses of corticosteroids and when preceded by COVID-19 infection, have relatively higher mortality rates. The clinical forms: rhinocerebral, pulmonary, gastrointestinal, central nervous system (CNS), subcutaneous and disseminated form. The form of rhino-cerebral mucormycosis (RCM) is the most common of these forms and is subdivided into three types: rhino-maxillary, rhino-orbital and rhino-orbito-cerebral. Treatment must be aggressive, given its lethal nature, and involves treatment of the underlying cause (diabetes mellitus with or without diabetic ketoacidosis or neutropenia), appropriate antifungal

therapy, mainly with liposomal amphotericin B, and surgical debridement of the tissues involved. **Final comments:** Mucormycosis is a serious fungal infection, with classic involvement involving the sinuses, orbits and brain. Generally associated with immunosuppression, diabetes, and appears to have increased severity with recent COVID-19 infection. The most common form - rhinocerebral - was the one described in this case, with bilateral sinus involvement, but with involvement only of the ocular muscles on the right.

https://doi.org/10.5327/CBN241119

Multidimensional functional decline throughout Parkinson's disease development

Nathalia de Brito Pereira[1], Katia Cirilo Costa Nobrega[1], Isaíra Almeida Pereira da Silva Nascimento[1], Rafaela Pires Bocicovar[1], Carolina Gonçalves Santana[1], Letícia Rocha Matos[1], Fernando Fachine da Silva Fidelis[1], Luiza Mattos Aranha[1], Graziele Cardoso dos Santos[1], Maria Elisa Pimentel Piemonte[1]

[1]Universidade de São Paulo, São Paulo SP, Brazil.

Correspondence: Nathalia de Brito Pereira; Email: nathaliabpereira@usp.br.

Background: To manage diseases such as Parkinson's Disease (PD), guide new intervention frameworks and inform patients, it is important to identify the decline in different dimensions of functionality. The functionality analyzes the complex interaction among biological, psychological, and social factors, that is why it is one of the main health indicators. The World Health Organization based on International Classification of Functioning, Disability and Health (ICF), developed the World Health Organization Disability Assessment Schedule 2.0 (WHODAS 2.0), a generic assessment instrument to provide a method for measuring the impact of different health conditions in terms of functionality and disability across cultures. **Objective:** A cross-sectional study was carried out to measure how functional decline is associated with the progression of PD using WHODAS 2.0. Furthermore, a characterization of the participant functionality profile was made. **Methods:** There were 352 participants (55% male, 45% female), assessed with early to advanced PD (H&Y I-IV), aged between 35-85 years age, using dopaminergic medication and without other neurological disorders than PD. The instruments used were: the Telephone - Montreal Cognitive Assessment (T-MoCA), Movement Disorder Society – Unified Parkinson's Disease Rating Scale (MDS-UPDRS) Part I - II and WHODAS 2.0. **Results:** The descriptive analysis indicated that the most affected WHODAS 2.0 domains were domestic activities (ADL) representing 46% of the total score and subsequently mobility and participation representing 43% of the total score. The motor activities where participants found the most difficulties were: carrying out household tasks as quickly as possible (87%), getting dressed (74%), and getting up from a sitting position (71%). Furthermore, the time spent on healthcare and the emotional impact caused by the health condition also created difficulties for the participants, with 77% and 72% complaining respectively. In the Mobility, ADL, Self-Care and Participation domains, there is a significant difference between all H&Y stages confirmed by the post-hoc test. However, for the total scores of the Interpersonal Relationships, Cognition and ADLw (activities of daily living related to work and school) domains, there was no significant difference between H&Y I and II according to it. Besides that, a high positive correlation was found between WHODAS ADL with MDS-UPDRS I (R=0.53; p-value<0.00001) and MDS-UPDRS II (R=0.65; p-value<0.00001), WHODAS Self-Care and MDS-UPDRS II (R=0.82; p-value<0.00001), and between WHODAS 2.0 total scores and MDS-UPDRS I (R=0.67; p-value<0.00001) and MDS-UPDRS II (R=0.68; p-value<0.00001). A negative correlation was found between WHODAS 2.0 Cognition and T-MoCA (R=0.33; p-value<0.0001). **Conclusion:** Pharmacological and non pharmacological interventions should consider the clinical characterization of the different affected dimensions of functionality in people with PD.

Multifocal and longitudinal extensive transverse myelitis after Varicella zoster virus infection: a case report

Jessica Vaz de Melo[1], Lucas Alexandre Santos Marzano[1], Luiza Fontes e Souza[1], Giovanna Moraes Cardoso Oliveira[1], Luiz Felipe Lopes Campos[1], Vinícius Rezende Avelar[1], Mariana Figueiredo Miranda[1], Thiago Michael Ferreira Ibiapino[1], Pedro Henrique Dias Silva[1], Rodrigo Gonçalves Kleinpaul Vieira[1]

[1]Hospital Governador Israel Pinheiro, Belo Horizonte MG, Brazil.

Correspondence: Lucas Alexandre Santos Marzano; Email: lasmarzano@gmail.com.

Case presentation: We report an unusual case of transverse myelitis (TM) in a 65-year-old immunocompetent woman occurring two weeks after a varicella zoster virus (VZV) infection. The patient presented with painful vesicular eruption on her back involving the right T8-T10 dermatomes, consistent with VZV infection and started treatment with topical acyclovir. Two weeks later, she developed right inguinal paresthesia progressing to bilateral leg involvement, paraparesis and urinary retention. Upon admission, neurological exam revealed bilateral lower limb weakness graded 4 on the Medical Research Council. Sensory system examination indicated decreased pinprick, touch, temperature, joint position and vibration sensation below the T10 level bilaterally. Deep tendon reflexes were exaggerated at the knee and ankle joints. No further neurological abnormalities were observed. Cerebrospinal fluid analysis demonstrated elevated leukocyte counts with normal glucose and mildly elevated protein. Magnetic resonance imaging of the spine revealed hyperintense T2 lesions at C5-6 and T6-10 levels, the first one with gadolinium enhancement on T1 sequence. No lesions were identified in the brain or optic nerves. The patient was treated with intravenous acyclovir at 10 mg/kg every 8 hours for 14 days and methylprednisolone 1g every 8 hours for 5 days. Upon discharge, there was no immediate improvement in the neurological deficits, however, at one-month follow-up, significant improvement was noted in both motor strength and sensory function. **Discussion:** VZV is known to be responsible for a broad spectrum of neurological diseases, but TM is a rare and severe complication. It occurs in less than 1% of VZV reactivation situations and usually affects immunocompromised patients. It typically manifests days after the onset of the rash, although delayed presentations may occur even in the absence of active skin lesions. While there is usually a correlation between the dermatomal rash and the motor weakness, this is not always the case, and there may be a topographic dissociation in around 10% of cases. In our case, two peculiarities were observed: multifocal and longitudinally extensive spinal cord involvement. The pathogenesis of VZV-related TM is postulated to be related to direct viral invasion. Vascular and autoimmune mechanisms have also been proposed in its pathophysiology. Treatment strategies often involve intravenous acyclovir, corticosteroids and symptomatics. **Final comments:** This case underscores the importance of early recognition and comprehensive management strategies in improving outcomes for TM secondary to VZV infection. Early therapeutic intervention with acyclovir prevents multiplication and spread of the virus in the spinal cord contributing to good prognosis.For this reason, correct identification and early treatment are very important.

Multifocal motor neuropathy: a two-decade case report

Gabriel Belo Cavalcante Linhares[1], Samila Marissa Pinheiro Gomes[1], Aglagilson Fernandes das Chagas[1], Yasmin Luíse Lucena e Silva[1], Moisés Vasco de Freitas[1], Emanuela Maria de Aguiar Azevedo[1], Jonnathan Camara da Silva Vianna[1], Eduardo Martiniano de Lima[1]

[1]Universidade Federal Rural do Semi-Árido, Mossoró RN, Brazil.

Correspondence: Gabriel Belo Cavalcante Linhares; Email: gabriel.belo@alunos.ufersa.edu.br.

Case presentation: Multifocal motor neuropathy (MMN) is a rare autoimmune disease characterized by progressive and asymmetric muscle weakness due to conduction blocks in motor nerves. This report details a case initially diagnosed as Guillain-Barré Syndrome (GBS), but later identified as MMN following further testing. Patient A.J.G.X., a 51-year-old female, presented rapidly progressing tetraparesis with predominant right-side weakness in 2004. After treatment with human immunoglobulin and physiotherapy, she partially regained mobility, though significant improvement was not observed. In 2017, her symptoms worsened, peaking in 2021, after which she required assistance for walking and daily activities. Her family history includes an uncle with GBS. The patient, a former alcoholic, quit drinking five years ago. A neurological examination revealed grade IV strength in the upper limbs and proximal left lower limb, grade III in the proximal right lower limb, and grade 0 in bilateral plantar dorsiflexion. Patellar and Achilles reflexes were absent bilaterally. There was bilateral rigidity (1+/4+) and slight postural tremor in the lower limbs, with a resting tremor in the right hand. Imaging and neurophysiological tests indicated cerebellar tonsillar herniation (Chiari type I). In 2023, electromyography confirmed multifocal motor neuropathy with proximal motor conduction block in the bilateral median and ulnar nerves, and abolished motor potentials in the bilateral fibular nerves. After undergoing immunoglobulin therapy, consisting of three monthly sessions at a dose of 2g/kg intravenously each, the patient reported clinical stability but no significant improvement in weakness. She could walk with assistance only for short distances. She experienced occasional cramps and resting and kinetic tremors, especially in the right hand, with slight improvement. She currently attends motor physiotherapy twice a week. **Discussion:** MMN is a rare and diagnostically challenging condition. In this case, GBS was initially the main diagnosis. However, progressive motor deficits and lack of stabilization increased suspicion of MMN, confirmed by electromyography in 2023. This report underscores the need for heightened suspicion for pathologies that, despite initially resembling GBS, show continuous symptom progression. It is crucial for neurologists to consider MMN in the differential diagnosis of motor neuropathies with persistent progression to avoid treatment delays and improve patient outcomes. **Final comments:** This case highlights the complexity of differential diagnosis among progressive motor neuropathies, where MMN should be considered in patients with asymmetric and progressive motor weakness that does not stabilize. Understanding and differentiating MMN from other neuropathies is essential to avoid delays in diagnosis and improve patient prognosis, emphasizing the importance of detailed clinical evaluation and the judicious use of complementary tests.

Multifocal motor neuropathy: different clinical presentation of three cases

Danilo Marinho Pereira[1], Ana Marina Dutra Ferreira da Silva[1], Alessandra Lima Nogueira Tolentino[1], Igor Dias Brockhausen[1], Alzira Maria Siqueira de Carvalho[1]

[1]Faculdade de Medicina do ABC, Santo André SP, Brazil.

Correspondence: Danilo Marinho Pereira; Email: danilomarinho14@gmail.com.

Case presentation: We present three male patients with different manifestations of multifocal motor neuropathy. Patient 1: 56-year-old male with history of right upper limb weakness starting at age 31, progressing to weakness in both upper limbs over two years, followed by weakness in the lower limbs with a distal predominance after three years. Motor nerve conduction studies showed conduction block and uneven reduction in conduction velocity in all four limbs. Myography revealed positive sharp waves, fibrillations, and rarefaction of motor units' recruitment. Tests for GM1 antibodies were negative. Patient 2: 58-year-old male experiencing since the age of 45 weakness in the right lower limb, progressing within a year to bilateral weakness with drop feet. Nerve conduction studies indicated reduced motor conduction velocity in all four limbs with conduction block and no changes in the sensory conduction study. Myography showed fasciculations and rarefaction of motor units' recruitment. Patient 3: 58-year-old male with a seven-year history of distal weakness in the upper limbs, accompanied by cramps and pain. The first motor conduction study was unremarkable, and myography indicated chronic and acute denervation in four limbs compatible with motor neuron disease. After 01-year, the nerve conduction study was repeated in our service, showing motor conduction blocks, while sensory conduction remained normal. Myography during voluntary contraction indicated signs of chronic reinnervation in the proximal and distal muscles, with rarefaction of motor units in all four limbs. Complete exome sequencing revealed an alteration in the TTN gene variant chr2: 178,560,016 G>A, unrelated to the clinical findings. All three patients underwent treatment with intravenous human immunoglobulin and showed satisfactory symptom response. The treatment began at 25, 13, and 7 years after the onset of symptoms, respectively. **Discussion:** Multifocal motor neuropathy (MMN) is an uncommon, purely motor neuropathy characterized by asymmetric deficits with a preference for upper limb involvement. However, it is crucial to emphasize the importance of electrodiagnostic examination in the presence of atypical clinical presentations of the disease. **Final comments:** Multifocal motor neuropathy is a treatable condition. However, it is challenging to diagnose and can be confused with motor neuron disease (ALS and its variants). Hence, early diagnosis and treatment are crucial for improving the prognosis. It is important to note that symptom improvement may occur after many years of illness.

Correspondence: Heron Alves Vale; Email: heron_vale@hotmail.com.

Case presentation: A 50-year-old male patient was admitted to the neurology emergency department due to a sudden onset of motor and sensory deficit syndrome, associated with ataxia and dysphagia. His symptoms included: right ptosis, vertigo, vomiting, dysarthria, dysphonia, hypoesthesia in the right hemiface and left half of the body, peripheral pattern facial paralysis on the right, right hemiparesis, and hemiataxia. His medical history revealed hypertension, alcohol abuse, severe obesity, and smoking. He denied regular medication use. There was a positive family history of cardiovascular diseases, with his mother passing away at 52 years from acute myocardial infarction. Laboratory findings showed relative polycythemia (Hemoglobin 19.5g/dl). Cranial CT revealed hypodensity in the right cerebellar and lower bulbar regions. Angiotomography showed occlusion of the distal segment of the right vertebral artery and ipsilateral posterior inferior cerebellar artery. Further diagnostic assessment with MRI demonstrated multiple recent ischemic insults in the right caudate nucleus, right corona radiata, left centrum semiovale, and a subacute event in the right cerebellar hemisphere. **Discussion:** The array of clinical findings upon admission raised suspicion of Opalski syndrome, a rare manifestation of Wallenberg syndrome, characterized by ipsilateral hemiplegia/paresis with lateral bulbar syndrome. Wallenberg syndrome typically results from ischemic involvement of the arterial branches supplying the dorsolateral portion of the medulla, marked by ipsilateral limb ataxia, vertigo, vomiting, nystagmus, dysarthria, dysphonia, dysphagia, and possibly ipsilateral facial hypoalgesia, thermoanesthesia, and Horner syndrome. **Final comments:** The presentation of ipsilateral motor deficit associated with dorsolateral medullary syndrome suggests involvement of medullary penetrating arteries, branches of the vertebral artery supplying the pyramidal fibers post-decussation, potentially characterizing Opalski syndrome. However, the involvement of the facial nerve would not typically be explained by this syndrome. In this context, MRI is crucial for definitive diagnosis. In this case, confirmation of vascular territories and distinct chronologies suggests a possible thromboembolic etiology.

Multiple mononeuropathy in eosinophilic granulomatosis with polyangiitis: a case report

Manoela Moreira Guerreiro[1], Maria Fernanda Batalha Marques[1], Maria Eduarda Vieira Ribeiro Garcia[1], Elisa Fernandes Melo[1], Karolina Gouveia César Freitas[1]

[1]Universidade de Taubaté, Taubaté SP, Brazil.

Correspondence: Manoela Moreira Guerreiro; Email: manoelamguerreiro@gmail.com.

Case presentation: Male patient, 44 years old, asthmatic for 4 years, without other comorbidities, sought care reporting paresthesia in the left lower limb that began in the tibial region, extending to the foot. After two days, the symptom spread to the right lower limb and upper limbs, reporting loss of strength and allodynia in all four limbs. The condition was preceded by a fever of 38°C lasting two days, two bacterial pneumonias and two dengue fever events in the last 60 days. He was admitted to the nursery with an initial suspected diagnosis of Guillain-Barré Syndrome, but after being examined the syndromic condition became mononeuritis multiplex. Examinations showed hypereosinophilia (2,352), negative serology, unremarkable cerebrospinal fluid, non-reactive anti-cytoplasmic antibodies (ANCA), increased rheumatoid factor (16), negative ANA and increased ESR in the first hour (62). After three days, he continued to complain of decreased strength, paresthesia and allodynia. On physical examination, he presented diffuse subcrepitant rales on lung auscultation, multiple diffuse erythematous non-pruritic papules on his back, he was alert, oriented, without language and speech changes, with a mild paretic gait on the left, proximal grade IV strength in the lower limbs III/IV distal on the left and IV on the right, patellar, achilleus and styloradial reflexes were absent, vibratory hypoesthesia in the left lower limb, without other changes. The hypothesis of Eosinophilic Granulomatosis with Polyangiitis (EGPA) was considered based on signs, symptoms and late-onset asthma; thereforethe treatment was initiated with prednisone and cyclophosphamide. He was discharged after fourteen days of hospitalization, with improvement in lung auscultation and complaints of pain, reporting only maintenance of paresthesia. Continued on outpatient follow-up and electroneuromyography was performed, which showed diffuse and incipient impairment of peripheral sensory-motor nerve fibers, primarily axonal, asymmetrical and subacute, corroborating the clinical suspicion of vasculitis. DISCUSSION:It is very important to investigate rheumatological conditions such as EGPA in the presence of mononeuritis multiplex. EGPA belongs to the group of ANCA-associated vasculitis,although considered rare, it is the most common cause of neuropathy, characterized by the clinical triad asthma, hyper eosinophilia and systemic necrotizing vasculitis affecting small vessels. Peripheral neuropathy may be present in up to 72% of cases, expressed as multiple mononeuropathy or peripheral polyneuropathy. **Final comments:** This clinical case portrays the importance of early diagnosis of EGPA and the relevance of identifying peripheral nervous involvement in this process. Therefore, recognizing the clinical pattern of this type of peripheral neuropathy is essential for preventing comorbidities, reducing mortality, reducing neurological sequelae and consequently improving the patient's quality of life.

Multiple sclerosis (MS) and MOGAD familial cases share genetic variant rs118004742 in EFCAB13 previously associated as potential MS risk factor

Karla Pinto Coelho Fadel[1,2], Renan Amphilophio Fernandes[2,3], Elielson Veloso da Silva[2], Andreza Lemos Salvio[2], Jessica Raposo Vedovi[2], Larissa Araujo Duarte[2,3], Helena França Alcaraz Ferreira[2,3], Elisa Gouvea Gutman[2,3], Valéria Coelho Santa Rita Pereira[3], Soniza Vieira Alves-leon[2,3]

Genetic studies of CNS autoimmune diseases, such as multiple sclerosis (MS), and Myelin Oligodendrocyte Glycoprotein Antibody-Associated Disease (MOGAD) aim to identify genetic variants that influence disease susceptibility and progress. In this study, we performed whole-exome sequencing on a family with a history of MS and MOGAD. The proband, a 24-year-old male, presented with paresthesia on the left side of his upper and lower limbs. MRI revealed two hyperintense white matter lesions, one periventricular and one at the medullary bulb junction, both gadolinium-enhancing. Cerebrospinal fluid (CSF) examination showed oligoclonal bands with normal cell and protein counts and no serological or molecular evidence of infection, including SARS-CoV-2. Serum testing was positive for anti-MOG antibodies and negative for anti-AQP4 antibodies. Tests for other metabolic and autoimmune diseases were negative. Despite being asymptomatic, the patient tested positive for COVID-19 in serum and was treated with intravenous glucocorticoids, leading to complete recovery. The proband, diagnosed with MOGAD, and his mother, diagnosed with MS, were both found to be heterozygous for the rs118004742 (T>G) variant in the EFCAB13 gene. In contrast, his healthy father

and sister were homozygous for the reference allele. This variant, previously identified as potentially associated with MS susceptibility, introduces a premature stop codon at position 546 (p.Tyr546Ter), disrupting protein function and reducing EFCAB13 expression in various brain regions according to FIVEx and GTEx datasets. EFCAB13 encodes a protein with a calcium-binding domain essential for neuronal function and plasticity, suggesting that its reduced expression may contribute to MS pathogenesis, although the full function of this gene remains unknown. This familial pattern highlights the potential significance of the EFCAB13 variant in autoimmune conditions. Further investigation is warranted to better understand the role of EFCAB13 in MS and other autoimmune diseases, such as MOGAD, for which genetic risk factors are currently not widely explored. This finding reinforces the overlapping genetic aspects of CNS autoimmune diseases, offering insights into shared mechanisms of disease and potential cross-disease therapeutic approaches.

Multiple sclerosis and Behçet's disease: case report and literature review

Karina Carvalho Higa[1], Juliana Mathias Netto Khouri[1], Jussara Mathias Netto Khouri[1], Carlos Cesar Conrado Caggiano[1], Leandra Schneider[1], Isabela Louise Weber[1], Lucas Shigueo Hiromoto[1], Pedro Arhur Possan[1], Mateus Pinto Marchetti[1]

[1]Hospital Nossa Senhora das Graças, Curitiba PR, Brazil.

Correspondence: Karina Carvalho Higa; Email: karinacarvalho.fdc@gmail.com.

Case presentation: T.R.G, a 43-year-old female, has been diagnosed with antiphospholipid antibody syndrome (APS) and Behçet's disease (BD) since 2002. She was diagnosed with relapsing-remitting multiple sclerosis (MS) (EDSS 3) in 2019. The patient presents with left hemiparesis, optic neuritis, and hyperreflexic bladder. The MS diagnosis was confirmed by magnetic resonance imaging (MRI) showing multiple typical lesions and cerebrospinal fluid (CSF) analysis revealing oligoclonal bands. Previous treatments included beta-interferon 1a, glatiramer acetate, cyclophosphamide, dimethyl fumarate, and azathioprine, without favorable results. The patient is awaiting initiation of treatment with ofatumumab, an anti-CD20 therapy that may benefit both MS and BD. **Discussion:** The coexistence of MS and BD is rare and presents diagnostic and clinical management challenges. MS is an autoimmune disease of the central nervous system characterized by inflammation, demyelination, and neurodegeneration, resulting in varied neurological symptoms. BD is a systemic autoinflammatory disease with recurrent oral and genital ulcers, skin lesions, and rarely, central nervous system involvement. Differentiating MS from Neuro-BD (NBD) or primarily neurological BD (pNBD) is crucial, as each condition has specific diagnostic and therapeutic criteria. The McDonald criteria for MS require demyelinating lesions disseminated in space and time in the central nervous system, with findings on MRI and CSF. Patients with BD+MS tend to be women and exhibit a clinical course similar to MS, with relapses and remissions, unlike the progressive course of NBD or pNBD. This suggests that a personalized therapeutic approach, considering treatments for both conditions, may be beneficial. **Final comments:** A minority of patients with BD exhibit lesions similar to those in MS and meet the 2017 McDonald criteria. These BD+MS patients show clinical manifestations more aligned with MS than with NBD or pNBD, responding favorably to typical MS treatments. Findings suggest that patients with BD who present with MRI lesions, clinical characteristics, and CSF findings meeting the McDonald criteria should be treated considering both MS and BD. A multidisciplinary approach involving neurologists and rheumatologists is crucial for accurate diagnosis and appropriate management, aiming to provide the best treatment and quality of life for patients.

Multiple sclerosis and CIDP: navigating the challenges of coexistence

Filipe Brito Porto[1], Isabela Caldeira de Oliveira[1], Jéssica Semler de Sá Lima[1], Gabriella Corrêa Dousseau[1], Daniel Thomas Pereira Lopes[1], Arthur de Medeiros Dias[1], Maria Sheila Guimarães Rocha[1]

[1]Hospital Santa Marcelina, São Paulo SP, Brazil.

Correspondence: Gabriella Corrêa Dousseau; Email: gabrielladousseau@gmail.com.

Case presentation: A 65-year-old man with a prior diagnosis of primarily progressive multiple sclerosis at age 51 began experiencing tingling and numbness in his feet at age 58. Over several months, this progressed to significant difficulty in moving his feet, such as an inability to use the pedal when driving. Additionally, he reports noticing muscle flaccidity in previously spastic lower limbs. His neurological examination showed generalized hypotonia and muscular atrophy. Deep tendon reflexes were hypoactive in the upper limbs, patellar and achilleus reflexes were abolished, although there was a bilateral Babinski sign. There was a decrease in superficial sensitivity in the feet and a loss of vibratory sensation in the upper and lower limbs. An electroneuromyography examination was performed in which motor nerve conduction studies revealed a decrease in motor conduction velocities (>30% of the lower limit of normal) and prolonged distal motor latencies (>50%) in more than two nerves. Following targeted investigation, a diagnosis of overlapping CIDP was made. Treatment with intravenous methylprednisolone for 5 days a month over 6 months showed no measurable improvement. Subsequently, Rituximab was initiated, and the disease remained stable without further progression. **Discussion:** Multiple sclerosis is an inflammatory autoimmune demyelinating disease that affects the central nervous system (CNS) and may have a relapsing or progressive course. Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) is a peripheral autoimmune disease with also a relapsing or progressive course and in its classical form may cause symmetrical, proximal and distal, sensory-motor impairment, mainly in the lower limbs. Although the accidental occurrence of multiple sclerosis and CIPD or other polyneuropathies is possible, there is evidence that common antigens (e.g., Neurofascin 155, myelin basic protein, and myelin-associated glycoprotein) can trigger an autoimmune response in central and peripheral myelin proteins. Furthermore, considering combined central and peripheral demyelination as a distinct condition increases the need for specific treatment. Some previous studies have identified rituximab and alemtuzumab as possible treatments. **Final comments:** Therefore, given the importance of early recognition of clinical manifestations, a clinical case of CIDP in a patient with multiple sclerosis is presented below to improve the awareness of practicing neurologists for better treatment outcomes.

Multiple sclerosis and pregnancy: a relevant approach

Guilherme Vedovato Vilela de Salis[1], Gabriel Pina Paiva[1], Andressa Regina de Mello Galego[1], Renato Arantes Lima Simões[1], Waldir Antonio Maluf Tognola[1]

[1]Faculdade de Medicina de São José do Rio Preto, São José do Rio Preto SP, Brazil.

Correspondence: Guilherme Vedovato Vilela de Salis; Email: guilhermesalis@hotmail.com.

Case presentation: A 30 years old woman was diagnosed with RRMS in July 2001. For 3 years she had fluctuating multifocal neurological symptoms and the initial MRI showed multiple lesions suggesting demyelinating substrate with some of them showing contrast enhancement. During initial hospitalization she underwent corticosteroid therapy and plasmapheresis. After hospital discharge, Natalizumab (NTZ) was started with the patient reporting persistence of significant ataxia and asthenia. She underwent a total of 17 NTZ infusions, later abandoning treatment in January 2023. Therefore, she returned in April 2023 reporting worsening of the symptoms when MRI demonstrated areas suggesting inflammatory activity. She was subjected to a new corticosteroid therapy and presented remission of them. In November 2023, she discovered pregnancy and suspended the use of NTZ on her own, returning to emergency care in May 2024, 30 weeks pregnant, with a new outbreak, when MRI without contrast was compatible with previous exams but as a new outbreak was considered and pulse therapy was performed. There was symptomtic remission and she was discharged with pregnancy resolution 9 weeks later. The newborn was healthy and there were no new clinical outbreaks until the outpatient return in May 2024, when breastfeeding was suspended to resumption of NTZ. **Discussion:** The use of DMT, particularly NTZ, during pregnancy, lactation and its planning is a relevant issue in neurological practice and requires cleared neurological monitoring and discussion due to the lack of consistent data. The magnitude of risk of pregnancy-related MS relapses following NTZ cessation is unclear as whether this risk is reduced by pregnancy or other modifiable factors. Fetal morbidity and mortality associated with it and the joint decision regarding therapy should be an important factor in planning and approaching the patient. Our case illustrates a common and relevant clinical situation to the current state of the art of treatment of MS, considering the average age of prevalence of the disease. The inadvertent discontinuation of NTZ by the patient, motivated by her insecurity about the medicine and the lack of information regarding its use, resulted in 2 possible outbreaks within 3 years of her initial diagnosis, one of which was during pregnancy. Furthermore, the suspension of breastfeeding to resume use of DMTs is still a point of discussion in the literature. **Final comments:** The risk of new outbreaks of MS following the interruption of NTZ in the context of pregnancy planning, its implementation and breastfeeding must be discussed with the patient and considered in a broad context of possibilities so that the decision joint may benefit the patient in their treatment and reduce any fetal risks involved. The lack of information about this and the resulting patient's insecurity can increase the risks involved and be detrimental to the patient's clinical approach, depriving them of the best treatment

https://doi.org/10.5327/CBN241129

Multiple sclerosis and treatment with natalizumab in pregnancy

Rafael Bastos Delgado[1], Sandra Regina Alonso Gonçalves[1], Regina Maria Papais Alvarenga[1], Marina Papais Alvarenga[1], Lilian Bezerra do Nascimento[2]

[1]Universidade de Vassouras, Vassouras RJ, Brazil. [2]Hospital Federal da Lagoa, Rio de Janeiro RJ, Brazil.

Correspondence: Rafael Bastos Delgado; Email: 16rafaelbastos@gmail.com.

Case presentation: A 38-year-old patient, brown, lawyer with Relapsing-remitting Multiple Sclerosis diagnosed in 2009, using natalizumab (NTZ) since 08/2013, returns to the Reference Center for the treatment of Multiple Sclerosis, reporting that she has been pregnant with a gestational age of eight weeks. Although the routine care for pregnant MS patients was to suspend the use of disease-modifying drugs (DMD), in this patient, with a high lesion burden and already in the third month of pregnancy, it was decided by common agreement that the medication would be maintained. The last NTZ infusion occurred on 01/2018 (gestational age of 28 weeks, beginning of the 3rd trimester of gestation). On 24/03/2018, she

went into labor, giving birth to a baby girl weighing 2,300g 48cm long, by normal delivery after 38 weeks and four days of gestation. There were no relapses during pregnancy, only nausea and gestational diabetes. The daughter was born healthy and did not show any changes in the hematological tests and exams. The patient did not breastfeed her daughter and returned with the NTZ 15 days postpartum. NTZ was indicated due to the failure of glatiramer acetate and recombinant interferon-1a beta-to-control relapses. In 2013, with the worsening of disability after a new outbreak (EDSS = 6.0), the first infusion of NTZ was started, and since then, it has been stable (last follow-up on 03/2024). **Discussion:** Among the DMD, NTZ is the 4th line drug made available by the Unified Health System for the treatment of MS patients with high lesional burden after proven lack of efficacy in controlling relapses by immunomodulatory and oral drugs. It is a monoclonal antibody and has been approved since 2012 for RRMS. Its action is to prevent the migration of leukocytes to the brain, reducing the inflammation on the disease. Recent studies have shown that its use before conception or during pregnancy does not contribute to the increase in the rate of miscarriage, risk of malformations, and premature birth. Concerning newborns, low birth weight and hematological alterations have been identified when exposed to NTZ. However, it is challenging to abruptly discontinue the use of NTZ in pregnant MS patients as there is a high risk of rebound. **Final comments:** We report the case of a patient with Multiple Sclerosis and high lesion burden who, after becoming pregnant without planning, used NTZ during pregnancy without complications. Only this patient used NTZ during pregnancy in our referral center, where we have already followed more than a hundred cases of pregnant women in whom we suspended the use of these drugs until the puerperium. The British Consensus highlights the importance of discussions between patient and physician, presenting risks and benefits evidenced in studies, recommending the maintenance of natalizumab before conception, pregnancy, postpartum, and breastfeeding, and respecting the specificities found in each phase of the pregnancy-puerperal period.

https://doi.org/10.5327/CBN241130

Multiple sclerosis deaths in Brazil: a comparison between age groups and regions in the last 5 years

Izabelly Constatinov Lemos[1] , Gabriel Cordova[1], Emanuel Henrique dos Santos[1], Anne Beatriz Ricardo Amaral[1], Sofia Beatriz Andrade Manfio[1], Kauan Correia Derbli[1], Julia Farto Viana Oliveira[2], Gabriel André Silvério[1]

[1]Centro Universitário Campo Real, Guarapuava PR, Brazil.
[2]Universidade Estadual do Centro Oeste, Guarapuava PR Brazil.

Correspondence: Izabelly Constantinov Lemos; Email: med-izabellylemos@camporeal.edu.br.

Background: Multiple sclerosis (MS) is a neurological condition that affects the Central Nervous System, causing damage to the myelin and impairing the transmission of electrical impulses to the brain. It is believed that genetic susceptibility and environmental factors play a triggering role in the disease. Symptoms, including asthenia, paresthesia, weakness, dizziness, bladder dysfunction, and cognitive impairment, are variable and can manifest differently in each individual. **Objective:** To analyze the number of deaths related to MS in Brazil from 2019 to 2023, comparing age groups and regions. **Methods:** This observational epidemiological study used data from the Department of Epidemiological Analysis and Surveillance of Non-Communicable Diseases (DAENT) on deaths from MS (G35 multiple sclerosis) in Brazil between 2019 and 2023. Variables included age groups (from 0 to over 80 years) and regions (North, Northeast, Midwest, South, Southeast), excluding the unknown category. Deaths were categorized by residence, without distinction of sex and race. Results were compared to determine the most affected age groups and regions. **Results:** A total of 1329 deaths were recorded from 2019 to 2023. The highest number of deaths occurred in 2022 (n=325), and the lowest in 2023 (n=110). The most affected age groups were 60-69 years (highlighted in 2020, 2021, 2022) and 50-59 years (highlighted in 2019 and 2023). The Southeast region had the highest concentration of deaths, representing 48.9% of national cases. **Conclusion:** The Southeast and South regions were the most affected by MS deaths, possibly due to the genetic inheritance of European descent. The most affected age group was 60-69 years between 2019 and 2022, with a significant reduction in deaths in 2023 (64%). Further studies are needed to clarify etiological factors and improve treatment in different Brazilian regions.

Multiple sclerosis diagnostic delay in Brazil: related factors and the impact on functional outcome

Alex de Cerqueira Silveira Figueiredo[1], Maria Eduarda Messias Vassoler[1], Gabriel Souza Medrado Nunes[1], João Pedro Fernandes Gonçalves[1], Luana Araujo Passos[1], Luísa Dias Moreno Aravena[1], Júlia Xavier Oliveira[1], Bruno Bacellar Pedreira[2], Pedro Antonio Pereira de Jesus[1]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.
[2]Hospital Universitário Professor Edgard Santos, Salvador BA, Brazil.

Correspondence: Alex de Cerqueira Silveira Figueiredo; Email: alexcsf@ufba.br.

Background: Multiple sclerosis (MS) is a demyelinating disease marked by neurological deficits that are often disabling. Even with well-defined criteria, early diagnosis is a challenge worldwide. Knowing the factors related to late diagnosis enables timely recognition and treatment, allowing a better functional outcome. However, no studies yet investigated the factors associated with delayed diagnosis and its consequences in Brazil. **Objective:** To identify the factors associated with late diagnosis of MS in Brazil and its impact on functionality. **Methods:** A cross-sectional study was conducted with patients diagnosed with MS according to the McDonald criteria, followed up from July/2021 to April/2024 in a reference center in Bahia, Brazil. Clinical-demographic information was collected by interview and EDSS was defined after neurological examination performed by neurologists or neurology residents and was used to categorize functionality from symptom-free (0) to severe disability (≥5). Diagnosis after 3 months from symptom onset was considered late, following the NICE recommendation. Logistic regression was used to identify factors related to late diagnosis and ordinal logistic regression was performed to determine the impact of this delay on functionality. **Results:** 265 RRMS patients were recruited, of whom 178 (67.2%) were female. The median (IQR) age at symptom onset was 30 (22-38) and at diagnosis, 32 (24-40). One hundred and fifty-nine (60%) individuals were diagnosed more than 3 months after symptoms onset. The mean (SD) time from symptom onset to diagnosis was 24.1 (±43.1) months and the median (IQR) was 7 (2-29). Living outside the capital and metropolitan region (OR 2.477 [95%IC 1.382-4.439]), symptom onset before the 2017 McDonald criteria actualization (OR 2.090 [95%IC 1.134-3.607]), previous misdiagnosis (OR 2.057 [95%IC 1.131-3.743]) and presence of comorbidities (OR 2.925 [95%IC 1.639-5.222]) were the factors related to late diagnosis while first presentation with visual symptoms was related to early diagnosis (OR 0.522 [95%IC 0.292-0.933]). The delayed diagnosis was independently associated with worse functional outcomes (OR 1.724 [95%IC 1.086-2.737]) in a model adjusted for total relapse rate, disease duration, and age. **Conclusion:** There is still a lack of information on the delay in diagnosing MS in Brazil, and the time to diagnosis found in the present study is one of the longest ever reported in international literature. The majority of individuals with MS were diagnosed late and this was associated with difficult access to the health system, and pitfalls in the recognition and application of diagnostic criteria by both specialists and non-specialists. Finally, a longer time to diagnosis was related to worse functional outcomes, highlighting the importance of timely diagnosis and treatment for a favorable prognosis in MS patients.

https://doi.org/10.5327/CBN241132

Multiple sclerosis functional composite (MSFC) as a possible more sensitive tool for changes in functional evaluation than expanded disability status scale (EDSS) in multiple sclerosis (MS) patients: a Brazilian cohort study in Bahia

Maria Eduarda Messias Vassoler[1], Gabriel Souza Medrado Nunes[1], Alex de Cerqueira Silveira Figueiredo[1], Thaís Barbosa de Oliveira[1], Antônio Lázaro Santos Soares Junior[1], João Pedro Fernandes Gonçalves[1], Júlia Xavier Oliveira[1], Pedro Antonio Pereira de Jesus[2], Bruno Pedreira Bacellar[2], Thiago Gonçalves Fukuda[2]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.
[2]Hospital Universitário Professor Edgard Santos, Salvador BA, Brazil.

Correspondence: Maria Eduarda Messias Vassoler; Email: maria.vassoler@ufba.br.

Background: The multiple sclerosis functional composite (MSFC) is a tool used to assess functionality based on limb mobility and cognition in individuals with multiple sclerosis (MS). Periodic evaluation of functional capacity allows for monitoring disease progression. Although previous national studies have evaluated this tool, its sensibility has yet to be addressed, particularly in our heterogeneous population. **Objective:** To investigate the MSFC in evaluating variation in functional outcomes in patients with MS. **Methods:** This cohort study enrolled patients diagnosed with MS, according to the 2017 McDonald criteria, conducted between April 2023 and March 2024, that had no variation in the Expanded Disability Status Scale (EDSS) and no disease relapses between evaluations. Clinical and demographic information was collected through interviews at a reference center in Bahia. The EDSS was determined following a neurological examination performed by a neurologist, and the MSFC was administered by researchers at the same consultation. The MSFC consists of the Timed 25-Foot Walk (T25W), 9-Hole Peg Test (9HPT), and Paced Auditory Serial Addition Test (PASAT-3). We normalized the tests into Z-scores using the population mean established by the NMSS Task Force database and calculated the MSFC score. The Wilcoxon signed-rank test for dependent samples was performed. **Results:** The study comprised 85 patients, of whom 70.6% were female, with a median age of 40 years (IQR: 31.5-49). Within this cohort, 44.7% had completed high school education and 35.3% had higher education. The median duration of the disease was 6 years (IQR: 3-10), and the median follow-up time was 5 months (IQR: 4-6). The median EDSS evaluation in our sample was 1 (IQR: 0-4.75), while the median total Z-score of MSFC was -0.41 (IQR: -1.32-0.19) in the first evaluation and -0.20 (IQR: -1.34-0.28) in the second. When comparing the values of the different assessments with MSFC, a statistically significant difference was found ($p<0.05$). However, analyzing the components, T25W and PASAT-3 did not show a significant difference between evaluations ($p>0.05$), which was found in the different evaluations of the 9HPT ($p<0.001$). **Conclusion:** The MSFC is a tool that can possibly be more sensitive to small variations in the assessment of functional capacity in patients with MS when the EDSS evaluations do not vary. The 9HPT was identified as the test within the MSFC that showed the most significant differences between evaluations. More studies are needed to better understand the differences observed.

Multiple sclerosis in Brazil: an analysis of death and hospitalization trends using joinpoint regression

Alisson Rafael de Oliveira Pereira[1], Ana Júlia Alves de Oliveira Andrade[1], José Sidinei Rodrigues Dias[1], Rodrigo Ferreira de Moura[1]

[1]Universidade Federal de Lavras, Lavras MG, Brazil.

Correspondence: Alisson Rafael de Oliveira Pereira; Email: alissonropereira@gmail.com.

Background: Multiple sclerosis (MS) is one of the neurological diseases with guidelines described in SUS's Clinical Protocol and Therapeutic Guidelines (PCDTs). Although external factors may interfere, as it is a chronic noncommunicable disease without seasonality, trend variations in this type of time series can be more likely attributed to public policy interventions. **Objective:** To analyze joinpoints in the time series of deaths and hospitalizations due to MS in Brazil. **Methods:** A study was conducted using data recorded at the SIH using DATASUS. Time-series analysis was performed using a joinpoint model, and all PCDTs published on MS were reviewed. **Results:** Hospitalizations for MS varied annually with rates ranging from 0.85 (2010) to 3.39 (2021). The selected regression model suggested the presence of two joinpoints (WBIC= -3.29) and three bands of behavior in relation to the annual rates of change. In the first stretch, from 2008 to 2014, there was a non-significant increase (APC: 0.89; 95%CI: -9.69 to 5.84; p=0.91); in the second section, from 2014 to 2017, there was a considerable increase (APC: 27.5; 95%CI: 13 to 36.9; p<0.02); and in the third section, from 2017 to 2023, there was another increase, although less intense than the previous one (APC: 9.18; 95%CI: -5.37 to 12.76; p=0.12). During the study period, there was a significant increase in hospitalization for MS (AAPC: 8.72; 95%CI: -5.37 6.64; p<0.001). Regarding the death rate, joinpoints were not identified (APC: -1.24; 95%CI: -4.65, 2.28; p=0.44). As for Brazilian policies, the first PCDT for MS was instituted in 2010, guiding the use of β-interferon and glatiramer as 1st line of disease-modifying drugs (DMDs) and natalizumab in case of refractoriness. Updates to this plan were made in the following years: inclusion of fingolimod as DMD in 2014; mandatory monitoring of the 1st dose of fingolimod in a specialized center in 2015; inclusion of teriflunomide and dimethyl fumarate as DMD in 2018; Update of the McDonald criteria in 2019; possibility of plasmapheresis during outbreaks in 2021; and inclusion of alentezumab in high-activity RR-MS. The results of the ARIMA models (0,1,0) showed that the modification of the McDonald criteria in 2019 had a significant effect on deaths due to MS (B=0.014, SE=0.005; p<0.02), although the same analysis was not statistically significant for hospitalizations. **Conclusion:** Maintenance of the downward trend in MS deaths illustrates the effectiveness of therapies in preventing disease progression. An increase in MS hospitalizations was identified with joinpoints in 2014 and 2017. In both cases, the modification in the PCDT occurred in the year following the change in the trend. The need to monitor the administration of fingolimod may explain the increasing trend in hospitalizations that began in 2014, and the inclusion of teriflunomide and dimethyl fumarate in the PCDT may explain the decrease in the slope of this regression.

Multiple sclerosis resulting from the use of adalimumab for psoriatic arthritis

Fabricia dos Santos Almeida[1], Amanda Lima Sampaio[1], Lucas Medeiros Dunga[1], Artur Rebouças de Souza[1], Bianca Etelvina Santos de Oliveira[2], Iury Hélder Santos Dantas[1], Tiago Lameque de Sousa e Silva[1], Tereza Cristina Batista Dias[1], Matheus Procópio Guimarães[1], Helmut Kennedy Azevedo do Patrocínio[1]

[1]Universidade Federal do Rio Grande do Norte, Caicó RN, Brazil.
[2]Centro de Referência em Esclerose Múltipla na Paraíba, João Pessoa PB, Brazil.

Correspondence: Lucas Medeiros Dunga; Email: lucasdunga2000@gmail.com.

Case presentation: Female patient, 40 years old, diagnosed with psoriatic arthritis being treated with adalimumab (ADM). She developed paresthesia in her lower limbs, which was initially attributed to an anxiety disorder. After six months, there was a decrease in visual acuity in her left eye, and she was diagnosed with optic neuritis. She then underwent pulse therapy with methylprednisolone and began investigation for multiple sclerosis. She underwent a magnetic resonance imaging of the brain revealed several high signal density lesions in T2/FLAIR in both periventricular regions. In addition, imaging of the thoracic spine showed high signal intensity in the posterolateral cords at levels T5 to T9, these findings met McDonald's criteria. The neurological examination revealed mild paresis of the left lower limb, hyperreflexia in the lower limbs,mild hypopalesthesia in the right leg and bilateral plantar-cutaneous reflexes. Treatment with ADM was then suspended, and there were no more signs of psoriatic arthritis, except for a worsening of the skin condition. **Discussion:** The patient had an underlying autoimmune disease, psoriatic arthritis, one of whose treatments is the use of tumor necrosis factor (TNF) antagonists. However, one of the serious adverse effects of this type of medication is the risk of developing demyelinating diseases, such as multiple sclerosis. **Final comments:** Neurological disorders resulting from adverse effects of TNF, such as ADM, are rare, but should also be analyzed. And if these disorders occur during treatment, the drugs should be discontinued immediately.

Correspondence: Eduardo Mendonça Werneck da Silva; Email: eduardomwerneck@gmail.com.

Case presentation: In the present work we presente a 29-year-old male patient who presented with a pulsatile hemicranial headache with limitation to physical exertion, along with nausea, phonophobia, photophobia and analgesic refractoriness, due to such complaints he initiated investigation with a neurologist. The patient presented in his pathological history a previous event of cerebral venous thrombosis and recurrent genital and oral ulcers. In his Venous MRI, signs of extensive venous thrombosis of recent/subacute appearance were evident, affecting a large part of the superior sagittal dural sinuses, torcula of herophilus, straight sinus and transverse and sigmoid sinuses bilaterally, with extension to the bulbs of the jugular veins; In his CSF examination, no changes were found. **Discussion:** Neuro-Behçet is defined as the manifestation of neurological signs and/or symptoms in patients with a defined diagnosis of Behçet's disease, which can manifest itself in multiple ways, including multiple sclerosis syndrome, cerebral venous sinus thrombosis, meningoencephalitic syndrome or others, being subsequently divided into parenchymal or non-parenchymal forms depending on the brain involvement, the case in question being the non-parenchymal type. Presenting in its list of possible clinical changes symptoms, similar to idiopactic venous thrombosis, the patiet may experience headache, nausea, convulsions , focal deficits or even intracranial hypertension. **Final comments:** In cases with atypical epidemiology of cerebral venous thrombosis, investigation of possible secondary etiologies should be carried out with the aim of early diagnosis and thus avoiding new events and possible morbidity and mortality secondary to the underlying pathology.

[2]Hospital Universitário Gaffrée e Guinle, Rio de Janeiro RJ, Brazil.

Correspondence: Maria Eduarda Braz Ferreira Leão Caldas dos Santos; Email: meduardaleao@edu.unirio.br.

Case presentation: A 40-year-old female presented in 2010 a crisis of pain and burning sensation in the upper and lower limbs that worsened with temperature extremes, in addition to asthenia, abdominal pain, bilateral amaurosis for 1 week and a diarrhea episode that lasted 6 months. Two years later, she presented a case of hemiparesis. The complementary tests were performed for further investigation and the results were consistent with Fabry disease: genetic molecular testing showed the heterozygous mutation c.823delC in the sixth exon of the GLA gene and ophthalmological evaluation that identified cornea verticillata. Furthermore, laboratory tests showed microalbuminuria (55.54mcg/min) and proteinuria (0.19g/24h) in 24-hour urine collection and a brain MRI showed deposits of hemosiderin/ferritin in the right cerebellum hemisphere. Currently, our patient is on irregular betagalsidase enzyme replacement therapy, referring daily episodes of migraine with aura, frequent nausea, dysgeusia, worsening pain in her limbs and anemia. On current neurological evaluation, she presents monocular diplopia, painful hypoesthesia in hands and feet and touch hypoesthesia in feet consistent with superficial sensitivity syndrome compatible with polyneuropathy. **Discussion:** Fabry disease is a rare lysosomal deposition disorder linked to chromosome X, that affects the GLA gene. It's caused by a partial deficiency of the alpha galactosidase A enzyme, resulting in the excessive storage of globotriaosylceramide in the vascular endothelium and visceral tissue, which the skin, heart, kidney and the central nervous system are the most affected. Due to being a genetic inheritance linked to X chromosomal, every male patient with the genetic alteration manifests the disease symptoms. Otherwise, heterozygous female subjects may not present symptoms for a long while and, when manifested, these usually are less frequent and less intense. Therefore, this case warns of the occurrence of systemic manifestations in women, such as anemia, renal insufficiency, mood disorders, neuropathic pain and migraines, especially without the rightful treatment. **Final comments:** Fabry disease patients must join enzyme replacement therapy, since the treatment can halt disease progression, decreasing systemic manifestations. Thus, with early diagnosis and long-term adequate enzyme therapy, it is possible to guarantee the patient's well being.

Muscle ultrasound changes in pre-symptomatic and type 1 spinal muscular atrophy in the first months of life

Ana Lucila Moreira[1], Rodrigo Holanda Mendonca[2], Edmar Zanoteli[2], Raquel Diógenes Alencar Sindeaux[2]

[1]CENEC Neurofisiologia Clínica, Campinas SP, Brazil. [2]Universidade de São Paulo, Faculdade de Medicina, Hospital das Clínicas, São Paulo SP, Brazil.

Correspondence: Ana Lucila Moreira; Email: ana.lucila.moreira@gmail.com.

Background: Spinal muscular atrophy (SMA) is a life-threatening motor neuron disease and better outcomes are possible with both early diagnosis and treatment. **Objective:** We investigated the ultrasound pattern of muscle involvement in treated pre-symptomatic and type 1 SMA patients along the first months of life, to evaluate the evolution of muscle compromise secondary to the disease **Methods:** We examined longitudinally the biceps brachii, rectus femoris and intercostal muscles of three pre-symptomatic (2 copies of SMN2) and one type 1 SMA (2 copies of SMN2) patients diagnosed in the newborn screening, since the diagnosis (in the first month of life) along the first months of life (3-8 months), using B-mode ultrasound for mean grey scale analysis (GSA). All patients were initially treated with Risdiplam. **Results:** All patients had higher GSA in the rectus femoris compared to biceps brachii around the age of 3 months, even though in three of them the rectus femoris GSA was lower than the biceps brachii at the moment of diagnosis. In all but one patient the biceps brachii GSA increased in the first months of life. Three out of four patients had been followed of at least six months, showing stabilization of GSA in all studied muscles in two and continuous increase in one. **Conclusion:** Preliminary results of quantitative muscle ultrasound analysis in pre symptomatic and type 1 SMA patients demonstrated abnormalities in even clinically non symptomatic patients, and stabilization during the treatment. However, inclusion of more patients in the study and a longer follow-up period are necessary to obtain definitive conclusions.

Muscle ultrasound evaluation on congenital myasthenic syndrome related to CHRNE

Eduardo de Paula Estephan[1], Ana Lucila Moreira[1], Beatriz Carneiro Gondim Silva[1], André Macedo Serafim Silva[1], Antonio Alberto Zambon[1], Edmar Zanoteli[1]

[1]Universidade de São Paulo, Faculdade de Medicina, São Paulo SP, Brazil.

Correspondence: Eduardo de Paula Estephan; Email: eduardo.estephan@gmail.com.

The assessment of muscle disorders and myopathies is greatly enhanced by the addition of imaging to identify structural abnormalities and provide an assessment of muscle quality. In congenital myasthenic syndromes (CMS), muscle changes and their histopathological basis are not well understood. In fact, this issue has rarely been addressed. In one study with different types of CMS, no muscle alteration was found with magnetic resonance. In recent publication, myopathic changes on biopsy and magnetic resonance image have been reported, mainly in patients with CHRNE CMS. Muscle imaging showed at least mild alterations in the majority of confirmed cases, with preferential involvement of soleus, especially in CHRNE cases. However, muscle echogenicity in this disease group has not been evaluated. We qualitatively measured muscle echogenicity in patients with congenital myasthenic syndrome with receptor deficiency due to CHRNE mutations. Sixteen CHRNE patients were included. The patients' muscle echo intensity (IE) was classified as normal, mildly myopathic, moderately myopathic, or severely myopathic. Cranial, respiratory and unilateral appendicular muscles were evaluated. Fourteen patients had at least one altered muscle (87%). The most frequently affected muscles were: genioglossus (75%), lateral gastrocnemius (68%), tibialis (68%) and medial gastrocnemius (62%). Some distal muscle of the lower limb was altered in 81% of the patients. Among respiratory muscles, the external oblique was the most affected (56%). Surprisingly, the diaphragm was normal in all 16 cases, while intercostals were affected in 50%. On orbicular oculli, only five patients (35%) showed mild alteration. Other rarely affected muscles were: neck extensors (18%), geniohyoid (25%), internal oblique (31%) and digastric (37%). In all muscles, alterations were mild, except for 8 lateral gastrocnemius (50% of all cases), 6 medial gastrocnemius (37%), 4 tibial (25%) and 1 soleus (5%), on which moderate or even severe alterations were seen. In conclusion, complete normal muscle echogenicity is not common in CHRNE congenital myasthenic syndrome, being tongue and distal lower limb muscles the most affected. In the other hand, diaphragm is consistently spared among this population but intercostals can be affected. Then, muscle ultrasound may be useful to characterize this group of disease, and can be helpful to deeply identify the phenotype.

Music therapy as a complementary strategy for behavioral and cognitive enhances in dementia: a systematic review

Gabriel Thomaz Candido[1], Brener Raad Pereira[1], Caio Araujo de Souza[1], Carla Diovanna Spadine Pinhataro dos Santos[1], Gabrielle Gomes Garcia[1], Henrique Sarlo Pezzin[1], Marcus Vinicius Teixeira Calejon Stumpf[1], Matheus Guilherme Marques Vidal Barboza[1], Sofia Gameiro de Souza[1], Izabela Jardim Rodrigues Pitta[1]

[1]Universidade Federal Fluminense, Niterói RJ, Brazil.

Correspondence: Gabriel Thomaz Candido; Email: gabriel_candido@id.uff.br.

Background: The increasing prevalence of dementia, due to the rise in the population life expectancy, represents a public health and socioeconomic challenge, given the demands for individualized and multidisciplinary care. Music therapy, a practice that aims to promote the maintenance and improvement of physical, mental and emotional health through music stimuli, emerges as a non-invasive and complementary treatment alternative. The purpose of this systematic review is to evaluate musical practice as a tool, based on an analysis of the main findings in the literature. **Objective:** To provide evidence concerning the potential therapeutic role of music therapy in improving, behavioral and cognitive symptoms in elderly people with dementia diseases. **Methods:** This study is a literature review based on the methodological recommendations of the Preferred Reporting Items for Systematic Review (PRISMA) guidelines. The databases used were PubMed, SciELO, Cochrane and Lilacs. The search strategy was: music therapy OR song AND dementia AND elderly. The inclusion criteria were: randomized clinical trials, from 2014 to 2024, in English, covering the elderly population and meeting the objective of the study. The exclusion criteria were studies that used another non-pharmacological intervention simultaneously and studies not available in full version. **Results:** A total of 119 articles were found in the databases, with 14 duplicates. After double-blind screening, with a third evaluator to cases of disagreement, 25 were selected for analysis. Among these, 10 were excluded for not presenting results or for not being available in full version. The analysis of the 15 remaining articles showed a population aged 65 years or older, of both sexes and diagnoses with mild to very severe dementia. The type of therapeutic intervention varied between music listening, singing and choral singing. Nine articles, out of the 13 that analyzed behavioral issues, showed an improvement in patients` mood or a decrease in anxiety/agitation/depression. Six articles, out of eight that evaluated cognitive issues, showed an improvement in memory, executive functions or general cognitive functions. Among these, one article aimed to analyze the beta-amyloid levels and telomerase length, showing a slight increase in protein concentration and enhancement in cognitions and mood. In one article, lower keys increased patients` feelings of sadness, and faster rhythms increased their excitement. **Conclusion:** Music therapy has shown itself to be a possibility for the non-invasive treatment of symptoms related to cognitive and behavioral function, capable of improving patient's quality of life. Possible limitations of the studies analyzed relate to different etiologies of dementia diseases, which may respond differently to the therapy, the degree of dementia, that may influence the response to the proposed therapy and the variation in the music interventions, which can provide different results.

Mutation in the FHL1 gene and X-linked myopathy with postural muscle atrophy

Camilla Rocha Medeiros Pinho[1], Rafael Amaral de Matos Albuquerque[1], Guíniver Couto Almeida[1], Gabriel Negreiros de Camargo Martins Moreira[1], Marcela Câmara Machado Costa[1], Marilaine Matos de Menezes Ferreira[1], Adriele Ribeiro França Viriato[1], Thainá Gonçalves Tolentino de Figueiredo[1], Laís Brandão Mota[1], Luna Souza Silva Vilanova[1]

[1]Escola Bahiana de Medicina e Saúde Pública, Salvador BA, Brazil.

Correspondence: Rafael Amaral de Matos Albuquerque; Email: rafaelalbqq@outlook.com.

Case presentation: Consanguineous parents, first-degree cousins, had 8 children (2 females and 6 males) - 3 of the males died, two at 29 and 21 years (with similar histories). A.S.J., 21 years old, and L.S.J., 24 years old, children of the couple and patients at the outpatient clinic, began to manifest progressive muscle weakness at age 12, in the lower limbs and scapular-waist region. Both report episodes of falls and pain with physical exertion, as well as exertional dyspnea, requiring intermittent rests and non-invasive ventilatory support (biPAP). Gait in waddle, winged scapulae, and limited movements due to joint contractures are additional shared signs and symptoms. At 13 years old, A.S.J. presented severe right thoracolumbar scoliosis. Genetic testing identified a mutation in the FHL1 gene, with a suspected diagnosis of X-linked myopathy with postural muscle atrophy. **Discussion:** Both siblings present a complex clinical picture characterized by progressive muscle weakness, respiratory involvement, and cardiovascular changes, including structural cardiomyopathy with myocardial fibrosis. The mutation in the FHL1 gene that suggests a diagnosis of X-linked myopathy with postural muscle atrophy is a progressive condition with no known disease-modifying treatment, requiring multidisciplinary management involving neurologists, physiotherapists, and speech therapists to improve quality of life and delay disease progression. **Final comments:** This case report highlights the challenges in diagnosing and managing progressive myopathies, especially in families with complex genetic histories. Therapeutic approaches focused on respiratory support, muscle rehabilitation, and management of cardiac complications are crucial to minimize symptoms and improve the quality of life for these patients. Continuity in medical follow-up and adaptation of therapies as the disease progresses are essential to address the challenges faced by these patients throughout their lives.

https://doi.org/10.5327/CBN241141

Myasthenia gravis after hormonal blockade in a prostate cancer patient: case report

Pedro Vinicius Brito Alves[1], Riccardo Casarotti[1], Luiz Gustavo Brenneisen Santos[1], Aida Maria Negrão Esteves[1]

[1]Prevent Senior Brasil, São Paulo SP, Brazil.

Correspondence: Pedro Vinicius Brito Alves; Email: pvbalves@gmail.com.

Case presentation: A 66-year-old male was admitted with a history of bilateral asymmetric ptosis, complex ophtalmoparesis and head drop, with fluctuating symptoms, which began 3 weeks prior to admission and progressed to a myasthenic crisis. The patient had a previous medical history of multiple cardiovascular comorbidities and prostate adenocarcinoma with local lymph node invasion. Four weeks before the onset of symptoms, he received androgen deprivation therapy (ADT) with leuprorelin. Treatment with intravenous immunoglobulin therapy was started with substantial clinical improvement. Further investigation revealed a positive serum anti-acetylcholine receptor blocking antibodies and negative binding antibodies andnormal muscle enzyme levels. Chest imaging studies was unremarkable. He was diagnosed with myasthenia gravis based on clinical syndrome and antibody positivity. While his ocular and bulbar symptoms resolved, he still experienced fatigue and impaired axial support. He was referred to neuromuscular rehabilitation department and continues his oncological treatment without any other complications. **Discussion:** Myasthenia gravis (MG) is the most common neuromuscular junction disorder, with a bimodal prevalence, being more prevalent in young women and older men. Primary clinical manifestations include muscle weakness with fatigability, which can be explained by the saturation of a reduced number of acetylcholine receptors available on the postsynaptic membrane. MG produces autoantibody- and cell-mediated destruction of acetylcholine receptors (AChRs) at the neuromuscular junction of the skeletal muscles. Symptoms arise once the number of AChRs is reduced to approximately 30% of normal. Often known as a primary autoimmune disease, it may also occur in the context of active neoplasia, such as thymoma, which is frequently associated with anti-AchR receptor antibodies. There are rare case reports of myasthenia gravis associated with prostate cancer. Although androgen deprivation therapy is associated with a reduction in chronic inflammation and cancer progression, literature reports show patients developing myasthenia gravis during ADT. The detection of an atypical antibody and its response to immunotherapy suggest an immunological mechanism for the condition. However, the persistence of fatigue and generalized muscle weakness with absent muscle injury markers could be the caused by residual hypoandrogenism. **Final comments:** Oncological disease represent a major impact and has a increasing prevalence in the general population. This case emphasizes the importance of keeping high awareness of neurological complications related to cancer, as well as the adverse effects of oncological therapies. The association of disease activity and androgen deprivation medication may be a link between the state of functional hypogonadism in elderly men and development of MG. We highlight the role of the steroid hormonal system in modulating the immune system.

Myasthenia gravis as a hidden diagnosis in a patient with chronic pain syndrome and fatigue: a case report

Vanessa Conceição Saar Mautone Lima[1], Ricardo Cezare Araujo[1], Victória Nunes Alvares[2], Lucas Gonçalves Coelho[2], Clara Ribeiro Rizzo[2], Carlos Alberto de Souza Moreira[1], Mariana Gonçalves Musauer[1], Raphael Breder[1], Caroline Bittar Braune[1]

[1]Universidade Federal do Estado do Rio de Janeiro, Hospital Universitário Gaffrée e Guinle, Rio de Janeiro RJ, Brazil.
[2]Universidade Federal do Estado do Rio de Janeiro, Rio de Janeiro RJ, Brazil.

Correspondence: Victória Nunes Alvares; Email: victoriaalvares@edu.unirio.br.

Case presentation: A 20 year-old female presented with generalized myalgia and migratory arthritis following an acute episode of gastroenteritis. She reported progressive worsening of the pain and fatigue, associated with predominantly proximal muscle weakness, all of which worsend through the day and limited her daily activities. She was evaluated by the pain clinic, with a diagnosis of chronic pain syndrome, and was referred to our neurology department for further investigation. Severe pain greatly limited neurological assessment and interpretation of examination findings. The neurological examination demonstrated a slow gait, inability to walk on toes and heels, proximal appendicular weakness in upper and lower limbs, and complaint of fatigue during ocular motility evaluation, without ptosis and/or ophthalmoparesis. Complementary investigation included normal levels of creatine phosphokinase, aldolase and lactate dehydrogense, normal neurophysiological studies with repetitive nerve stimulation (acessory, ulnar and deep fibular nerves) and normal electromyography. Considering the possibility of generalized Myasthenia Gravis, the anti-acetylcholine receptor antibody level was requested, which was positive (3.41 nmol/L; negative <0.40nmol/L), thus confirming the diagnosis. **Discussion:** Myasthenia gravis (MG) is an autoimmune diasease of the neuromuscular junction mainly caused by anti-acetylcholine receptor antibodies (AChR). AChR-MG has typical bimodal age pattern, with a peak in young adults, as in the present case report, and then a steady increase in incidence with age older than 50 years. Muscle weakness is a major feature, and fatigability is a hallmark. Approximately 60% of patientes with MG have ptosis and/or diplopia at onset, but the absence of ocular findings should ot rule out the diagnosis, as ocurred in our case. Furthermore, symptoms related to chronic pain syndrome and proeminent fatigue obscured the clinical finding of muscle weakness in our case, reiterating the importance of having a high clinical suspicion for the diagnosis of MG in patientes complaining of predominantly proximal muscle weakness without defined etiology. Low-frequency repetitive nerve stimulation has sensitivity of 53-100% for the diagnosis of generalized MG, and accuracy is higher when weak muscles are evaluated. In forms of MG with proximal muscle weakness, the study of distal muscles of the limbs may be negative, which may have occured in our case. Single fiber eletromyography was not available on our institution by the time of her evaluation. **Final comments:** MG is a highly heterogeneous disease with different possible phenotypes. The absence of ocular findings should not exclude the diagnosis, and nonspecific findings such as fatigue are common, and can often obscure the identification of classic muscle weakness, thus delaying the diagnosis of a treatable disease.

https://doi.org/10.5327/CBN241143

Myasthenia gravis induced by immune checkpoint inhibitor

Alberto Pereira Firmino Filho[1], Maria Weryca de Souza Belo Silva[1], Mario Emilio Teixeira Dourado Junior[1], Miguel Inacio Silva Gomes[1], Felipe Toscano Lins de Menezes[1], Mario Teruo Yanagiura[1], Nathalia Lindsay Pereira de Queiroz[1], Francisco Gil Sarmento Neto[1], Felipe Olobardi Freire[1], Gabriel Soares Dutra de Souza[1]

[1]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil.

Correspondence: Alberto Pereira Firmino Filho; Email: firminofilho.ap@outlook.com.

Case presentation: 70 year-old male with unresectable multinodular hepatocellular carcinoma secondary to the hepatitis C virus, had been taking atezolizumab and bevacizumab every 3 weeks, starting in November 2023. In March 2024, he noticed diplopia and eyelid ptosis on the left, progressive in intensity, affecting the contralateral eye over the course of days. Symptoms fluctuated, worsening throughout the day and the side most affected varied as the day progressed. On physical examination, he presented a mild divergent strabismus, with slight limitation of eye movement in both the vertical and horizontal planes, unable to achieve convergence, associated with bilateral semiptosis. His pupils were small, but with correct photomotor response. Chronic bilateral hearing loss in use of hearing aid device. No change in appendicular assessment of strength, sensitivity or coordination. Fatigability tests did not increase strabismus or ptosis. Ice testing showed no improvement. Repetitive effort did not intensify strength or myotatic reflexes. Electroneuromyography was performed without evidence of decrement after repetitive low-frequency stimulation. Evaluated once again with concentric needle single-fiber electroneuromyography, the jitter analysis was suggestive of neuromuscular junction disease. Magnetic resonance imaging of the skull and CSF study showed no pathological findings. The patient was diagnosed with ocular Myasthenia Gravis, had atezolizumab suspended and started on prednisone associated with pyridostigmine. **Discussion:** Immune checkpoint inhibitors (ICIs), such as atezolizumab, have been increasingly used in clinical practice, with good effectiveness and tolerability, significantly improving the treatment prognosis, increasing survival and quality of life for users. However, in the follow-up of patients who use it, increased rates of side events related to autoimmunity were noted, including myasthenia gravis. Its occurrence has been reported in 1.2% of individuals who were exposed to treatment, with the majority of cases starting within the first 6 weeks of therapy. Two-thirds of cases are considered serious. Specific antibodies are negative in the vast majority of patients. Treatment involves the interruption of ICIs associated with immunotherapy, with corticosteroid therapy being the first choice. In refractory cases, human immunoglobulin or plasmapheresis are indicated. After improvement, selected patients can be treated with ICIs depending on the therapeutic need for the underlying disease, evaluating risk and benefits. **Final comments:** The use of ICIs is associated with autoimmune events, such as myasthenia gravis. Appropriate management includes temporary or permanent suspension of medication, which is only possible through early and accurate recognition of these possible associated complications.

https://doi.org/10.5327/CBN241144

Myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) mimicking a stroke: case report

Andreia Lira de Oliveira[1], Nise Alessandra de Carvalho Sousa[1], João Victor de Chagas Rossin[1]

[1]Universidade Federal do Amazonas, Manaus AM, Brazil.

Correspondence: Andreia Lira de Oliveira; Email: andreialira.med@gmail.com.

Case presentation: Woman, 53 years, presenting with an acute intense burning pain in her left arm, developing left hemiparesis over 15 minutes, resulting in a fall from her own height. After being taken to an Emergency Department, upon arrival she also noticed hypoesthesia on her left hemibody. The condition was treated as a stroke, and after ruling out intracranial hemorrhage, the patient underwent thrombolysis. After the procedure, she presented intense holocranial headache, which peaked in less than 1 minute. She was transferred to the intensive care unit, while maintaining neurological deficits and after 1 day, developed weakness in her right lower limb. Despite that, she was discharged from the hospital, returning

after 2 days due to persistent headache. A new cranial CT scan revealed subarachnoid hemorrhage and she was readmitted. Fifteen days after the onset of symptoms, she was transferred to a tertiary service, where neurological examination revealed flaccid paraplegia, associated with paresis in her left upper limb, along with areflexia in the lower limbs and left upper limb, with normal reflexes in her right upper limb. Regarding sensitivity, she presented anesthesia, hypoesthesia and anarthresthesia on her left hemibody up to C2 level, with preserved sensitivity on the right side. MRI of the skull, cervical and thoracic spine showed hyperintensity on T2/STIR sequences in the central region of the spinal cord, affecting from C2 to D3 level, with mild local mass effect and no contrast enhancement. Cerebrospinal fluid analysis revealed a cell count of 10cells/mm^3, 100% mononuclear cells, protein of 40g/dL and Glucose of 53mg/dL. Other tests did not show significant abnormalities. The patient received pulse therapy with methylprednisolone 1g/day for 2 days, which was suspended due to urinary tract infection. Two days after suspension of pulse therapy, she developed visual blurring in the right eye, prompting reintroduction of pulse therapy, completing a 7-day course. Subsequently, she underwent 7 sessions of plasmapheresis, resulting in partial improvement of strength in her left upper limb and sensitivity on her left hemibody. During treatment, her Anti-Aquaporin 4 antibody test was negative, while anti-mog was positive. She started maintenance therapy with Rituximab 1g every six months. **Discussion:** MOGAD is an autoimmune inflammatory disease associated with antibodies directed against a glycoprotein exclusive to the myelin sheath within the central nervous system (CNS). It presents with diverse clinical manifestations and typically shows significant response to corticosteroid therapy. The case described represents an atypical presentation of the disease, mimicking the presentation of a stroke in an emergency context. **Final comments:** It is necessary to consider the hypothesis of inflammatory CNS diseases in acute neurological contexts that present with atypical and recurrent symptoms.

Myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) with infectious trigger of neurosyphilis: case report

Camila Martins Soares[1], João Marcus de Lima Brito Alves[1], João Pedro Izidoro Gomes[1], Vanessa Lauanna Lima Silva[1], Charles Maroly Lessa Mantovani[1], Camila Aquino Cruz[1], Katharina Vieira Messias[1], Vanessa Daccach[1]

[1]Universidade de São Paulo, Faculdade de Medicina de Ribeirão Preto, Hospital das Clínicas, Ribeirão Preto SP, Brazil.

Correspondence: Camila Martins Soares; Email: camila.m.soares25@gmail.com.

Case presentation: Male, 57 years old, smoker, with amblyopia in the right eye (OD) and late latent syphilis treated with 3 doses of benzathine penicillin. He presented with left eye pain, temporal headache ipsilateral and progressive low visual acuity, initially 0.8 progressing in 10 days to counting-fingers at 4m. Proptosis was observed in the left eye (OS). On fundoscopy, pale optic nerve (ON), swelling of the left optic disc, with hyperemia and blurring of the disk margins, in addition to candle flame hemorrhages. Additional investigation showed black visual fields bilaterally, OCT with OD atrophy and edema of the retinal nerve fiber layer (OS). Laboratory results showed positive FTA-ABS and CSF with hyperproteinorrhaquia (52.4) and negative VDRL. Brain and orbits MRI with signs of optic neuritis on the left, highlighting perineuritis, as well as signs of right ON atrophy. Spine MRI showed no lesions. Therefore, treatment was initiated for neurosyphilis with ocular involvement with intravenous ceftriaxone 2g/d for 14 days and pulse therapy with methylpredisolone 1g/d for 5 days. After 8 days of starting treatment, the patient showed improvement in pain and visual acuity of OS of 0.7. However, 2 days later, he presented a new sudden visual loss and left eye pain, with finger-counting visual acuity in front of his face. A new pulse therapy was chosen, concomitant with plasmapheresis, with an improvement in visual acuity (0.5 in OS).The anti-MOG antibody (cell-based assay) test came back positive in the blood (1:10), confirming the diagnosis of myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD), with an infectious trigger of neurosyphilis being hypothesized. **Discussion:** Ocular syphilis is a clinical manifestation that can occur at any stage of the disease. It is known that some autoimmune diseases have an overlying infectious condition as trigger for the onset of the disease, as the MOGAD. There is another report of anti-MOG optic neuritis associated with neurosyphilis, in addition to other etiologies, such as HIV infection, SARS-COV-2 and CMV. It is known that MOGAD can present with atypical optic neuritis, transverse myelitis, acute disseminated encephalomyelitis and focal cortical lesions. Optic neuritis can present as perineuritis, making a differential diagnosis with other inflammatory optic neuropathies. However, incomplete response or recurrence after treatment of the infectious condition is an alert for an additional pathophysiological mechanism. **Final comments:** The association of neurosyphilis with MOGAD suggests it as a possible trigger, being the second case reported in the literature. The association of autoimmune diseases with infectious conditions must be remembered when faced with atypical progression, highlighting the importance of investigating differential diagnoses. In patients with neuritis and neurosyphilis, anti-MOG testing may be considered.

Myelitis as a paradoxical manifestation of tuberculosis in an immunocompetent patient

Jesângeli de Sousa Dias[1,2], Larissa Blanc Morais[2], Betânia Mara de Freitas Nogueira[2]

[1]Universidade Federal da Bahia, Salvador BA, Brazil.
[2]Secretaria de Saúde do Estado da Bahia, Instituto Couto Maia, Salvador BA, Brazil.

Correspondence: Jesângeli de Sousa Dias; Email: jesangelidias@gmail.com,

Case presentation: A 22-year-old immunocompetent woman was readmitted to the hospital complaining of acute bilateral leg weakness which began seven days earlier and progressed to complete paralysis within 48 hours associated with fecal and urinary retention, however without pain, fever, or trauma. Fifty days ago, she was diagnosed with disseminated tuberculosis including meningeal involvement which has improved after taking anti-tuberculosis drugs associated with prednisone (40mg/d). Of note is that the prednisone dose was gradually decreasing when symptoms began. The neurological examination showed a bilateral lower limb flaccid paralysis with normal patellar-deep tendon reflexes, but absent ankle-deep tendon reflexes. The sensitivity to pain and touch below a T8 level and a position sense in her feet were reduced. A thoracolumbar spine CT and CSF examination with the molecular test were normal. Previously, there was no abnormality on neurological examination, while a CSF study showed 30 cells/mm3 (86% neutrophils, 10% lymphocytes, and 4% monocytes), glucose 38mg/dL, protein 50mg/dL, and lactate 3,20 mmol/L. GeneXpert MTB/RIF detected M. tuberculosis in CSF and urine, also the bacteria grew in CSF culture. The tuberculosis treatment was continued, and prednisone was replaced by intravenous dexamethasone (16mg/day) without improvement. A thoracolumbar spine MRI spine performed 7 days after her admission showed edema and nodular lesions suggestive of granuloma inside the spinal cord at T8 and T12-L1 transition levels. After it, myelitis as a paradoxical reaction was confirmed and she was treated with an intravenous methylprednisolone (1 g/d) for three days. A few weeks later, the patient began to improve. She could walk without assistance and had better fecal and urinary control 8 months later. **Discussion:** The paradoxical reaction occurs during tuberculosis treatment. It results from an exaggerated host immune response to the mycobacterial antigen manifesting as worsening or appearance of new signs, symptoms, or radiographic manifestation of tuberculosis following a good response to the treatment. It appears between 2 weeks to 8 months after starting the medications, mainly within 12 weeks. Patients with tuberculous meningitis (TBM) are prone to this reaction, as well as those with high bacillary load. Corticosteroids used within the first 2 months to reduce TBM mortality, may prevent these complications. In this case, an early reduction of prednisone dose could trigger the reaction. Although reactions are treated with high corticosteroid doses, there is no definition of which treatment is best. A methylprednisolone pulse therapy was prescribed, and she improved. **Final comments:** Tuberculosis affects the nervous system in several ways, including paradoxical reactions. The diagnosis and treatment are challenging. Physicians should be aware of this manifestation, and that early diagnosis as well as appropriate treatment can prevent neurologic damage.

Myeloradiculitis from wasps swarm sting

Luis Fernando Guimarães[1], Osvaldo Pantoja de Oliveira[1], Adriane Paz Rocha[2], Jeferson Henrique Pereira[2], Marina Brasileiro Cesar Leitão[2], Bárbara Luisa Coraspe Gonçalves[1], Maria Luiza Levindo Coelho Martinis[1], Yasmin de Freitas Santos[1], Luiz Guilherme Gerhardt Fernandes[1]

[1]Hospital Federal dos Servidores do Estado, Rio de Janeiro RJ, Brazil.
[2]Universidade Estadual de Montes Claros, Montes Claros MG, Brazil.

Correspondence: Luis Fernando Guimarães; Email: luisguimaraesneuro@gmail.com.

Case presentation: A 53-year-old man, resident of a rural area, arrived at the emergency room with weakness in his lower limbs that had started two years ago. He reports that he was affected by numerous wasp bites on his lower limbs. He developed paraparesis and urinary retention hours later. It was necessary to use an indwelling urinary catheter. On physical examination: preserved tactile sensitivity, epicritic touch and impaired proprioception distally, in the lower limbs, worse on the right; paraparesis more evident in dorsiflexion (3/5 on the right and 2/5 on the left) and dorsoextension (4/5 on the right and 4/5 on the left); Achilles areflexia on the right. Complementary exams: magnetic resonance imaging (MRI) of the dorsal spine and skull; cerebrospinal fluid; tomography of the lumbar spine, abdomen and chest; electroneuromyography (ENMG); serology for syphilis, HIV, HTLV, hepatitis B and C, herpes simplex; research for ANA, Anti-Ro, anti-La and protein electrophoresis, Anti-MOG, Anti-Aquaporin-4; fecal parasitology (Kato-Katz) and rectal biopsy for research into schistosomiasis. Only MRI and ENMG showed changes. MRI of the dorsal column showed enlargement of the spinal cord in conus medullaris from D10 to L1 (hyposignal on T1, hypersignal on T2 and STIR), heterogeneous myeloradicular contrast enhancement, suggesting inflammatory-infectious disease. Brain MRI showed gliosis. ENMG showed acute axonopathy bilaterally, more evident on the left with L5 and S1 root involvement. The diagnosis of myeloradiculopathy resulting from wasp bites was confirmed. He received methylprednisolone, 1gram/day, for five days. The patient progressed with partial improvement of the paraparesis, but continued to require intermittent bladder catheterization. He is undergoing neurological monitoring. **Discussion:** Millions of cases of hornet bites occur every year around

the world. They are accompanied by local inflammatory reactions and, less frequently, by severe systemic reactions as a result of an IgE-mediated allergic reaction, which can lead to death. Anaphylaxis is a known consequence, but there are other unusual systemic reactions that can occur hours to weeks after stings. Among these uncommon reactions, we find neurological ones such as: myelitis, encephalitis, optic neuropathy, encephaloradiculoneuritis, cerebral infarction, acute inflammatory polyradiculopathy and axonal demyelination. We present the case of a patient diagnosed with myeloradiculitis secondary to wasp stings. **Final comments:** We emphasize the possibility of nervous system involvement in patients who have suffered wasp stings and, therefore, the main findings of the physical examination and complementary tests that, related to the clinical history, confirm the diagnostic hypothesis of wasp sting myeloradiculitis. Neurological changes in these cases are rare, little described in the literature and vary between affected individuals.

Myokines as biomarkers of severity and progression in spinal muscular atrophy

Ana Letícia Amorim de Albuquerque[1], Júlia Kersting Chadanowicz[1], Arthur Carpeggiani Weber[1], Giovanna Câmara Giudicelli[2], Marina Siebert[2], Thayne Woycinck Kowalski[2], Michele Michelin Becker[2], Jonas Alex Morales Saute[2]

[1]Universidade Federal do Rio Grande do Sul, Porto Alegre RS, Brazil.
[2]Hospital de Clínicas de Porto Alegre, Porto Alegre RS, Brazil.

Correspondence: Ana Letícia Amorim de Albuquerque; Email: analeticia.neurologia@gmail.com

Background: Spinal muscular atrophy (SMA) is a neurodegenerative disease characterized by progressive muscle atrophy and weakness due to the death of spinal cord motor neurons. The identification of biomarkers is essential for prognostic prediction and response to advanced specific therapies. **Objective:** Since muscle damage secondary to muscle denervation is one of the main clinical manifestations of SMA, we aimed to characterize the potential of myokines, myostatin, follistatin, and irisin as biomarkers. **Methods:** Differential gene expression of myokines was evaluated in a denervation lesion model of the gastrocnemius muscle in mice, as well as in a meta-analysis of RNA-seq datasets from three studies in Smn/;SMN2 SMA mice and two studies in SMA patients. Following this, a case-control study was conducted with 27 SMA patients and 27 controls, followed by a 12-month cohort study with the cases (n=25). Serum levels of myostatin, follistatin, and irisin were measured using enzyme-linked immunosorbent assay (ELISA). **Results:** Gene expression of myostatin and irisin was reduced, while follistatin was increased after muscle denervation in mice. The results were similar in the meta-analysis of the transgenic SMA mouse model and in the iliopsoas of 5 type 1 SMA patients. Consistent with these results, serum myostatin levels were markedly reduced in SMA patients, with a median of 98 (5-157) pg/mL compared to 412 (299-730) pg/mL in controls ($p<0.001$). Lower myostatin levels correlated with greater disease severity according to different clinician-rated outcomes (Rho=0.493-0.812; $p<0.05$). After 12 months, there was a further reduction in myostatin levels among cases ($p=0.021$). There was no statistically significant difference between cases and controls or correlation with severity variables in levels of follistatin or irisin. **Conclusion:** Serum myostatin level is a promising new biomarker for assessing the severity and progression of SMA. The reduction in myostatin levels and the consequent cellular environment favorable to muscle growth can be attributed to denervation-induced motor neuron dysfunction.

Mysterious case of subacute corticosteroid-dependent rhombencephalitis

Thire Baggio Machado Marazzi[1], Bruna Pereira Correia[1], Ellen Silva de Carvalho[1], Renato Ramon da Cruz[1], Soraia Fábio Ramos Cabette[1], Francisco Antonio Coletto[1], Raissa Gontijo Cabral de Souza[1], Gabriel Rosa Vilela[1]

[1]Hospital Unimed, Ribeirão Preto SP, Brazil.

Correspondence: Bruna Pereira Correia; Email: brunapereirac@hotmail.com.

Case presentation: A 67-year-old male from a rural area with no significant previous medical history was admitted to a tertiary care hospital with a 30-day history of progressive headache, vertigo, cerebellar ataxia, and diplopia. His brain MRI demonstrated diffuse leptomeningeal enhancement, an expanding lesion with hypersignal on T1/FLAIR affecting both cerebellar hemispheres, cerebral peduncles, mammillary bodies, and bilateral basal ganglia. CSF analysis showed 80 cells (98% lymphocytes), 113 protein glucose 67, cultures, and direct testing for bacteria and fungi were harmful. A hypothesis of rhombencephalitis associated with chronic meningitis was suggested, and the patient underwent treatment with ampicillin and ceftriaxone for 21 days, with slight clinical improvement and expansion of the 4th ventricle. Approximately 45 days after the onset of symptoms, the patient developed uncontrollable vomiting with signs of decompensated intracranial hypertension. Corticotherapy was started with excellent clinical response. Investigations were expanded to include multiple fungal serologies, CSF FilmArray® Meningitis/Encephalitis (ME) Panel and metagenomic next-generation sequencing (mNGS), all negative. A search for a hidden neoplasm was carried out using serial images and markers, and a PET CT was completed without significant findings. Brain biopsy was considered high-risk and contraindicated. Approximately four months after the onset of symptoms, the patient developed a progressively worsening headache and bilateral papillary edema. New CSF demonstrated increased opening pressure (40 mmHg, all previously normal) and positive latex agglutination for fungi with an antigen titer of 1:1280. Definitive treatment was performed with liposomal amphotericin, highlighting the immense challenges in diagnosing and treating this rare case. **Discussion:** This report presents a unique and challenging case of neurocryptococcosis in an immunocompetent patient. Despite high-accuracy tests, the infectious agent was only detected in the CSF after immunosuppression induced by corticosteroid therapy. This highlights the complexity and challenges in diagnosing such cases and the need for further research in this area. Previous literature reports of false negatives with film array and metagenomics have already been described but are scarce. **Final comments:** Although this report was developed with an immunocompetent patient, an infectious agent was only detected in CSF after immunosuppression induced by corticosteroid therapy. Despite being highly accurate, we must underline the potential for false negatives in molecular tests, a crucial point for further research and caution in similar cases.

[2]Universidade Federal de Pernambuco, Recife PE, Brazil.
[3]Universidade de Pernambuco, Recife PE, Brazil.

Correspondence: Evelliny Gomes da Silva; Email: evellinygomes1@hotmail.com.

Case presentation: A 20-year-old woman reported excessive sleepiness, being confined to bed most of the time and dependent on others to carry out daily activities. She was initially diagnosed with a mood disorder and treated with lithium carbonate, with no significant improvement in her condition. After about 6 months, she began to lose her visual acuity and was admitted to a neurology ward for further investigation. On admission, she had bilateral visual acuity of 20/200, pallor of the optic papillae on fundoscopy, isophotoreagent pupils and no relative afferent pupillary defect. During the anamnesis and physical examination, it was noted that the patient suddenly had episodes in which she appeared to fall into deep sleep. No other alterations were found on physical examination. Magnetic resonance imaging revealed bilateral sequelae of gliotic lesions in the paramedian region of the thalamus, with apparent extension to the posterior hypothalamus and an impression of optic nerve blurring on the left. In view of the suspicion of neuromyelitis optica spectrum disease, a positive anti-AQ4 test was requested. The patient was started on modafinil 100 mg/day to control sleepiness and rituximab, with guidance on laboratory follow-up. At the outpatient clinic, the patient reported an improvement in sudden sleep episodes and no new outbreaks of the disease. **Discussion:** Narcolepsy is a clinical syndrome characterized by excessive daytime sleepiness with cataplexy. Its cause may be related to the loss of orexin signaling, produced in the lateral hypothalamus, whose excitatory effects are important for maintaining wakefulness. Genetic factors and rare brain lesions can also cause the disease. As it has a non-specific clinical course, it is commonly diagnosed as a mood disorder or functional disorder, which is detrimental to the individual living with the disease. Neuromyelitis optica (NMO) and narcolepsy are two distinct diseases, but both can manifest with unusual clinical phenotypes, which creates several challenges in diagnosis and treatment. The discovery of the anti-aquaporin-4 (AQP4) antibody in patients with NMO has transformed the understanding of the disease, allowing the identification of cases beyond the traditional phenotype. These patients can exhibit a wide range of neurological symptoms, including narcolepsy associated with hypothalamic lesions. Early detection of patients with atypical presentations of NMO and narcolepsy is essential in order to start treatment quickly, with the aim of reducing disability and preventing further attacks. This underscores the importance of a thorough investigation of neurological symptoms and complementary tests for an accurate diagnosis and effective clinical management of these conditions. **Final comments:** It is important to consider differential diagnoses in patients with atypical neurological symptoms, such as excessive daytime sleepiness and loss of visual acuity.

NCSE in the elderly: clinical-EEG variables and prognosis at 30 days according to acute and remote etiology

Gloria M. A. S. Tedrus[1], Rodrigo Barros de Pádua Andrade[1], Bruno Ferreira Faria[1]

[1]Pontifícia Universidade Católica de Campinas, Campinas SP, Brazil.

Correspondence: Gloria M. A. S. Tedrus; Email: gmtedrus@uol.com.br.

Background: In the elderly, nonconvulsive status epilepticus (NCSE) is frequent, however there are still gaps in knowledge about the types of presentation, ictal EEG patterns and prognosis. It is questioned whether the prognosis is related to the etiological factor. **Objective:**

To evaluate the prognosis and clinical-EEG variables in older adults with NCSE according to remote or primary acute etiology. **Methods:** Clinical-EEG data and the occurrence of death at 30 days in 90 elderly patients diagnosed with NCSE of structural etiology (primary acute or remote) treated at the clinical neurology service of the PUC-Campinas Hospital were evaluated and compared. **Results:** The mean age was 72.6±8.3 years and 57(63.3%) cases were female, 53(58.9%) cases had acute etiology and 37(41.1%) had remote etiology. The NCSE type was - NCSE-coma in 41(45.6%) cases and NCSE-without coma in 49(54.4%) cases. No significant difference was observed in gender and age according to the type of etiology. There was no difference in the ictal EEG pattern (Salzburg Criterion - A1, A2, A3, A4) according to acute or remote etiology. Death within 30 days occurred in 32(35.6%) cases, with no difference according to etiology. Previous history of seizures/epilepsy occurred more and significantly in older adults with NCSE of remote etiology (Fisher's exact test, 6(11.3%) vs 17(45.9%), p< 0.000). There was a difference in the type of NCSE according to the etiology, with a higher occurrence of NCSE-coma in cases with acute etiology (chi-square test; 30 vs 11, p=0.012). **Conclusion:** In the elderly with NCSE, there were differences in the clinical variables according to the acute/remote etiology. Previous history of seizures/epilepsy occurred more frequently in the NCSE of remote etiology, and the clinical presentation of coma was more frequent in the elderly with NCSE of acute etiology. Mortality in this sample was high, with no difference according to acute/remote etiology in elderly patients with NCSE. FAPESP 2023/01226-4.

Needle electromyography in patients with amyotrophic lateral sclerosis: a cohort with 81 patients

João Vítor Ribeiro dos Santos[1], Rômulo Cerqueira Heckert dos Santos[1], Salim Lázaro Balassiano[1], Eduardo Rodrigues Davidovich[1], Robson Teixeira Vital[1], Clarissa Neves Spitz[1], Larissa Bittencourt de Carvalho Chaffin[1], Livia de Almeida Afonso Abihaila[1], Isadora Versiani de Lemos[1], Marcia Rodrigues Jardim[1]

[1]Hospital Universitário Pedro Ernesto, Rio de Janeiro RJ, Brazil.

Correspondence: João Vítor Ribeiro dos Santos; Email: jvriber@gmail.com.

Background: ALS represents the main entity within the group of Motor Neuron Diseases (MND). It is characterized by the progressive, painless degeneration of the first and second motor neurons. It is a disease that imposes a significant burden of morbidity and mortality on patients. Therefore, it is important to have tools that assist not only in the diagnosis but also in the prognosis of these patients. The diagnosis of ALS is based on clinical findings, however the neurophysiological study can support the diagnosis when it is not defined by the clinic. Furthermore, the neurophysiological study is an important tool for the differential diagnosis of ALS. **Objective:** To demonstrate the neurophysiological findings of patients diagnosed with ALS (Amyotrophic Lateral Sclerosis) at the Pedro Ernesto University Hospital. **Methods:** Eigthy one patients were diagnosed with ALS (Revised El Escorial Criteria). Patients with comorbidities that lead to Peripheral Nervous System impairment or Central Nervous System diseases were excluded. The criteria analyzed were: 1) fibrillations and positive sharp waves; 2) fasciculations; 3) signs of chronic axonal loss. The findings were topographically mapped in the following segments: 1) cervical; 2) thoracic; 3) lumbar; 4) bulbar. The patients were classified according to the El Escorial criteria: 1) Suspected; 2) Possible; 3) Probable; and 4) Definite. **Results:** 81 patients, findings were present in 1 segment in 5% (4) of patients; in 2 segments in 25% (20) of patients; in 3 segments in 32% (26) of patients; and in 4 segments in 36% (29) of patients. Among the patients with definite ALS, 3% showed alterations in 1 segment, 20% in 2 segments, 28% in 3 segments, and 50% in 4 segments. For those with probable ALS, 18% had neurophysiological findings in 2 segments, 73% in 3 segments, and 9% in 4 segments. Patients classified as having possible ALS showed a wider range of results 11% had normal exams, 22% had alterations in 2 segments, 33% in 3 segments, and another 33% in 4 segments. Finally, among the 21 patients with suspected ALS, 5% had normal exams, 14% showed alterations in only one segment, 38% had two segments affected, and 24% had findings in all four segments. In cases with suspected ALS, 43% of patients had findings in 3 or 4 segments. In patients with possible ALS, 66% of patients (2/3) have findings in 3 or 4 segments. Chronic denervation (long polyphasic motor unit potentials with or without large amplitude and neurogenic recruitment) were found in 91% of the total 81 patients studied. Membrane instability findings as acute fibrillations / positive sharp waves, and fasciculations were observed in 68% and 63%, respectively. **Conclusion:** The findings from the neurophysiological study of patients with ALS can be a tool to increase the safety of diagnosing a disease that has a poor prognosis. Furthermore, these findings allow us to propose future studies to evaluate the loss of motor units in patients with ALS.

https://doi.org/10.5327/CBN241153

Nephrogenic diabetes insipidus following carbamazepine withdrawal in the treatment of epilepsy: case report

Isabela de Carvalho Florêncio[1], Rodrigo Ibañez Tiago[2], Carolina Cândida Vaz[1], Rodolfo Antonio Corona[1], Mateus Magalhães Barbosa[1], Renata Gratão Rezende[1], Guilherme Augusto de Oliveira Soares[1], Gabriel Pereira Braga[1], Elder Yamazane Oda[1]

[1]Hospital Universitário Maria Aparecida Pedrossian, Campo Grande MS, Brazil.
[2]Universidade Federal de Mato Grosso do Sul, Faculdade de Medicina, Campo Grande MS, Brazil.

Correspondence: Rodrigo Ibañez Tiago; Email: rodrigoibaneztiago@gmail.com.

Case presentation: A 60-year-old woman, on carbamazepine for 49 years due to focal epilepsy, was admitted to the emergency department because of refractory status epilepticus, requiring sedation, analgesia, and orotracheal intubation. The accompanying person reported that the medication had been discontinued a week prior and valproic acid initiated without apparent reasons. Following medication cessation, she began experiencing daily episodes, escalating to a bihemispheric tonic-clonic seizure lasting over 30 minutes on the day of admission. Brain tomography showed no abnormalities. EEG post-sedation did not reveal electrographic status epilepticus. She developed right-sided bronchoaspirative pneumonia, treated with piperacillin and tazobactam. During weaning off mechanical ventilation and sedation, she developed polyuria (maximum urine output 10,200 mL/24h) associated with refractory hypernatremia and hypokalemia. Nephrogenic Diabetes Insipidus (NDI) was diagnosed, resolving upon carbamazepine reintroduction. She was discharged after 11 days of hospitalization. **Discussion:** NDI is a rare condition characterized by an inadequate response to vasopressin, resulting in the kidneys' inability to concentrate urine and subsequent electrolyte disturbances. Carbamazepine-induced hyponatremia is common due to upregulation of vasopressin V2 receptors (V2R) in the collecting duct and consequent upregulation of aquaporin 2 (AQP2), which is why it can be used in the treatment of Diabetes Insipidus. Abrupt withdrawal of the medication may have disrupted homeostasis, reducing V2R and AQP2 expression. To the best of our knowledge, there are no reports of NDI caused by this medication discontinuation. **Final comments:** The presented case illustrates a rare and potentially serious complication associated with prolonged use and inadequate management of carbamazepine. Early diagnosis and medication reintroduction were essential for resolving the patient's clinical condition. Attention to the adverse effects of antiepileptic medications is crucial for the effective and safe management of patients with long-standing epilepsy.

Nervous system tuberculosis in Bahia and Brazil: an ecological study

Fabrício Rodrigues Barbosa[1], Ester Costa Lima[1], Victor Alex Purificação de Castro Neves[1], Lucas Granja Kaupert[1], Paula Cely da Silva Torres[1], Paulo Vitor Silva Santos[1], Jéssica de Andrade Ribeiro Lima[1], Karollyne de Castro Santos[1], Bruna Rafaela Bastos Freire Quixabeira[1], Alexandre David do Nascimento Santos[1]

[1]Universidade do Estado da Bahia, Salvador BA, Brazil.

Correspondence: Ester Costa Lima; Email: ester.enfe@gmail.com.

Background: Tuberculosis (TB) is a serious public health problem, especially in developing countries. Although it mainly affects the lungs, TB can spread to the Central Nervous System (CNS), resulting in neurotuberculosis, a severe form of extrapulmonary TB. This condition causes sensory and motor deficits, seizures, and cognitive changes. Understanding the epidemiological profile of hospitalizations and deaths due to neurotuberculosis is crucial for early diagnosis and prevention of permanent neurological damage. **Objective:** To compare the epidemiological profile of hospitalizations and deaths due to tuberculosis in the nervous system in Brazil and Bahia from 2013 to 2023. **Methods:** This ecological, retrospective, cross-sectional, descriptive study used data from the Hospital Admission System (SIH/SUS-DATASUS) from 2013 to 2023. ICD-10 codes were used to select data on total costs, hospitalizations, and deaths by sex, color/race, and age group in Brazil and Bahia. Data analysis was performed using Microsoft Office Excel® 2016. **Results:** From 2013 to 2023, Brazil spent R$7,323,229.72 on CNS TB hospitalizations, with Bahia accounting for 4.8% of this. The average length of hospital stay in Brazil was 15.9 days, higher for women (16.2) than men (15.7). Mixed-race individuals had the longest stays (16.4 days), and indigenous people the shortest (8 days). In Bahia, the average stay was 17.5 days, with women averaging 18.2 days and black individuals 19.3 days, while white individuals had the shortest stay (5 days). The mortality rate in Brazil for CNS TB was 10.92 deaths per 100,000 inhabitants. Evaluating by age group, the rate increased with each decade above 40 years: 40-49, 11.34; 50-59, 12.15; 60-69, 13.24; 70-79, 24.55; and over 80, 28.95. In Bahia, the mortality rate was lower than the national average (10.46), but the increasing trend with age was maintained: 30-39 years, 13.04; 50-59 years, 21.05; and 70-79 years, 33.33. No data were available for those under 15. Nationally, female mortality was higher (11.10/100,000) compared to males, while in Bahia, male rates (10.53) were slightly higher than female rates (10.39). Indigenous people had the highest mortality rate nationally (13.33), while white people had the lowest (9.20). In Bahia, black individuals had the highest rate (25), followed by mixed-race individuals (8.62). Data for other races were not available for Bahia. **Conclusion:** Bahia had a slightly lower mortality rate than the national average but longer hospital stays. Women and black individuals are at higher risk, with higher hospitalization and mortality rates. These disparities highlight the need for public policies to reduce inequalities and improve access to early diagnosis and treatment of neurotuberculosis. More studies are needed to understand these factors and guide effective interventions.

Neuro-Behçet disease mimicking viral rhomboencephalitis: a case report

Renato Morais Bueno[1], Rudá Alessi[1], Miriam Eva Koch[1], Eduardo de Souza Tieppo[1], Victor Alexandre Dantas de Miranda[1], Ana Claúdia Piccolo[1], Victor Ezaki Alves Silva[1], Guilherme Bitencourt Barbosa[1], Rayanne Pereira Barbosa[1], Atílio Gomes Romani[1]

[1]Faculdade de Medicina do ABC, Santo André SP, Brazil.

Correspondence: Renato Morais Bueno; Email: renatombueno@hotmail.com.

Case presentation: A 35-year-old female from São Bernardo do Campo (SP, Brazil) was admitted to hospital due to diplopia associated with headache and drowsiness 15 days previously. On physical examination, she presented bilateral oculomotor involvement, more evident on the left, as well as trochlear and abducens involvement. Initially treated as viral meningoencephalitis, with no clinical response. A cerebrospinal fluid puncture showed an increase in cellularity of 120 (82% neutrophils and 18% lymphocytes), with proteins of 38 and other parameters within the reference value. Rapid molecular test for turberculosis, VDRL and viral serologies in the cerebrospinal fluid were negative. After extensive investigation, with no evidence of an infectious process, methylprednisolone was administered for 5 days, with a significant clinical response. The patient was admitted to hospital 2 years later with recurrence of symptoms and reported oral and genital ulcers. Magnetic resonance imaging of the skull showed hyperintensity in the right thalamus, midbrain and pons on T2 and FLAIR scans, in a "Waterfall sign" - or Cascade Sign - with no diffusion restriction and no contrast uptake, suggestive of an inflammatory process in the brainstem. Other imaging studies and vessels were unchanged. Once again, the patient showed a good response to pulse therapy and, due to the data presented, the hypothesis of Neuro Behcet's was made. **Discussion:** Involvement of the hindbrain is a challenge for neurologists due to the broad spectrum of diseases that can trigger signs and symptoms typical of this area. Following the flowchart of the most prevalent diseases, investigation of the cerebrospinal fluid is essential in these cases, but is often not very elucidating, especially when the etiology cannot be determined, either due to lack of resources or lack of confirmatory tests. In the case above, what contributed to the diagnosis was the set of clinical, anamnesis and imaging findings. It is worth remembering that the "Waterfall Sign" - an involvement of the midbrain on MRI, extending to the thalamus or internal capsule - is a suggestive sign, but not pathognomonic of Neuro-Behçet. Furthermore, the presence of other systemic manifestations, such as oral and genital ulcers, corroborates the diagnosis - having, of course, ruled out other pathologies such as syphilis. Finally, the good response to pulse therapy is another factor that points to the pathology in question. **Final comments:** Investigating autoimmune diseases and central nervous system vasculitis is a challenge for any neurologist. This becomes more evident when there is no specific laboratory test for the pathology. The clinical history and the progression of the disease are essential in these cases for investigation. In this case, the patient scored 5 points on the International Criteria for Behcet's disease (ICBD-2006), requiring at least 4 to make the diagnosis.

Neuro-Behçet with subacute onset accompanied by classic neuroradiological sign: a case report

Ana Luisa Suqueno[1], Pedro Simões dos Santos Pilau[1], Antônia dos Santos Bobrowski[1], Barbara Suman Bahlis[1], Bernardo Sommer Cimirro[1], Guilherme Vanik Pinto[1], Marco Antônio Delazeri[1], Maria Caterina Bortolazo Pepato[1], Maria Paula Hanel[1], Vitor Augusto Cioquetta[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre RS, Brazil.

Correspondence: Ana Luisa Suqueno; Email: analuisasuqueno@gmail.com.

Case presentation: A 57-year-old female patient presented to the emergency department due to weakness and loss of tactile sensation in her right hemibody, with a subacute onset and progressive worsening over the past 3 weeks. Physical examination revealed grade IV hemiparesis and tactile hemihypoesthesia on the right side, associated with hyperreflexia of the ipsilateral bicipital, patellar, and achilles reflexes. Basic laboratory tests and non-contrast head CT were normal. To further investigate, a contrast-enhanced MRI of the head and lumbar puncture with basic cerebrospinal fluid studies were performed. The MRI showed a poorly defined hyperintense lesion on T2/FLAIR and hypointense on T1 with subtle diffusion restriction, extending to the internal capsule, left cerebral peduncle, and ipsilateral superior cerebellar peduncle, crossing the midline at the thalamomesencephalic junction: the waterfall or cascade sign. Cerebrospinal fluid studies were normal. Due to the characteristics of the lesion, additional investigation included another MRI with spectroscopy and perfusion, blast cell search, cerebrospinal fluid cytology, and rheumatological profiling. The new MRI showed no capillary permeability alteration, but demonstrated reduced N-acetylaspartate peak and increased lactate/lipid and choline peaks. Blast cell search and cerebrospinal fluid cytology were negative for malignancy. Rheumatological profiling was normal. Neurosurgical biopsy of the lesion was difficult due to its location. Considering the clinical picture and complementary tests, three main hypotheses were considered: vasculitis (specifically Neuro-Behçet's disease), inflammatory/infectious processes, and low-grade glial neoplasm. Vasculitis, particularly Neuro-Behçet's disease, was deemed the most probable diagnosis. Thus, intravenous pulse therapy with methylprednisolone 1g/day for 5 days was initiated, resulting in significant improvement of the aforementioned complaints. Additionally, maintenance treatment with cyclophosphamide every six months was decided. **Discussion:** Neuro-Behçet's disease can be divided into parenchymal and non-parenchymal types, with the former being more common, presenting with brainstem syndromes characterized by acute or subacute onset, slow progression, and neuroradiological manifestations as described above. Elevated proteins and absent oligoclonal bands in cerebrospinal fluid are characteristic. The disease has a broad variety of differential diagnosis, requiring extensive investigation to exclude similar pathologies. Acute-phase treatment usually involves intravenous methylprednisolone, while maintenance therapy with immunosuppressants aims to prevent relapses. **Final comments:** Neuro-Behçet's disease is a rare condition with extensive differential diagnosis and varied clinical presentations, posing a high risk of morbidity and mortality. Accurate diagnosis and treatment are crucial to prevent major deficits and loss of patient functionality.

Neuro-Behçet's syndrome presenting as hemorrhagic lesions: a case report

Bruna Silva Lima[1], Beatriz Pires Paes[1], Poliana Lima Campos[1], Beatriz Ballarin Costa[1], Anthony Magalhães Morais Santiago[1], Ernane Pires Maciel[1], Camilo Carvalho[1]

[1]Hospital de Base do Distrito Federal, Brasília DF, Brazil.

Correspondence: Bruna da Silva Lima; Email: brunasilval@yahoo.com.br.

Case presentation: A 37-year-old male, smoker, presents episodes of fever, progressive headache, vertigo, weight loss of 6kg, blurred vision in the right eye, and sudden hemiparesis on the right side. At the time, a CT of the brain disclosed a hemorrhagic lesion in the left thalamus, internal capsule, and mesencephalon, and contrast-enhanced cranial MRI showed low-intensity lesions on T1 with areas of hyperintensity, as well as heterogeneous T2 images with areas of hyperintensity/hypointensity on the left cerebral peduncle extending to basal pons, thalamus, and internal capsule. He was then admitted to the hospital 6 months after the initial symptoms and progressed with decreased consciousness, requiring endotracheal intubation. After extensive investigation of the previous pathological history, it was discovered that the patient presented with recurrent painful and ulcerated oral and genital lesions in the past 5 years that were treated as sexually transmitted infections. During his stay at the hospital, he presented new aphthous ulcers and acneiform papulopustular lesions associated with altered inflammatory tests. In this case, the hypothesis of Neuro-Behcet's disease (NBD) was raised, and the patient underwent treatment with Cyclophosphamide and high-dose corticosteroid. He showed neurological improvement and resolution of oral lesions. **Discussion:** Behcet's disease (BD) is a rare autoimmune vasculitis disorder. More prevalent in males aged 30 to 40 years. The most commonly used diagnostic criteria require recurrent oral ulcerations plus two of the following: recurrent genital ulcerations, skin or eye lesions, or a positive pathergy test. NBD is defined as a combination of neurologic symptoms and signs in patients with definite BD. Neurological lesions can be classified into parenchymal, non-parenchymal, and peripheral nervous system involvement. Non-parenchymal lesions involve thrombosis and other stroke syndromes, intracranial hypertension, and meningeal syndromes, being venous sinus thrombosis the most common presentation. Typically, the neurological manifestations result from vasculitis-induced thrombosis, and the most commonly affected region is the mesodiencephalic junction, followed by the pontobulbar region. At the mesencephalic, diencephalic, and pontine levels, thrombosis, necrosis, and rupture of small vessels can cause hemorrhagic lesions. However, intracranial hemorrhages are rare, with most occurring within ischemic lesions. Diagnosis of NBD incorporates clinical symptoms, MRI findings, CSF analysis, and exclusion of other causes since no criteria have been validated. **Final comments:** In cases with suspected NBD in a patient without a previous diagnosis of BD, an extensive guided history and detailed physical exam have to be made. Diagnosis and management can be challenging, especially in cases of atypical presentations such as hemorrhagic lesions, which can delay treatment and worsen the patient's prognosis.

Neuro-chikungunya: a diagnostic challenge

Victor Hugo de Souza Silva Gomes[1], Letícia Leão Alvarenga[1], Danyelle Rute Francisco e Silva[1], Lucas Wilson Matos Gomes[1], Gabriel Santos de Castro[1], Taysa Alexandrino Gonsalves Jubé Ribeiro[1], Denise Sisterolli Diniz[1], Aracelle Victor do Carmo Faria[1], Delson José da Silva[1]

[1]Universidade Federal de Goiás, Goiânia GO, Brazil.

Correspondence: Victor Hugo de Souza Silva Gomes; Email: victorhhugo2005@gmail.com.

Case presentation: DLAB, 48 years old, female, mixed race, evaluated by the Neurology Service in May 2024 with a history of asthenia, hyporexia, fever (38-38.5°C), myalgia and polyarthritis more than 1 month ago. As symptoms had persisted for around 10 days, she sought medical attention when she developed a sudden onset of generalized paresthesia followed by descending bilateral paresis and reduced visual acuity in the left eye. She denies altered level of consciousness, behavioral disturbance or epileptic seizures. Upon admission, she

had disproportionate tetraparesis with crural predominance, in the right lower limb, tactile hypoesthesia on the left in the topography of V1 and V2 of the trigeminal and in the right hemibody. She also noted bilateral patellar and achilles hyporeflexia. At the ophthalmological evaluation: signs suggestive of retinitis, with visual acuity 20/25 on the right and 20/200 on the left. The CSF examination showed no other changes, except for detectable Chikungunya PCR. On magnetic resonance imaging: signal changes in the left hippocampus, optic neuritis on the left with signs of inflammatory activity and polyneuroradiculopathy. During hospitalization, the patient progresses with worsening paresis and urinary retention. Pulse therapy was administered with methylprednisolone in addition to immunoglobulin infusion for 5 days. It evolves with progressive improvement in the medullary syndrome and, more slowly, in visual changes. **Discussion:** Chikungunya virus (CHIKV) is an arboviral infection caused by Chikungunya virus, an RNA virus from the Togaviridae family. It typically causes fevers and artharlgias and neurological complications are rare. Encephalopathy is the most common CHIKV-associated neurological complication, however, cases of Guillain-Barré syndrome (GBS), myelitis, neuro-ocular diseases (such as optic neuritis), acute disseminated encephalomyelitis and myeloradiculitis have also been reported. Age has been consistently reported as a significant risk factor for severe manifestation of CHIKV, both in the elderly and in infantis. Recognition of CHIKV in patients with neurologic disease requires an understanding of classic presentation of the virus (fever and arthalgias) in people from endemic regions. The CHIKV IgM can be tested in the serum and CHIKV RNA can be assessed via PCR, which is highly specific. Optimal treatment remains not well defined, but case series of patients with GBS or myeloradiculopathy have shown improvement with steroids or intravenous immunoglobulin, as well as with plasma exchange. There are no specific antiviral agents or vaccines at the moment. **Final comments:** Our case report highlights the fact that CHIKV fever may be associated with diverse neurological dysfunctions and should be investigated in patients who live in endemic areas.

Neurodegenerative profile and MMSE score in patients at a geriatric outpatient clinic

Camila Pezente Dal Toé[1], Debora Dagostin Casagrande[1], Tatiana Pizzolotto Bruch[1], Natalli Studnicka[1], Gabriela Serafim Keller[1], Maria Laura Zanette Naspolini[1], Natália Effting Crema[1], Fabrício Weinheimer Lippert[1], Ana Paula Benedet de Carvalho[1]

[1]Universidade do Extremo Sul Catarinense, Criciúma SC, Brazil.

Correspondence: Camila Pezente Dal Toé; Email: camilapezente@hotmail.com.

Evaluate the neurodegenerative profile of first-time patients seen at a geriatric outpatient clinic. Data were extracted from medical records concerning scores obtained on the Mini-Mental State Examination (MMSE), which assesses cognition, in both healthy patients and those diagnosed with neurodegenerative diseases. The study population consisted of 192 individuals, with a mean age of 76.67 years; 34% had a diagnosis of neurodegenerative disease, with 48.4% of these cases being Alzheimer's disease, which showed cognitive impairment in orientation, registration, recall, and language. In Parkinson's disease, significant findings were noted in orientation, registration, attention and calculation, and language. The use of validated scales during consultations aids in recognizing the needs presented by the analyzed patients. This allows for the identification of which cognitive and functional areas require more attention from healthcare professionals in the recovery and systematization of multiprofessional treatment and in promoting healthy aging.

https://doi.org/10.5327/CBN241160

Neurodemyelinating diseases as a differential diagnosis of ischemic myelopathy with atypical manifestations: a case report

Gabriela da Silva Cremonese[1], Rafael Marques Mendes[1], Cristine Koehler[1], Joana Laurindo da Silva[1], Andre Luiz Pereira Martins[1], Olga Cassol Silva[1], Mariana Costa Borges[1], Maria Eduarda Andreatta[1], Carolina Aparecida Donofrio Santos Costa[1], Gladys Lentz Martins[1]

[1]Hospital Governador Celso Ramos, Florianópolis SC, Brazil.

Correspondence: Gabriela da Silva Cremonese; Email: gabrielacremonese@gmail.com.

Case presentation: A 54-year-old male patient, construction worker, used to experience episodic shock-like sensations through the body for over one year before developing paresis and paresthesia in the upper limbs, progressing to the lower limbs. Due to the worsening of the paresthesia in a "boot and glove pattern", associated with myoclonus in the upper limbs and torso, a neuro demyelinating disease was considered. Electroneuromyography showed an increase in the area of insertion, fibrillation, and fasciculation potentials, with a cluster of fasciculations over the vastus medialis on the right, associated with long polyphasic potentials and reduced muscle recruitment in most motor potentials, and suggested changes in the bulbar and segments paraspinal muscles with signs of active and chronic degeneration of the cervical to lumbosacral segments, more evident in the right hemibody and mainly in the cervical segment and simulating signs of lower motor neuron disease. In addition, non-rhythmic discharges during muscle contraction in the biceps, triceps and dorsal interosseous indicated myoclonus. The myoclonus finding broadened a range of differential diagnoses and represents an uncommon complication of spinal cord infarctions. The MRI indicates radiological signs compatible with ischemia in the internal part of the cervical spinal cord between C4 and C7, predominating in the posterior horns. **Discussion:** Myelopathy refers to any pathological process that affects the spinal cord, often mimicking multiple diseases with rare manifestations. Beyond trauma, the most common etiologies of myelopathy include vascular, autoimmune, infectious, neoplastic, hereditary, neurodegenerative, and idiopathic diseases. As an uncommon symptom of this condition, myoclonias are rapid and involuntary muscle contractions that predominantly represent central nervous system injuries. Spinal cord injuries leading to myoclonus are rare, but they must be taken into consideration for diagnosis and consequently better therapy. **Final comments:** The diagnosis of ischemic myelopathy can be challenging and requires additional tests such as neuroaxis MRI and Electroneuromyography. It is essential to identify the cause of ischemic myelopathy to define the best therapeutic proposal. Therefore, further studies on the different manifestations of this syndrome are essential to bring attention to this differential diagnosis for an effective and early treatment.

Correspondence: Jonas Alex Morales Saute; Email: jsaute@hcpa.edu.br.

Background: Neurodevelopmental disorders are frequently and heterogeneously diagnosed among patients with dystrophinopathies. The clinical manifestation of intellectual development disorder had already been associated with the underlying DMD genotype, however correlation between others frequently diagnosed comorbidities and genotype is uncertain. **Objective:** We aimed to evaluate how the diagnostic of Attention-Deficit/Hyperactivity Disorder (ADHD), Obsessive-Compulsive Disorder (OCD), or Autism Spectrum Disorder (ASD) and patients genotype are related, as well as whether the prevalence of these comorbidities differ among the genotypic subgroups established. **Methods:** Childhood Autism Rating Scale (CARS), Yale-Brown Obsessive Compulsive Scale for Children (CY-BOCS), and Swanson, Nolan and Pelham IV (SNAP-IV) scale were applied to 50 participants and their caregivers, mainly from the Hospital de Clínicas de Porto Alegre (n=38) or other Brazilian centers (n=12). Participants were grouped according to their genotype and affected dystrophin isoforms. **Results:** The overall diagnostic rate for ASD was 34%, similar to OCD (35.5%). Half of the patients (51.4%) were diagnosed with ADHD. Cerebral isoforms were affected in more than half of the participants (52%). The diagnosis of ASD, CARS scores, and diagnosis of OCD were associated with genotype and impairment of cerebral isoforms. ADHD diagnostic rates were elevated across all the genotypic groups and showed no association with muscular or cerebral isoforms. **Conclusion:** Our results show that patients with DMD and impairment of cerebral dystrophin isoforms have an increased risk for ASD and OCD, and the identification of a patient with a genotype that affects these isoforms should prompt neuropsychological assessment and multidisciplinary follow-up.

Neurogenetic intersection: a fascinating CMT-CIDP overlap in a Brazilian cohoort

Carolina Braga Moura[1], Ana Luiza Morgado Costa[1], Maria Clara Lemes[1], Gabriel Thomaz Candido[1], Gabrielle Sales[1], Camila Castelo Branco Pupe[1], Osvaldo Jose Moreira do Nascimento[1]

[1]Universidade Federal Fluminense, Niterói RJ, Brazil.

Correspondence: Ana Luiza Morgado Costa; Email: anamorgado@id.uff.br.

Discerning inherited neuropathies from CIDP, particularly in instances with a subacute onset, poses a diagnostic challenge. In the presence of cases with non-classical clinical findings of CMT, it is important to clinically suspect other entities such as CIDP. It is necessary to search for mutations, such as in the PMP22 gene. **Case presentation:** We described four patients exhibiting the CMT phenotype, including three siblings. The eldest, a 51-year-old female, experienced a subacute onset of proximal weakness at 40 years old, a nerve conduction study demonstrated conduction block, alongside a cerebrospinal fluid analysis indicating albumino-cytological dissociation. These findings led to the diagnosis of CIDP, for which she received IVIG treatment resulting in partial symptom improvement. The second sibling, a 48-year-old female, received a CIDP diagnosis at 30 years old, confirmed by CSF analysis and nerve conduction study, also experiencing improvement after IVIG treatment. The youngest brother presented inflammatory CSF and proximal weakness at 39 years old, with improvement observed following glucocorticosteroid therapy. A fourth patient from our outpatient clinic not belonging to this family nucleus, aged 46, began presenting symptoms in

childhood with changes in gait, accompanied by frequent falls; at 30 years old, an investigation was initiated due to worsening weakness patterns, resulting in a diagnosis of CIDP via NCS and CSF. **Discussion:** All four patients underwent genetic testing for hereditary neuropathies. On physical examination, all four exhibited bilateral pes cavus, legs with an inverted champagne bottle appearance, balance issues, while the three siblings had distal atrophy, and the fourth patient had scoliosis . All tests confirmed CMT 1A with pathogenic mutation in PMP22. The eldest sister demonstrated significant balance impairment and carried a heterozygous PMP22 mutation at chr17:14.236.572 - 15.574.201, while the other sister primarily struggled with neuropathic pain and possessed a PMP22 Gain (Entire coding sequence) copy number of 3. The youngest brother faced progressive balance difficulties and weakening over subsequent years, with a PMP22 mutation at chr17: 14.095.305 - 15.492.541. The fourth patient, similar to the youngest, presents a pattern of imbalance and loss of strength and carries a duplication of the PMP22 gene. **Final comments:** This scenario unveils a rare overlap of CMT and CIDP within a group, underscored by PMP22 mutations. Despite distinct clinical diagnoses, genetic testing provided unequivocal confirmation of this intriguing overlap, shedding light on the complex interplay between genetic neuropathies and CIDP.

https://doi.org/10.5327/CBN241163

Neurogenic stuttering as a clinical manifestation of acute ischemic brain stroke: a case report

Moacir Pereira Leite Neto[1], Ricardo Queiroz Gurgel[2], Kelly Rejane Leite Figueiredo de Oliveira[3], Cláudio Gleidiston Lima da Silva[1], Isabel Felipe Vásquez[1]

[1]Universidade Federal do Cariri, Barbalha CE, Brazil.
[2]Universidade Federal de Sergipe, São Cristovão SE, Brazil.
[3]Afya Educação Médica, São Paulo SP, Brazil.

Correspondence: Moacir Pereira Leite Neto; Email: moacir.leite@ufca.edu.br.

Cerebrovascular accident (CVA) can cause various neurological deficits affecting speech. We report the clinical case of a woman, who presented neurogenic stuttering as a sequel after an acute ischemic stroke. **Case presentation:** C.O.A, 63 years old, female, married, farmer, from Iguatu-Ce. On 2013 december, she suddenly presented "sensations of numbness in the left side of the face and heaviness in the tongue", mild dysarthria and stuttering that was unusual for the patient until then. In 4 days, only the stuttering persisted. Previously, she was a smoker, had high blood pressure and was diabetic. On general physical examination there were no changes, and the neurological examination of the superior cortical functions was normal, but speech was developed with difficulty. Assessment of the motor system, sensitivity, balance, normal gait and coordination. Complementary exams revealed normal electrocardiogram and echocardiogram, Doppler of the carotid and vertebral arteries showed calcified atheromatous plaques in the right internal carotid artery, causing stenosis of less than 50%, and in the left internal carotid artery, causing 55% stenosis. Laboratory tests performed showed normal blood count, AST, ALT, sodium, potassium, calcium, urea, creatinine, triglycerides and uric acid, LDL cholesterol 145, fasting blood glucose 122. Skull MRI revealed T2 and FLAIR hyperintensity in the left superior and middle frontal gyri, without restriction to diffusion, due to ischemia in the territory of the left middle cerebral artery, and ischemic microangiopathy. **Discussion:** Stuttering is a disorder characterized by disturbances in the normal flow of speech fluency, causing blockages and prolongations in the sounds of words. The neural circuits underlying stuttering as a symptom associated with stroke injury remain unknown, however available evidence suggests that stuttering is not localized to a specific focal region, but rather is the result of a disruption at any level of the cortico-striato-integrative pathway. cortical layer that mediates the execution of speech, and has been described as a symptom of subcortical and cortical infarctions in all lobes, which may be due to disarticulation of speech or impairment of phonology processing. In this case, the presence of sequelae of the neurogenic stuttering type was concluded after an acute ischemic stroke in the left superior and middle frontal gyri, and ischemic leukomicroangiopathy. It was recommended to use acetylsalicylic acid 100 mg per day, atorvastatin 40 mg per day, adjust antihypertensive and hypoglycemic medications, and speech therapy. **Final comments:** A stroke can cause focal neurological deficits that can cause various manifestations, including communication problems, and stuttering is a not very common symptom, whose pathophysiology requires further study, and which requires medical attention for referral to rehabilitation treatment speech therapy.

Neurolinfomatosis secondary to Burkitt lymphoma

Leonardo Villaverde Buback Ferreira[1], Larissa Braga Mendes[1], Daniel Delgado Seneor[1], Gabriela Rodrigues Tomaz[1], Lara Santos Machado[1], Lucas Toshio Uenishi[1]

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Leonardo Villaverde Buback Ferreira; Email: leonardo.buback@gmail.com.

A 33 year-old man was admitted referring diplopia initiated 1 month prior and insidiously worsening in the following weeks, associated with weakness in both upper and lower limbs, face and with intense lumbar pain. On examination he had lost weight, had inguinal palpable lymphonodes, left ptosis, ophtalmoplegia and midriasis; and right ophtamoparesis with only partial abduction of the eye spared. He had facial diplegia and right hemiface hypostesia, right jaw deviation upon opening and right palatal paresis. An asymmetric tetraparesis was evident, worse in the right upper limb and left lower limb, not being able to offer resistance in any of the four limbs. Deep tendon reflexes were absent and he exhibited intense lumbar pain upon lower limbs movements. His MRI of the brain, cervical, thoracic and lumbosacral spine demonstrated thickening and contrast enhancement at multiple cranial nerves and spinal roots, in addition to leptomeningeal enhancement. A lumbar puncture with cerebrospinal fluid analysis showed 880 cells with atypical characteristics, identified through immunophenotyping as mature B lymphocytes. A bone marrow biopsy was obtained, confirming the presence of a malignant mature B cell neoplasm expressing CD10 and CD38 antigens, compatible with the diagnosis of Burkitt Lymphoma, and characterizing the neurological manifestations as a neurolinfomatosis secondary to the infiltration of lymphoma cells. Central nervous system lymphomas can be further categorized as primary or secondary to systemic disease, as in the present case. In the latter situation, 90% are due to diffuse large B cell lymphoma, and 10% to other types, like T cell lymphomas and Burkitt lymphomas. Their most common neurological manifestations are focal deficits, mental state changes, intracranial hypertension, epilepsy and visual alterations. Up to 40% of central nervous system lymphomas present on imaging as unique or multiple parenchymatous lesions, with restricted diffusion, contrast enhancement and minimal perilesional edema. The leptomeningeal involvement is seen in up to 30% of cases, being more common in secondary lymphomas. Neurolinfomatosis, the cranial nerve, spinal roots and nerves infiltration is rarely seen. The central nervous system secondary infiltration is a severe complication of systemic hematological neoplasms, with multiple possible presentations, among those the rare neurolinfomatosis.

Neurological challenges in Burkitt lymphoma: a case of methotrexate-induced myelopathy or central nervous system invasion?

César Minoru Toita Koga[1], Anne Caroline de Brito Edir[1], Elenaide Coutinho Nunes[1], Francisco Manoel Branco Germiniani[1], Hélio Afonso Ghizoni Teive[1], Sâmia Talise El Horr de Moraes[1], Gabriel Abrahão Stoliar[1], Camila Emi Fujiwara Murakami[1], Luis Daniel Silva Pilatti[1], Caio César Diniz Disserol[1,2,3]

[1]Universidade Federal do Paraná, Hospital de Clínicas, Curitiba PR, Brazil.
[2] Instituto de Neurologia de Curitiba, Curitiba PR, Brazil.
[3]Hospital Israelita Albert Einstein, Curitiba PR, Brazil.

Correspondence: César Minoru Toita Koga; Email: cesarmtkoga@gmail.com.

Case presentation: A 57-year-old male presented with progressive subacute gait impairment, bilateral lower limb numbness, and urinary incontinence. Physical examination revealed impaired pain, vibration, and position sense with a T10 sensory level, brisk deep tendon reflexes in the lower limbs, mild paraparesis, and bilateral extensor plantar response. The patient had been recently diagnosed with Burkitt lymphoma with bone marrow involvement and multiple bone lesions and was undergoing treatment with hyperfractionated cyclophosphamide, vincristine, doxorubicin, dexamethasone, methotrexate and cytarabine chemotherapy (hyper-CVAD regimen), along with alternating intrathecal injections of methotrexate (ITM) and cytarabine for CNS prophylaxis. Symptoms were mild and nonspecific at first, but worsened after the first ITM doses and became severe after the sixth cycle. Laboratory results and cerebrospinal fluid (CSF) with immunophenotypic analyses were unremarkable, including normal levels of vitamin B12 and homocysteine. Magnetic resonance imaging (MRI) of the thoracic spine revealed new longitudinally extensive T2-weighted hyperintensities in the posterior and lateral columns of the thoracic spinal cord, consistent with methotrexate-induced myelopathy. Empiric replacement of vitamin B12 and folate were administered, but no improvement was observed. At the end of the initially proposed therapy, the patient developed complete oculomotor nerve palsy in the right eye. Brain and orbit MRI along with new CSF with immunophenotypic analyses disclosed no new findings. Brain vascular neuroimaging was unremarkable. Neuroaxial MRI revealed improvement of bone lesions, but no new CNS findings. Due to the neurological symptoms, empirical treatment with high-dose intravenous methotrexate was initiated. A whole-body PET scan one month later showed new diffuse bone lesions, and the patient succumbed three months later due to systemic complications from the hematological disease. **Discussion:** This case highlights the complex neurological manifestations in Burkitt lymphoma patients undergoing chemotherapy. It remains unclear whether the patient experienced ITM-induced myelopathy, CNS lymphoma infiltration, or both, given the limitations of CSF analysis and neuroimaging accuracy. ITM is commonly used in hematological malignancy treatment, yet its neurotoxicity can lead to rare neurological complications, such as subacute myelopathy, in 0.8% to 3% of cases. In our patient, initial symptoms worsened post-ITM, suggesting potential neurotoxicity. However, subsequent oculomotor nerve palsy and poor prognosis raised suspicion of lymphoma spreading along the CNS. The lack of highly accurate and specific biomarkers hinders differential diagnosis of CNS lymphoma, delaying early targeted interventions. **Final comments:** Future advancements in biomarker profiling and imaging technologies are crucial to improve outcomes in these complex cases involving aggressive blood marrow neoplasms.

https://doi.org/10.5327/CBN241166

Neurological complications of cerebrospinal fluid hypotension: a case of cerebral venous thrombosis

Eduardo Rosa da Silva[1], João Victor Meneses de Aguiar[1], Laís Bissoli Perini[2], Bruna Garcia da Silveira[3], Adaucto Wanderley da Nóbrega Junior[1], Bruna Macena Cutti[1], Edson Pilotto Duarte[1]

[1]Hospital Homero de Miranda Gomes, São José SC, Brazil.

Correspondence: Laís Bissoli Perini; Email: laisbperini@hotmail.com.

Cerebral venous thrombosis is a rare complication of spontaneous intracranial hypotension (SIH). The primary symptom of SIH is severe headache worsened by orthostatic positioning and improved by lying down, often accompanied by cervical pain, nausea, and auditory changes. Diagnosis is confirmed by cerebrospinal fluid opening pressure <6cm H2O and/or evidence of cerebrospinal fluid leakage on imaging studies. Etiology can be spontaneous or secondary to trauma or medical procedures, with cerebral venous thrombosis being a rare complication of this secondary headache type. **Case presentation:** A 38-year-old female presented with fronto-parietal headache associated with neck pain, unresponsive to common analgesics, worsened by orthostasis and relieved by recumbency. There was no alteration in consciousness, fever, or ear pain. She had a history of migraines for 8 years, managed with amitriptyline with good response to prophylactic therapy. There was a change in the characteristics and intensity of the headache compared to her usual pattern. A history of post-spinal anesthesia headache 10 years ago resolved after a blood patch. She denied hormonal contraceptive or therapy use. Neurological exam was unremarkable. Laboratory tests, including negative thrombophilia screening (AntiBeta2glycoprotein IgM and IgG, antiCardiolipin IgG, Lupus anticoagulant, and Antithrombin III 116%), hemogram, and coagulation studies were normal. During hospitalization, she was refractory to optimized combined analgesia. Cranial MRI showed signs of cerebrospinal fluid hypotension, small old infarcts in the periphery of cerebellar hemispheres, with cortical vein filling defect in the left paracentral high convexity, indicative of recent venous thrombosis. **Discussion:** Based on clinical history and findings, the diagnosis was cerebral venous thrombosis secondary to cerebrospinal fluid hypotension. Following anesthesiology consultation, she underwent a blood patch with significant headache improvement. She was also started on full in-hospital anticoagulation and discharged for outpatient follow-up, receiving Xa factor antagonist. **Final comments:** This case report highlights the rare occurrence of cerebral venous thrombosis secondary to cerebrospinal fluid hypotension. Early detection, thorough investigation, and identification of potential triggers are crucial for accurate diagnosis and initiation of appropriate treatment.

Background: Neurological diseases are an important cause of morbidity and serious sequelae in Brazilian workers. Many of them need to remain away from their activities for long periods. Public servants do not yet have a fully structured Occupational Health network. It is necessary to have knowledge about the illness profile of this population to choose the best approach to such diseases, whether they are general or specific and related to professional routine. **Objective:** To verify the frequency of neurological diseases associated with prolonged work absence in Brazilian public university employees between 2019 and 2023. **Methods:** It was a cross-sectional study in which a retrospective survey was carried out, including work absences lasting fifteen days or more associated with neurological diseases in the period from 01/01/2019 to 12/31/2023. The following variables were analyzed: gender, occupation and kind of neurological disease. The population was 5,564 public university employees, with a predominance of women (53.8%). The majority of staff were between 31 and 59 years old (75,8%). **Results:** Neurological diseases accounted for 3.5% of the total of 5,197 absences due to illness over the five years of the study. The frequency in women was 3.5% (132/3844) and 3.7% (51/1353) in men. The year with the highest incidence was 2022, corresponding to 25.1% (46/183) of the total cases and the lowest was 2020, with 13.6% (25/183). Cerebrovascular diseases in women corresponded to 26.5% (35/132) of absences and in men they corresponded to 47.05% (24/51). There was also emphasis on weakness caused by migraines, which affected 20.4% (27/132) of women, and mononeuropathies, which affected 13.7% (7/51) of men. Illness among healthcare professionals was more frequent among women, ranging from 42% in 2019 to 86% in 2020, with nursing assistants being the most affected position. In men, there was a similarity between absences among health, teaching and administration professionals. **Conclusion:** There was a high frequency of absences due to cerebrovascular diseases in men and women. Such diseases have a great potential for morbidity and risk to life. A high frequency of involvement of health professionals was noted, especially among women. Preventive measures and health promotion programs must be adopted to protect and rehabilitate the population of workers identified as more vulnerable to neurological problems.

Neurological health of refugees in Brazil: results and perspectives

Diogo Haddad Santos[1], Flávia Esper Dahy[1], Maria Aldilene Gonçalves[1], João Eduardo Nunes Salles[1], Fares George Abdelmassih[1]

[1]Associação Médica Líbano-Brasileira, São Paulo SP, Brazil.

Correspondence: Diogo Haddad Santos; Email: dhaddadsantos@gmail.com.

Forced migration is a growing reality worldwide, and Brazil has become an important destination for many refugees. According to the latest official report from the Brazilian government, the country received 58.628 requests for refugee status recognition in 2023, an increase of 16.4% compared to the previous year. This increase reflects the overcoming of the most severe period of the Covid-19 pandemic and the resumption of migratory dynamics. Most of these requests came from Venezuelans, followed by Cubans and Angolans, highlighting the diversity of nationalities among the applicants. Importance of Neurological Evaluation in Refugees The health of migrants is a global concern affecting millions of people. It is known that migrants face a series of health vulnerabilities due to factors such as poverty, malnutrition, poor living conditions, dangerous work, and psychological problems related to the migration process. These vulnerabilities increase the incidence of communicable and non-communicable diseases, including neurological and psychiatric disorders. Studies indicate that refugees have a higher prevalence of neurological diseases compared to the local population. Chronic neurological diseases, such as epilepsy and cerebrovascular diseases, are common in refugee camps, surpassing infectious neurological diseases. American data show that resettled refugees in the United States of America often present psychiatric comorbidities associated with neurological diseases, such as headaches, sleep disorders, and head trauma. The Saha (Health in Arabic) Brazil project is a philanthropic initiative conceived by Prof. Dr. Riad Younes and developed by the Lebanese Brazilian Medical Association (AMLB) board to provide specialized medical care to refugees in our country. Results Over a period of four years, 43 patients with neurological conditions were evaluated. Most are adults, 33/43 (76.75%), the majority are women, 25/43 (58.14%), and the mean and median age at the time of first care are, respectively, 34.21 (SD 16.25) and 38 years. These patients come from thirteen different countries, the majority from Venezuela, 14/43 (32.56%). The main neurological condition was headache, presented in 18/43 patients (41.86%), followed by epilepsy, 6/43 (13.95%), which was most diagnosed in children and adolescents 4/6 (66.67%). Conclusion Neurological evaluation of refugees is crucial to identify and treat conditions that may be neglected due to migration and resettlement circumstances. The prevalence of neurological diseases and their psychiatric comorbidities among refugees highlights the need for specific and coordinated interventions. The preliminary results of this project underline the importance of comprehensive neurological evaluations in refugees, contributing to the improvement of health and quality of life for this population.

Neurological immune-related adverse events of checkpoint inhibition therapy: insights from a large-scale electronic medical database

Diogo Haddad Santos[1], Fernanda Grôppo Nogueira Herculano[1], Natalia Silva Fernandes[1], Cheng Tzu Yen[1], Ariel Galapo Kann[1], Ana Carolina Gomes[1]

[1]Hospital Alemão Oswaldo Cruz, São Paulo SP, Brazil.

Correspondence: Diogo Haddad Santos; Email: dhaddadsantos@gmail.com.

Background: Immune checkpoint inhibitors (ICIs) have revolutionized cancer therapy by enhancing the immune system's ability to recognize and attack tumor cells. Despite their clinical benefits, ICIs are associated with a range of immune-related adverse events (irAEs), including neurological toxicities. Our study, with a cohort of 114,317 patients, significantly surpasses all the previous studies, providing a more comprehensive understanding of the neurological adverse effects associated with ICIs. TriNetX is a global federated health research network providing access to electronic medical records, across large healthcare organizations (HCOs). This study leverages data from the Global Collaborative Network, which includes 119 HCOs. **Objective:** To evaluate the incidence, types, and severity of neurological adverse effects in this population. **Methods:** Identify patients treated with ICIs and setting up and running the analysis by defining the index event, outcomes criteria, and the time frame for the analysis. The analysis included four types: Risk, Survival, Number of Instances, and Lab Result Distribution. Inclusion Criteria: Patients must have received any of the following medications: pembrolizumab, atezolizumab, avelumab, cemiplimab, durvalumab, ipilimumab, nivolumab,

dostarlimab, relatlimab, tremelimumab, or retifanlimab. Exclusion Criteria: Patients must not have had diagnoses of the neurological diseases before the use of the ICIs. Outcomes were analyzed from 1 day to 60 days after the index event. **Results:** The analysis revealed the incidence rates of neurological immune-related adverse events (n-irAEs) among the cohort of 114,317 patients treated with immune checkpoint inhibitors (ICIs). The composite outcome of n-irAEs was observed in 3,643 patients, representing a risk of 0.032. Within this group, several specific events were identified. Encephalitis was observed in 114 patients, corresponding to a risk of 0.001. Demyelinating diseases were identified in 91 patients, also corresponding to a risk of 0.001. Meningitis occurred in 161 patients, with a risk of 0.001. Neuromuscular junction disorders were recorded in 327 patients, with a risk of 0.003. Although the specific number of patients and the corresponding risk for polyneuropathies were not detailed here, they are included in the composite outcome of n-irAEs. Similarly, the specific number of patients and the corresponding risk for skin-limited vasculitis were not detailed here, but they are part of the composite outcome of n-irAEs. **Conclusion:** This study, utilizing the largest cohort available in the literature provides a comprehensive analysis of the neurological adverse effects associated with ICIs in oncology patients. The findings underscore the importance of vigilant monitoring and proactive management of these adverse effects to optimize patient outcomes.

Neurological manifestations in chikungunya fever: a systematic review

Pedro Lucas Grangeiro de Sá Barreto Lima[1], Pedro Vitor Ferreira Rodrigues[1], Leonardo José Rodrigues de Araújo Melo[1], Lucas Soares Radtke[1], Emanuel de Assis Bertulino Martins Gomes[1], Sophia Costa Vasconcelos[1], Pedro Henrique Azevedo Damascena[1], Júlia Viana de Castro[1], Francisco Luciano Honório Barreto Cavalcante[1], Paulo Ribeiro Nóbrega[1]

[1]Universidade Federal do Ceará, Fortaleza CE, Brazil.

Correspondence: Pedro Lucas Grangeiro de Sá Barreto Lima; Email: pedro.lucas@alu.ufc.br.

Background: Chikungunya is an arboviral infection caused by the Chikungunya Virus (CHIKV) and is typically transmitted to humans by infected Aedes spp. mosquitoes. The disease is distributed worldwide, occurring more often in outbreaks in Asia and Americas. Neurologic involvement is highly heterogeneous, with manifestations involving the central and peripheral nervous systems. Information regarding the effective burden of this impairment is still lacking. **Objective:** To summarize the existing data on neurological manifestations of this arbovirus, providing new insights on prevalence and characterization. **Methods:** A systematic review and meta-analysis were conducted according to the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) reporting guideline. We included studies with patients diagnosed with Chikungunya by acute serology or PCR who developed neurological manifestations during or after the disease course. Articles reporting patients with headache as only neurological manifestation were not included. **Results:** A total of 126 unique articles out of 1941 were included for review. These articles enrolled 2970 patients presenting neurological impairment caused by CHIKV. The overall incidence of neurological manifestations in CHIKV varied from 16.3 to 75% of the patients. A study reported a cumulative incidence rate of 8.6 per 100,000 persons of neurological CHIKV in the general population during an outbreak. Most patients present these manifestations in the first week of the disease. However, a minority of patients may exhibit impairment weeks or even months after the initial infection. The main reported neurological manifestations of CHIKV are encephalitis, myelopathy, peripheral neuropathy, myeloneuropathy, and myopathy. Other conditions, such as isolated cranial neuropathy, chronic neuropathic pain, horner syndrome and hemorrhagic stroke may occur much less frequently. The infection may also act as a trigger for other neurological dysfunctions, being associated with manic episodes in bipolar disorder patients, generalized anxiety disorder and autoimmune encephalitis. Few articles have reported specific neuroimaging features in neurological CHIKV. The "glass eel sign" is a radiological pattern of spinal cord lesion presenting with peripheral hypersignal on T2 images and central sparring. The "boomerang sign" is characterized by hyperintensity of the splenium of corpus callosum also in T2 imaging. Both of these signs are consistently reported in cases of CHIKV infection. **Conclusion:** We systematically reviewed the neurological disorders caused by CHIKV infection, describing the prevalence and characteristics of the main associated manifestations. Larger samples of the most uncommon manifestations are still necessary to provide a proper description of the whole CHIKV spectrum. This knowledge helps to identify future Neurological CHIKV cases and to improve the outcomes of the patients.

Neurological manifestations in the context of dengue

Ana Vitória Alves de Souza Gripp Laizo[1], Mariana Vaz de Melo Diniz[1], Eustaquio Claret dos Santos[1], Anderson Noboru Mitsui[1]

[1]Hospital Socor, Belo Horizonte MG, Brazil.

Correspondence: Ana Vitória Alves de Souza Gripp Laiz; Email: anavitoriagripp@hotmail.com.

Background: During the second quarter of 2024, there was an increase in the number of dengue cases and associated complications, including involvement of the central nervous system. Diseases reported in the literature include encephalopathy, ischemic and hemorrhagic stroke, polyneuropathies, among others. **Objective:** To analyze neurological manifestations in patients with dengue fever, treated at a private hospital in Belo Horizonte - MG, between February and May 2024, and compare them with the literature. **Methods:** This was a descriptive, retrospective study conducted through the review of medical records from February to May 2024. **Results:** During the study period, 15 cases of neurological manifestations due to dengue were observed. These included 5 cases of encephalitis (33.33%), two cases of refractory migrainous headache (13.33%), one decompensation of a patient with multiple sclerosis (6.67%), two decompensations of patients with epilepsy (13.33%), one hemorrhagic manifestation of dengue with subarachnoid hemorrhage (6.67%), one patient with transient intracranial hypertension with VI nerve palsy (6.67%), one case of ischemic stroke (6.67%), and two cases of transient ataxia (13.33%). The age of patients ranged from 19 to 87 years, with a mean age of 62 years. Male patients predominated (66.67%) over female patients (33.33%). Common comorbidities included systemic arterial hypertension, diabetes, epilepsy, and history of previous ischemic stroke. Most patients fully recovered from their symptoms (86.67%), while a small portion experienced partial resolution (13.33%). There were no fatalities. Regarding the temporal relationship between neurological symptoms and dengue fever, both were concurrent in 11 cases (73.33%), while in 4 cases (26.67%), neurological symptoms followed dengue fever immediately. **Discussion:** A review of the literature reveals that the incidence of neurological manifestations of dengue varies widely, with encephalitis predominating, consistent with findings in this study. An important consideration is the lack of specific treatment directed at the arbovirus itself, particularly in cases of encephalitis, necessitating supportive care focused on complications such as epilepsy, headache, subarachnoid hemorrhage, and ischemic stroke. Ischemic strokes pose a challenge in terms of the risks associated with antiplatelet therapy, particularly in the context of thrombocytopenia. **Conclusion:** Based on the present analysis, there is a clear need for thorough diagnostic investigation, including dengue testing, in patients presenting with acute neurological conditions in the current epidemiological context. Additionally, the importance of neurological monitoring and appropriate ancillary testing for patients already diagnosed with dengue is underscored. Lastly, further studies are needed to explore the treatment of such conditions.

Neurological manifestations of leprosy: a complex clinical case

Isabelle Pastor Bandeira[1], Catarina Dantas Corrêa[1], Camila Emi Fujiwara Murakami[1], Mariana Marques Wolski[1], Allinson Lidemberg Ribeiro[2], Caio César Diniz Disserol[1], Paulo José Lorenzoni[1], Marcos Christiano Lange[1], Rosana Hermínia Scola[1], Carlos Eduardo Soares Silvado[1]

[1]Universidade Federal do Paraná, Complexo do Hospital de Clínicas, Curitiba PR, Brazil.
[2]Universidade Estadual de Ponta Grossa, Ponta Grossa PR, Brazil.

Correspondence: Isabelle Pastor Bandeira; Email: isabellepbandeira@gmail.com.

Case presentation: O.L., a 63-year-old man, presents a complex medical history marked by progressively worsening neurological symptoms since 2017. His previous medical conditions included hypertension, dyslipidemia, and an ischemic stroke at age 50. In May 2019, the patient began experiencing burning sensations in his hands, noted only after the appearance of blisters, without accompanying pain. This hypoesthetic symptom progressed from distal to proximal areas, now affecting both upper limbs up to the middle third of the arms, accompanied by a sensation of swollen fingers. Subsequently, he reported burning on the sole of his right foot in January 2020, coinciding with initial signs of foot anesthesia. By November 2021, burning sensations became frequent, with worsening anesthesia in both lower limbs extending up to the knees, associated with reports of imbalance but no falls. Upon admission to our service, we encountered an elderly patient with asymmetric reduction of superficial and deep sensitivity, progressively worsening over 6 years. Further investigation revealed length-dependent peripheral neuropathy, predominantly involving small fiber impairment. The final diagnosis was neuropathy due to Multibacillary Leprosy (10% intact bacilli) with Type 1 leprosy reaction. Multidrug therapy treatment commenced promptly on September 5, 2023. **Discussion:** Leprosy, or Hansen's disease, manifests in diverse clinical forms, ranging from mild skin lesions to severe nerve damage and deformities, as illustrated by this clinical case. This chronic infectious disease, caused by *Mycobacterium leprae*, primarily affects the skin and peripheral nerves, leading to progressive hypoesthesia and loss of sensation. Our patient presentation of burns on hands and feet without pain perception highlights the characteristic insensitivity to injury, a hallmark of leprosy neuropathy. Diagnosing leprosy relies on clinical suspicion complemented by dermatological findings and histopathological confirmation. In this case, the diagnosis of multibacillary leprosy with a type 1 reversal reaction was confirmed through clinical evaluation, EMG findings consistent with sensory-motor axonal polyneuropathy and lymph bacilloscopy. Treatment of leprosy revolves around multidrug therapy (MDT), comprising rifampicin, dapsone, and clofazimine, aimed at eliminating *Mycobacterium leprae* and preventing disability. **Final comments:** This clinical case exemplifies the intricate clinical spectrum and diagnostic complexities of leprosy. By understanding the pathophysiology, clinical presentation, and management challenges highlighted in this case, healthcare providers and policymakers can enhance their approach to leprosy control efforts. Continued research, advocacy, and community-based interventions are essential to achieving sustained progress towards eliminating leprosy as a public health threat globally.

Neurological repercussions in dengue infection: a systematic review

Alice Cristina Souza Cunha[1], Fernanda de Abreu Silva[1], Cristina da Costa Oliveira[1]

[1]Faculdade Santo Agostinho, Vitória da Conquista BA, Brazil.

Correspondence: Alice Cristina Souza Cunha; Email: alicescunha262@gmail.com.

Background: Dengue is the aborvirus with the greatest epidemiological importance in the Brazilian context today, resulting from infection by the arbovirus of the Flaviviridae family, which is transmitted by female vectors of the genus Aedes spp. Associated symptoms may include severe neurological manifestations. The prevalence and pathophysiology of these manifestations still need to be further clarified. **Objective:** To analyze the profile of neurological repercussions in dengue infection. **Methods:** This is a systematic review of the literature, qualitative and descriptive. The PubMed, SciELO and Lilacs databases were used, using the search terms: ("Dengue" OR "Dengue Virus") AND ("Neurologic Manifestations"), selected according to the Health Sciences Descriptors (DeCS) and Medical Subject Headings (MeSH/PubMed). The research included articles with publication dates between 2014 and 2024, available in Portuguese, English or Spanish. Articles published before 2014 and/or in languages other than those mentioned were excluded. **Results:** After a careful analysis of the thematic adequacy of the articles found, in addition to the comparison between the impact factor and Qualis Capes of the scientific journals in which they were published, we selected 12 articles. We were able to observe that the neurological consequences in dengue infection are more prevalent in serotypes 2 and 3, although they can also occur in serotypes 1 and 4. The pathophysiological mechanism involves disruption of the blood-brain barrier and hematogenous invasion by the pathogen, followed by activation of factors autoimmune diseases that trigger metabolic and bleeding disorders. The main complications detected were: (i) encephalitis; (ii) generalized cerebral edema; (iii) or focal cerebral edema. In addition to these, other less common neurological problems associated with dengue were also mentioned, namely: (i) Guillain-Barré Syndrome; (ii) Miller-Fisher syndrome; (iii) Acute Disseminated Encephalomyelitis; (iv) Neuromyelitis Optica; (v) and Cerebellitis. We also identified conditions considered rare, such as: (i) hypokalemic paralysis, a rarely described record, where there is potassium equal to or less than 3mmol/L, with acute onset of flaccid quadriplegia without cranial nerve palsy; (ii) and parkinsonism, an extremely rare manifestation of dengue, with only one case recorded in the literature, accompanied by brachial plexopathy, multiple cranial nerve palsies and ataxia. **Conclusion:** Dengue is a viral infection that can present a complicated evolution, including neural manifestations, with encephalitis and generalized or focal cerebral edema considered the main neurological repercussions. Determining the epidemiological order of these complications is extremely important for early diagnosis and consequent appropriate therapeutic management. Improving pathophysiological knowledge of these possible complications is still necessary.

https://doi.org/10.5327/CBN241174

Neurological repercussions of acute intermittent porphyria and its importance as a differential diagnosis of Guillain Barré syndrome: a case report

Júlio César Soares Barros[1], Antonia Cardoso Silva[1], Guilherme Carvalho de Souza[1], Larissa da Silva Almeida[1], Maria Adélia de Albuquerque Barros[1], Marcelo Augusto Vieira Jatoba[1], Maria Erigleide Bezerra da Silva[1], Isabelle Galvão de Oliveira[1], José Maria Gonçalves Fernandes[1], Fernando Tenorio Gameleira[1]

[1]Universidade Federal de Alagoas, Maceió AL, Brazil.

Correspondence: Júlio César Soares Barros; Email: julio.barros@famed.ufal.br.

Case presentation: A 28-year-old woman presented with fever, nausea, vomiting, and right iliac fossa pain for one month. She was referred to the surgical emergency service, where she underwent an appendectomy due to suspected acute appendicitis. One week later, she developed nausea, abdominal pain, occipital headache, and progressive ascending paresis in the lower limbs (LL), with significant difficulty in walking. She progressed to respiratory failure and was admitted to the ICU with suspected Guillain-Barré Syndrome (GBS) and Acute Intermittent Porphyria (AIP). Neurological examination revealed isocoric and photoreactive pupils, paraparesis (muscle strength grade I in LL), muscle strength grade III in upper limbs, moderate hypopallesthesia in LL, and preserved superficial sensitivities. Plantar and patellar reflexes were present, while other reflexes were absent. Cerebrospinal fluid analysis ruled out GBS hypothesis (no albumin-cytological dissociation), and darkening of urine after sun exposure strengthened AIP possibility. A 24-hour urine test confirmed the diagnosis with positive delta-aminolevulinic acid and porphobilinogen. Initial treatment included a carbohydrate-rich diet, but hematin was not used due to supply issues. The drug was later introduced into therapy, but the patient was already in a critical state, evolving with tetraplegia, dysautonomia (inappropriate sinus tachycardia), worsening respiratory failure, persistent seizures, and death. **Discussion:** AIP is a rare autosomal dominant disease characterized by an enzyme deficiency in heme biosynthesis. This condition leads to the accumulation of harmful precursors causing severe neurovisceral and neurological symptoms. The porphyric crises can mimic acute abdomen and neurological disorders such as GBS. In this case, cerebrospinal fluid analysis helped rule out GBS. Urine darkening after sun exposure supported the AIP hypothesis, as exposure to sunlight and acidic urine pH can produce porphyrins and other pigments, making the urine appear redder. Confirmation came with the presence of porphyrin precursors in the 24-hour urine test. The initial treatment with a carbohydrate-rich diet and intensive care measures did not yield a satisfactory clinical response, necessitating the introduction of hematin in therapeutic management. This medication is essential as it suppresses the production of porphyrin precursors. The difficulty in obtaining hematin and its late introduction contributed to the unfavorable outcome in this case. **Final comments:** The central and peripheral nervous systems can be affected in AIP, leading to peripheral neuropathies, seizures, dysautonomia and neuropsychiatric manifestations. Symptoms in common with GBS, such as progressive muscle weakness and respiratory failure, highlight the importance of including AIP in your differential diagnosis in order to ensure early and adequate treatment.

https://doi.org/10.5327/CBN241175

Neurological symptoms in a renal transplant patient: a case report

Gabriela Rodrigues Tomaz[1], Fernanda Lustosa Cabral Gomez[1], Lara Santos Machado[1], Luiz José Malta Gaia Ferreira Júnior[1], Larissa Braga Mendes[1], Fabiano Moulin de Moraes

[1]Universidade Federal de São Paulo, São Paulo SP, Brazil.

Correspondence: Gabriela Rodrigues Tomaz; Email: gabirodriguestomaz@gmail.com.

Case presentation: A 55-year-old male patient was admitted to the emergency room with a three-week history of apathy, difficulty in finding words, and performing daily activities. He had been on leave from work for two weeks due to worsening symptoms. He did not report falls, imbalance, or gait disturbances, remaining independent in basic daily activities. He denied fever, weight loss, and night sweats. The patient had a history of systemic arterial hypertension and diabetes mellitus and had undergone a kidney transplant from a living donor 24 years ago due to chronic kidney disease of unknown cause. He was taking Tacrolimus, Sodium Mycophenolate, Prednisone, Acetylsalicylic Acid, Atorvastatin, Sulfamethoxazole-trimethoprim, oral antidiabetics, and insulin. In the initial neurological examination, the patient was alert but inattentive, with temporal and spatial disorientation, bradyphrenia, ideomotor apraxia, and inexhaustible glabellar reflex. A cranial CT scan showed a lesion in the left frontal lobe with vasogenic edema. Cerebrospinal fluid examination revealed lymphomononuclear pleocytosis, high glucose, elevated lactate, and hyperproteinorachia. Treatment with Ceftriaxone and Metronidazole was started for a possible brain abscess. New CSF tests confirmed positive cryptococcal antigen and positive India ink, indicating cryptococcal infection. Due to suspected cryptococcoma, treatment with Amphotericin B and Fluconazole was initiated. Later, a blood culture revealed Actinomycete, and the treatment was changed to Cefepime and Clindamycin. The patient developed myoclonus, loss of speech ability, and a decrease in consciousness level, requiring intubation and being diagnosed with non-convulsive focal status epilepticus in the left frontotemporal region. After controlling the epileptic state and gradually tapering off sedation, the patient still did not wake up adequately. A repeated CT scan showed no changes from the initial image. With no clinical improvement after three weeks of treatment, a brain biopsy was performed, revealing diffuse large B-cell lymphoma, non-germinal center type, characterizing a post-transplant lymphoproliferative disorder (PTLD). **Discussion:** All lymphomas occurring in patients receiving post-transplant immunosuppression are considered PTLD, with an incidence of 1-20% in transplant recipients. Epstein-Barr virus positivity in the tumor is common (50-80%). Unlike classic lymphoma, extra-nodal involvement is much more frequent. Treatment involves reducing immunosuppression, rituximab, chemotherapy, and other drugs. **Final comments:** In transplanted patients with new neurological symptoms or mental status changes, consider primary CNS PTLD, which occurs in 10% of cases.

https://doi.org/10.5327/CBN241176

Neurology activities in an academic league: an integral tool in medical formation

Luan Nascimento Pereira de Amorim[1], Rafael Hendrick Freitas de Paula[1], Luiz Carlos Figueiredo Filho[1], Francinaldo Lobato Gomes[2], Henrique da Costa Miranda[1]

[1]Universidade do Estado do Pará, Belém PA, Brazil. [2]Universidade Federal do Pará, Belém PA, Brazil.

Correspondence: Luan Nascimento Pereira de Amorim; Email: luanamorim010@gmail.com.

Background: Academic leagues are crucial for enriching medical formation, promoting integration between students and experienced professionals. These student organizations play a fundamental role in complementing the formal curriculum, offering additional opportunities for learning, research, and extension. In this sense, the Academic League of Neurology and Neurosurgery of the State of Pará, founded in 2009, stands out for providing an environment conducive to theoretical and practical study in the area of neurology, which is essential for understanding the pathophysiological bases of neurological diseases and their clinical manifestations. Additionally, it not only enriches students' academic knowledge but also prepares them to face future professional challenges, contributing to the formation of more complete and qualified doctors. **Objective:** To report on the experience of this

academic league as an instrument for the integral learning of medical students and for the deepening of neurological knowledge in undergraduate courses. **Methods:** This is an experience report describing the practical and theoretical activities offered by an Academic League of Neurology and Neurosurgery in the State of Pará. **Results:** The Academic League of Neurology and Neurosurgery of Pará carries out theoretical and practical activities that enrich the training of students. The lectures, given by renowned specialists, cover everything from the development of neurological problems to diagnoses and treatments, providing a comprehensive and up-to-date understanding. Practical activities include weekly internships at a hospital in Belém, where students develop skills in identifying alterations in tests and understanding neurological problems. In addition, the league promotes outreach activities for the public, addressing topics such as headaches, neurodegenerative diseases and epilepsy. Scientific production is encouraged, with the preparation of articles, case reports and presentations at congresses, guided by experienced professionals. To consolidate knowledge, the league organizes courses and symposia on various neurological topics. These activities provide a comprehensive overview of the various cases that a future doctor may encounter in their clinical practice. **Conclusion:** The Academic League of Neurology and Neurosurgery of the State of Pará plays an essential role in preparing students for the medical profession. By offering a balanced combination of theoretical and practical activities, it promotes a significant deepening of knowledge and its application in real scenarios. It also contributes to scientific production and fosters valuable interaction between students and experienced professionals, providing comprehensive academic and professional development and preparing future doctors to face the challenges of neurological clinical practice with competence and confidence.

Neurology first: a challenging case of early rheumatoid meningitis in a previously undiagnosed rheumatoid arthritis

Giovanna Reis Coelho[1], César Minoru Toita Koga[2], Guilherme Faria Cabrera[1], Camila Carneiro Ferreira[3], Catarina Dantas Corrêa[2], Caio César Diniz Disserol[2,3,4]

[1]Universidade Positivo, Curitiba PR, Brazil.
[2]Universidade Federal do Paraná, Hospital de Clínicas, Curitiba PR, Brazil.
[3]Instituto de Neurologia de Curitiba, Curitiba PR, Brazil.
[4]Hospital Israelita Albert Einstein, Curitiba PR, Brazil.

Correspondence: César Minoru Toita Koga; Email: cesarmtkoga@gmail.com.

Case presentation: A 75-year-old man with a history of smoking and treated pulmonary tuberculosis presented to the emergency department with transient aphasia followed by headache and meningeal signs. He was admitted for investigation and, in the next day, experienced his first tonic-clonic seizure. Brain magnetic resonance imaging (MRI) showed bilateral frontoparietal pachymeningeal enhancement, and cerebral spinal fluid (CSF) analysis revealed high protein levels (57 mg/dL) and neutrophilic pleocytosis (30 cells/mm3; 83% neutrophils). Treatment with levetiracetam, ceftriaxone and acyclovir was started. One hour later, the patient developed fever, rash, tachycardia, and dyspnea, which resolved with anti-inflammatory medication and prednisone. Jarisch-Herxheimer reaction and neurosyphilis were suspected. Serum investigation revealed reactive serum treponemal test (IgG FTA-ABS), negative non-treponemal test (VDRL), and positive rheumatoid factor (56 UI/mL), with no history of prior syphilis treatment or joint symptoms. CSF viral panel was negative, and treatment was switched to 14 days of crystalline penicillin. Other infectious and rheumatological tests were negative, including serum IgG4 and interferon-gamma release assay. Later CSF tests for syphilis (IgM and IgG FTA-ABS and PCR) were negative, excluding neurosyphilis diagnosis. Follow-up brain MRI 2 months later was stable, but the patient continued to experience residual headache and developed symmetric peripheral polyarthritis and morning stiffness. Analysis of stored serum collected at admission revealed very high levels of anticyclic citrullinated peptide antibodies (anti-CCP: 500 U/mL; RR: < 17 U/mL), leading to the diagnosis of rheumatoid arthritis (RA). Treatment with corticosteroids and methotrexate resulted in complete resolution of the headache, no further seizures, and normalization of neuroimaging and CSF findings. **Discussion:** RA is a systemic inflammatory disease that can affect extra-articular regions. Among its rare manifestations is rheumatoid meningitis (RM), a challenging diagnosis that can present as focal neurological deficits, headache, neuropsychiatric symptoms, and seizures. Some patients, particularly males, may experience meningitis during the early stages of RA or as its initial manifestation, like in our case report. Diagnosis relies on laboratory and imaging results, including lymphocytic pleocytosis in CSF analysis and frontoparietal pachymeningeal enhancement on MRI. Biopsy may reveal rheumatoid nodules, lymphocytic infiltrate, or vasculitis. Treatment typically involves corticosteroids and immunosuppressive drugs, leading to a more favorable prognosis when started promptly. **Final comments:** Early RM diagnosis is challenging due to its rarity and nonspecific presentation, especially in patients with undiagnosed RA. Clinicians should consider RM in cases of meningoencephalitis with typical MRI findings to enhance patient outcomes and prevent complications.

Background: The non-5q spinal muscular atrophies (SMA) are a clinically and genetically heterogeneous group of hereditary disorders that primarily affect the lower motor neuron, leading to progressive muscle weakness and atrophy. Neuromuscular ultrasound is useful in the differential diagnosis and evaluation of neuromuscular diseases, and different patterns of muscle involvement can point to specific genes. **Objective:** Using a muscle ultrasound protocol, we evaluated patients with proximal and distal forms of non-5q SMA, along with genetic and clinical findings. **Methods:** We selected 21 patients from 19 families with clinical, electrophysiological and genetic findings consistent with non-5q SMA, classified according to the pattern of weakness (predominantly proximal or distal). We developed a neuromuscular ultrasound protocol that evaluated proximal and distal upper and lower limb muscles, axial muscles and diaphragm. Muscle echogenicity was evaluated by the Heckmatt scale, and muscles were observed for 30 seconds for the detection of fasciculations. Diaphragm thickness was measured at deep inspiration and at relaxed expiration, and diaphragm paralysis was defined as the ratio of diaphragm thickening less or equal to 1.2. We composed a heatmap with the muscle ultrasound findings, using the Heckmatt scale score for each muscle. **Results:** Patient's age ranged from 1 to 60 years old (median 33 years old), 15 were male and 6 were female, and the age of onset was congenital in 8 cases. Clinically, 12 patients were classified as proximal (Group 1), and 9 patients were classified as distal (Group 2). Variants were found in 11 patients, in the TRPV4, BICD2, DYNC1H1, VWA1, HINT1 and C19orf12 genes, whereas in 10 cases the genetics studies were inconclusive. The heatmap hierarchical clustering defined 3 patterns of muscle involvement that significantly corresponded (p=0.02) with clinical Group. The first (Pattern A), a diffuse pattern affecting proximal and distal limb muscles, muscles of scapular girdle and axial muscles, was observed in 9 patients, 8 of which were from Group 1 (proximal). The second (Pattern B), a pattern involving predominantly the lower limbs and hand muscles, but also deltoid, latissimus dorsi and rectus abdominis muscles, was observed in 6 patients, 5 of which were from Group 2 (distal). The third pattern (Pattern C) was a milder phenotype, with selective muscle involvement, notably distal lower limb muscles, and was equally represented in Groups 1 and 2. Muscle fasciculations were observed in 12 patients, and there was no statistically significant difference in the number of muscles affected and Group. Only one patient had unilateral diaphragm paralysis. **Conclusion:** The neuromuscular ultrasound protocol was useful in defining the phenotype and differentiating the proximal and distal forms of non-5q SMA. The findings also suggest that proximal and axial muscle involvement in distal SMA may be more common than initially thought.

Background: Neuromyelitis optica (NMO) is a severe autoimmune disease of the central nervous system, characterized by inflammation of the optic nerves and spinal cord. Until recently, there was no treatment with randomized and controlled studies for the disease, and treatment was based on prescribing immunosuppressants based on retrospective studies. **Objective:** To conduct a cross-sectional evaluation of the maintenance treatment offered to patients and the rate of therapeutic failure. **Methods:** A retrospective study of patients diagnosed with NMO with positive anti-aquaporin 4 (AQP4) antibodies at HUCAM was conducted. Treatment refractoriness was defined as the need to discontinue or change treatment due to inefficacy or adverse effects. **Results:** In total, 37 AQP4+ patients were evaluated. Of these, 21 patients (56.76%) used azathioprine as the first choice of treatment. Among them, 9 patients (42.86%) experienced therapeutic failure, resulting in changes in the treatment regimen: 1 patient (4.76%) to mycophenolate; 6 (28.57%) to rituximab. Additionally, 11 patients (29.73%) of the total started treatment with rituximab, and only 1 (2.70%) began with mycophenolate. **Conclusion:** Azathioprine is an accessible therapeutic option for many NMO patients, but the observed therapeutic failure rate of 42.86%, close to that found in the literature, indicates the need for more effective therapeutic alternatives, such as rituximab or those recently approved for the treatment of NMO. Additional studies are needed to identify predictive factors of treatment response and to optimize NMO management.
